dissolute life, without visible means of obtaining an honest livelihood. The observance of these rules is enforced by the police, to whom Acts known as the Prevention of Crimes Acts give large powers. The licence holder is ordered to report himself at intervals to the police, to whom also he must notify any change in his place of residence; he must take care that he is not found in any suspicious locality under suspicious circumstances. A breach of the regulations may entail the forfeiture of the licence, with imprisonment and the obligation to return to a convict prison to serve out the unexpired term of penal servitude. Police supervision by special sentence of a court may be extended in the case of habitual criminals to longer periods than that of the original sentence. An elaborate machinery also exists for the registration of these habitual criminals, and voluminous official records are regularly published and circulated giving detailed information, distinctive marks, and previous history, to enable the police in all parts of the country to identify habitual criminals. A system so rigorous towards offenders who have already expiated their crimes may be deemed to bear heavily on any who have repented of their evil ways and are anxious to turn over a new leaf. To be ever subjected to the intrusive watchfulness of the myrmidons of the law must often increase the licence holder's difficulty of leading an honest life. The struggle is often severe; employers of labour are not too ready to accept the services of "jail birds," and free workmen often resent the admission of an old convict amongst their number. Private charity has happily come forward to diminish or remove this hardship, and many societies have been called into existence for the special purpose of assisting discharged prisoners. The first of these, now honoured with the title of "Royal," was organized in 1856, and had assisted, up to 1879, some eleven thousand prisoners. This society labours chiefly in the metropolis; it is supported by private subscriptions, but it has control also over the gratuities of the licensees who accept its aid. The prisoners on release are first examined at the society's office as to their prospects and wishes; they are given some pocket money out of their own gratuities; and their "liberty clothing," a present from the prison, is changed for more suitable clothes. They are then placed in respectable lodging-houses until in due course employment is obtained for them, after which the society undertakes the reporting to the police, and by its own agents exercises a watchful care over its protégés. There are now upwards of twenty societies established in various parts of the country, and the number is rapidly increasing.

The foregoing system is applicable more particularly to adult males; but for females the rules are much the same as regards imprisonment and penal servitude. But the remission a female convict can earn is greater, and amounts to a third of the sentence, less the separate confinement. Moreover, female convicts whose conduct and character warrant a hope of complete amendment are admitted into "refuges" nine months before the date of their conditional release on leave. There are two of these refuges, which are more like "homes" than prisons,—the Westminster Memorial Refuge at Streatham for Protestants, and the East End House, Finchley, for Roman Catholics. The training of these refuges is calculated to fit the licensee for more complete freedom, and many of the women who go from them into the world do well. The aid societies also help effectually in obtaining situations, often very good ones, for the released female convicts.

Juvenile criminals are now subjected to special treatment. Young offenders, although liable to be treated as adults by the court before which they are brought, are generally dealt with summarily under various powers,

exercised, in some cases in England and Ireland, with the consent of the accused, or, in the case of a child, of the parent or guardian. The discretionary powers of summary courts are wide, ranging in many cases from dismissal (although the charge is proved) to payment of damages and costs, or fine, or limited imprisonment, and in the case of a male child with private whipping either in addition to or instead of any other punishment; and whipping in addition to other punishment may be imposed by all courts on the trial of male offenders under sixteen for the majority of offences. For the very important power of relegating juvenile offenders to reformatory schools and vagrant and neglected children to industrial schools see the separate article, REFORMATORY AND INDUSTRIAL SCHOOLS (*q.v.*).

Juvenile offenders and children while detained in reformatory or industrial schools are not subject to prison discipline, but the rules for the management and discipline of the schools and the detention in them may be enforced by imprisonment. Very beneficial results as regards the diminution of crimes are undoubtedly obtained by various institutions, both public and private. The possible criminal is removed from evil associations while still amenable to better influences; and while still malleable he is taught to labour honestly with his hands. Prison statistics, more especially of the convict prisons, show a marked decrease in the number of youthful offenders in durance, and it is reasonable to suppose that from the causes above mentioned there is a gradual stoppage in the supply. In the ten years between 1871 and 1881 the number in custody of ages between fifteen to twenty-four fell from 2948 to 1957, and this although the general population had increased four millions. The same reduction has shown itself as regards the number of the same ages in local prisons; and it is clear that the improvement is general.

Uniformity in prison discipline is now general throughout the United Kingdom. The Prisons Act of 1877 also extended to Scotland and Ireland, and in both those countries the system of imprisonment for terms of two years and under has been assimilated to that in force in England. As regards penal servitude, convicts pass through the same stages or periods; but Scottish convicts, after undergoing their separate confinement in the general prison at Perth, have been drafted into the English public works prisons. Of late there has been a movement towards securing some of the advantages of convict labour for works north of the Tweed, and it is probable that harbour works will soon be undertaken at one or more points on the Scottish coast. For Ireland, the progressive periods are passed in that country,—separate confinement in Mountjoy prison, public works at Spike Island. The administration of prisons has also been assimilated in Great Britain and Ireland, and has been centralized in each capital under the authority of the state. Boards of prison commissioners in London, Edinburgh, and Dublin, and acting under the immediate orders of the executive, control all local prison affairs, including finance, victualling, clothing, the appointment of officers of all grades, and the discipline of prisoners. The English convicts are still managed by an independent board called the directors of convict prisons, but both commissioners and directors have the same chairman and chief, while the staff of clerks and accountants and storekeepers—in a word, the whole administrative machinery—is identical for both. The welfare of the inmates of all prisons is not, however, left entirely at the discretion of official managers. The local magistracy have still a certain jurisdiction in the local prisons; through elected representatives styled “visiting committees,” they constantly inspect the prisons and exercise supervision over their inmates. They have retained their power to punish and

generally deal with all cases of aggravated misconduct. The functions exercised by these visiting committees might seem to constitute a dual authority in prison management. But so far the two powers have worked harmoniously and well. Since 1880 unofficial and unpaid visitors have also been appointed to undertake an independent inspection of the convict prisons. This practice was introduced, not on account of any administrative failure in the system, but as a safeguard against possible abuses, and to strengthen public confidence. These visitors can give no orders, but they are empowered to make full inquiries into the state of the prisoners and the condition and discipline of the prison.

The sum voted in 1883–84 for convict establishments in England was £414,463, but this includes £18,100 for expenditure in colonies where a few imperial convicts still survive, and grants in aid of colonial magistrates, police, and jails. The vote for local prisons in the same year was £181,852. The returns from male prisoners’ labour in the convict prisons in 1883–84 amounted to £248,993, 11s. 3d. Of this total, £121,956, 5s. 2d. represented the estimated value, by measurement, of labour on public works, and £42,159, 8s. 4d. more the value of prison buildings erected, while the earnings in manufactures amounted to £37,581, 8s. 8d. The balance was the farm and the work performed for the prisons. The female convicts’ labour amounted in the same year to £9933, 9s. 5d., half of which was in washing and manufactures. In the local prisons in England manufactures brought in £39,790, 3s. 11d. The value of the labour on prison buildings was £24,510, 4s. 2d., and that in the service of the prisons £59,562, 0s. 8d. The prison vote in Scotland for 1883–84 was £110,170, the returns from earnings £6000; in Ireland the vote was £145,689 and the earnings £4000. The above terms of expenditure include all outlay—staff (superior and subordinate), maintenance, travelling expenses, &c.

Most civilized nations have considered the question of prison discipline from time to time, and have endeavoured, but with varying degrees of earnestness, to conform to accepted modern ideas as to the proper method of dealing with criminals. The subject has also been dealt with at two international congresses, one of which assembled in London in 1873, and the other at Stockholm in 1878, when views were exchanged and matters of much interest discussed. It is proposed now to supplement the foregoing account of British prison discipline by a brief survey of the prison systems in force in the British dependencies and in various other countries.

*British Colonies and India.*—The prison systems of most of the British colonies have been assimilated as far as possible to that in force in the mother country. In all the larger colonies there are convict prisons and local prisons, and in all cellular separation for the whole or part of the sentence is the rule. This is the case in the Australian colonies, in Tasmania, and in New Zealand.

The prison system of Canada is advanced and enlightened. The numbers incarcerated are not great, and crime is not very prevalent. Six establishments suffice for the Dominion—Kingston, St Vincent de Paul (for the province of Quebec), Halifax, Manitoba, British Columbia, and Dorchester. The last-named has replaced that at St John’s. All these are cellular prisons; and they receive prisoners of all categories, for trial and after sentence whatever the term. Females have a special quarter in each prison. Isolation is strictly carried out for all short sentences; but for the longer labour is in association. A great deal of good work is turned out in the Canadian prisons. All the rolling stock for railways in Government hands, iron-work, clothing, and boots and shoes are produced at the various prisons, but not to an extent to allow all prisoners to be instructed in trades. Most of the prisons possess land in their vicinity which is tilled by the prisoners. There are no prisoners’ aid societies as yet in Canada, although their formation has been earnestly recommended.

For the Cape of Good Hope there is a good prison at Cape Town. In Ceylon, since 1867, cellular separation has been enforced for the whole period of short sentences, and the first six months of long sentences. In Jamaica there are several kinds of prisons, but only the principal, the general penitentiary, has any number of separate sleeping cells.

In India the jails number upwards of 230, with an indefinite number of small lock-ups. There is also the large convict depot at Port Blair in the Andaman Islands. Very few of the Indian jails

are entirely cellular; two in particular may be mentioned, that of Utakamand and that of Hazaribagh, both of which are for European convicts. "The remainder," says Dr Mouatt, formerly inspector general of prisons in Bengal, "are built on every conceivable plan; a large number of them are miserable mud structures, which are constantly being washed away by heavy rain, and as constantly provide work for the prisoners in repairing them." A few of them are radiating, and nearly all provide for the separation by night of the male and female prisoners; and there is a certain rough classification according to sentence. All work is in association, except when prisoners are kept in cells for misconduct. The proportion of cell accommodation, when Dr Mouatt wrote, was barely 10 per cent. Work is mostly intramural, and generally remunerative and industrial. Prisoners are occasionally employed out of doors in gangs upon canals and other public works. The ironing of prisoners where prisons are insecure still prevails as a safeguard against escape. Prison punishments are generally severe, and include flogging, fetters, penal labour, and complete isolation. The whole question of prison discipline in India is strictly subordinated to financial considerations, and the system in consequence lacks uniformity and completeness.

*Austria.*—It was not until 1867 that the Austrian Government declared in favour of a system of cellular imprisonment. Till then all prisoners had been kept in association, but at the date above mentioned a recommendation that separation should be the rule was made to the reichsrath and approved. Owing to the expense of reconstructing or converting prisons, the principle could not be generally adopted; moreover, the Austrian authorities were not in favour of continuous isolation. Hence the practice adopted was a combination of the two methods. Short imprisonments might be endured entirely in separate cells; every prisoner might pass the first part of a long term in a cell, but the isolation was not to exceed eight months, the remainder of the sentence to be undergone in association or collectively, due regard being had to the classification of the prisoners brought together. This classification is based upon the individual's age, education, state of mind, and former life, and the nature of his crime. The progress made in the erection of cellular prisons has not been very rapid. Although the total number of prisoners in Austria-Hungary exceeds 17,000, up to the end of 1879 only 1050 cells had been provided, viz., at Gratz 252, at Stein 348, at Pilsen 387, and at Karthaus 63, while two small prisons for trial prisoners have also been built at Cilli and Reichenberg. These new prisons are, however, very complete and perfect; they have all modern appliances, chapels, hospitals, workshops, and baths; the cells are spacious, and well ventilated, lighted, and warmed. Two days of cellular imprisonment, after three months have elapsed, count as three in association. There is no distinctly penal labour. In separation prisoners follow such trades as shoemaking, tailoring, weaving, button-making, wood-carving; women are employed in embroidery, spinning, quill-pon making, and knitting. In association the principal employments are carpentering, coopering, smith's work, brick-making; and a number of the more trustworthy prisoners have helped to construct railways and lay down roads. As a rule the prisoners' labour is let out to contractors; this plan is preferred as relieving the state of all risks, while officials are more at liberty to attend to the pure disciplinary treatment of the prisoners. As a rule every prisoner who enters ignorant of a trade is taught one in prison. Prisoners can earn substantial wages; where contractors are employed, the prisoners receive half what is paid over, after all costs have been deducted. Half of the earnings may be spent in the prison canteen in the purchase of luxuries, including beer and tobacco, or in the support of a prisoner's family, or in the purchase of clothing to be worn on discharge. There is only one "Liberated Prisoner Aid Society," which is established at Vienna, and which does good service in supporting prisoners until they find occupation, and providing them with money, clothes, and tools. Speaking generally, there are three classes of prisons in Austria-Hungary, viz., for minor offences, and for prisoners sentenced to terms less than one year and to terms of one year and upwards respectively. The treatment of the incarcerated is humane; their diet is sufficient; they have good beds and bedding; the sick are cared for in hospitals; the labour of the able-bodied is not excessive, although supposed to extend over ten hours daily. Religious services are provided for, and non-Roman-Catholic prisoners may be seen by ministers of their own form of faith. Prison administration is under the minister of justice, who delegates his powers to an inspector general of prisons. Commissions of inspection are appointed to visit all the cellular prisons monthly, and there are also local boards of management and control.

*Belgium.*—Prison discipline has perhaps received as close attention in Belgium as anywhere in the world. In 1835, when the great movement towards prison reform was in progress, Belgium first adopted the cellular system experimentally by constructing thirty-two cells in connexion with the old prison at Ghent. After a trial of nine years a verdict was passed in favour of cellular separation and it was authoritatively adopted in 1844. Progress was steady if not rapid; by degrees many cellular prisons were built;

and up to the present date (1885) twenty-four are in existence. A model prison for 600 on the same plan is in process of construction at Brussels, and three others, smaller, will soon be finished. Belgium has unhesitatingly accepted the rule of absolute separation as regards all prisoners, whatever the duration of their sentences. That solitude which disastrous results in England have strictly limited to either nine months, or, under certain modifications, to two years, may be enforced in Belgian prisons for at least ten years. At the end of that period a prisoner may claim to go into association, and they are then removed to Ghent, where they work and eat in company but have separate sleeping cells. Separation, again, is not insisted upon with the sickly, or those whose minds appear weak; while all upon whom cellular imprisonment has failed may also in due course be removed to association. But for the rest the separate system is the invariable rule, and it is carried out with careful and unvarying sternness. The prisoner never leaves his cell save for chapel or exercise; at the former he is in a separate box or compartment; the latter he takes alone in a narrow yard. His life, however, is not one of absolute solitude. He is visited frequently by his warders and schoolmasters and trade instructors; chaplain, governor, and doctor also break the monotony of his life. According to the Belgian view of the case, he "lives in association with the prison staff," not with his fellow criminals. It is claimed for this system, which aims primarily at the reformation of individuals, that no evil consequences have as yet been seen to follow from the treatment. Official statistics may be searched in vain for the record of cases of suicide or of mental alienation; neither are abnormally frequent. On the other hand the Belgian authorities insist that the dread of the punishment has had a marked effect upon crime, and that there is a diminution in the number of second sentences. "Recidivists," or reconvicted prisoners, are, moreover, subjected to a more rigorous discipline.

There are three classes of prisons in Belgium;—the *maisons d'arrêt*, or prisons of detention, for accused persons undergoing examination or awaiting trial; the *maisons de sûreté*, or prisons for the infliction of short sentences; and the *maison centrales*, which correspond to the English convict prisons. Prisoners awaiting trial, and still innocent in the eyes of the law, are treated with much leniency and consideration. An arrangement peculiar to the French and Belgian prisons is the privilege of the "pistole." A prisoner on payment of a certain charge is conceded better accommodation; he has a room, not a cell, decently furnished, and may provide his own food, have books, see his friends, and do no work. Offenders of the better class, and never previously convicted, are sometimes relegated specially to the pistole by the tribunals; and the local boards of visitors have also power to transfer prisoners to this privileged class. Independent of the pistole the law provides three kinds of penalty—correctional imprisonment, seclusion, and imprisonment with hard labour. But, except the slight differences as regards privileges of letters and visits, the treatment is identical in all three categories. It is correctional for all; all prisoners are kept in seclusion; and there is no hard labour, as we understand it. Purely penal labour does not exist in the Belgian prisons. Public works are obviously impossible; and there are no tread-mills or cranks. The labour is entirely industrial; but its object is rather to reform individuals than to produce profit to the state. With strict cellular confinement the range of prison industries is generally limited to sedentary employment; but, besides weaving, tailoring, shoemaking, book-binding, and so forth, various handicrafts are practised. The prisoner's labour is partly let out to contractors, partly utilized by the authorities. A portion of the earnings for work done goes to the prisoners; and part of the money may be spent in the purchase of better food or tobacco, where it is permitted, from the canteen. No pains are spared to instruct the prisoners; those ignorant of any trade are regularly apprenticed and taught, the idea being to provide every one with a means of livelihood on release. The severity, not to say cruelty, of the strict rule of separation is mitigated as far as possible by the paternal solicitude of the authorities. The administrative arrangements of the Belgian prisons are nearly perfect. The buildings are spacious—the halls lofty, light, and airy; the cells are of ample dimensions, carefully ventilated, well-lighted, and well-warmed. An abundant water supply assists the sanitary services; dietaries are sufficient and well-chosen, soup with plenty of vegetables forming an especial feature in them. School instruction is available for all. There are well-supplied libraries. The hospitals are clean and spacious, fitted with every necessary, and the percentage of patients under treatment is usually small. An epidemic of ophthalmia was, however, long present in the reformatory prison of St Hubert. An independent system of visitation is supposed to protect the prisoners from ill usage; local boards composed of local functionaries exercise constant supervision and control over the prisons in their vicinity. The central administration is intelligent; and the prison service being esteemed highly honourable attracts good men to recruit its ranks. Female prisons are exclusively managed by the nuns of some religious order in the locality. Besides the prisons of punishment for adults, there are two establishments in Belgium

which deal exclusively with juvenile crime. These are at St. Hubert in Luxembourg, and at Nemur. The first, dating from 1849, is an agricultural colony which receives all youths up to the age of fourteen; the labour is exclusively in the fields. Young criminals belonging to the towns are sent to Nemur, where the work is mechanical but more sedentary. A good education both moral and practical is received at these reformatories, which are more like schools than prisons. There are also philanthropic schools for vagrants and non-criminal children. At present no societies labour to assist prisoners on release. A complete organization once existed for the purpose, but it was wholly official and those whom it was supposed to benefit suspected and kept aloof from it. It may be added that, although there is no power in the prisoners' own hands of working out remission by steady industry and good conduct, remission may be obtained on these grounds on the recommendation of the prison authorities. All sentences, too, have been shortened since the general introduction of cellular imprisonment; as the treatment was more severe, justice demanded a curtailment of the penalties. Capital punishment, although not definitively abolished, is never inflicted, and all sentenced to death pass into prison for life. But after ten years they too are transferred to Ghent for the remainder of their days.

**Brazil.**—The present emperor of Brazil has long taken an active interest in prison reform. He has encouraged the prison administration of his country to introduce a scheme which is in many respects the same as that in force in England. Prisoners, after sentence, are subjected to a period of three calendar months suffering strict discipline; they then pass to another prison, where cellular separation is still enforced, but the daily labour is in a vocation and discipline. This is styled the reformatory stage; after that comes the third stage, which is reached by marks gained through industry and good conduct. In this last stage, called the training stage, prisoners work together; they may converse, may wear their own clothes, and are under the care and supervision of the most trustworthy of their fellows. They sleep in large dormitories, not in cells, are allowed to cultivate a piece of garden ground on their own account, and a large portion of their earnings is placed to their credit and handed over to them on release.

**Denmark.**—The prison system in force in Denmark dates from 1849, previous to which time the arrangements were extremely unsatisfactory. In the early part of the century Danish prisons were in a deplorable condition as any in Europe; after enduring intolerable horrors, the worst of felons passed on to hard labour in the forests or in the field. But a commission was appointed in 1849 to report and recommended the adoption of the cellular system for all prisoners awaiting trial, and under short-term sentences,—those condemned to long imprisonment to be put to hard labour in association. The necessary prisons were constructed as a rule, within a quarter of a century, of two million of people. There are a large number of small detention prisons, and four principal prisons for the continent; one cellular for males at Trindholm, and two associated at Hjørring and Viborg, one for female confined cellular and associated at Christianshavn. About 75 per cent. of the trials are sent over to separate confinement in cells; its infliction is limited to first offenders, youths, or those sentenced to six months and upwards up three years and a half; the associated or associate system applies to the second offenders, and for terms from two years to life. There is no disciplinary penal labour in the prisons; the industrial pursuits, and it is in the hands of convicts. Prisoners in cells are constantly visited; religious and secular instruction is imparted; the dietaries are carefully calculated, and the inmates generally intelligent and humane.

A number of aid societies have been established at the cost of the large prison, which admit prisoners on release who have been discharged and well employed in confinement. Work is forced, work and instruction given, as in England. It is interesting to note that the first aid society was founded at Copenhagen in 1851 through the exertions of Miss Fry. Besides the regular prison, there are three reformatories for juveniles modelled on the French school at Mettray; they have been founded by private benevolence, but receive aid from the state. Agriculture is the principal employment of the inmates.

*France.*—Prisons and their management have not attracted close or continuous attention in France. Dysentery, cholera, war, revolutions, and internal troubles may be pleaded as the excuse. A system based on the principle of individual segregation as practiced in the United States was on the point of being adopted in France when the legislation to secure it was interrupted by the revolution of 1848. Under the empire the question was generally understood to be more pressing political than penal. Cellular imprisonment was, however, adopted partially, but only on a limited extent, for penitentiary and central prisons in which the prisoners lived and worked in association had been established early in the century, and their use was extended. They survived all unharmed in the darkest years. The long-term convicts went to the *bagne*, the great convict prisons at the arsenals of Rochefort, Brex, and Toulon; and in 1851, a few years after it had been abolished by England, transportation

to penal colonies was adopted by France. In 1856 Napoleon III. appointed a commission to inquire and report upon the whole question, but its labors were early interrupted by the Franco-German War. Three years later a fresh commission, appointed by the national assembly to discuss parliamentary reform, made a most exhaustive report in 1859. It unhesitatingly recommended cellular confinement, and the principle became law the following year. This system of prison discipline then became applicable to all persons awaiting trial, to those sentenced to any term up to a year and a day, and to those for longer terms provided they asked to be kept separate and apart. It was calculated by the commission first mentioned that there were nearly eight thousand cells already in existence and available, but an additional twenty-two thousand would have to be constructed at an outlay of sixty-three millions of francs in order to meet the demands of this new system. A model cell was designed and plans for model prisons, but the expense the change would entail appears to have deterred French authorities, both the central executive and the *arrondissement* *governors*, from promptly making it. There are not more than ten, or a dozen cellular prisons in France, and two of them are in Paris—Mazas (for trial prisoners) and La Santé, but the latter is not entirely cellular. The construction of others has been contemplated, but in few cases proceeded with, and many years will probably elapse before any uniformity in penal treatment is established in France.

Prison administration is complex in France, and there are many kinds of prisons,—a few of them being under the authority of the minister of the interior—(1) the *maison d'arrêt*, temporary place of detainer in every arrondissement for persons charged with offences, and those sentenced to more than a year's imprisonment who are awaiting transfer to a *maison centrale*; (2) the *maison de justice*, often part and parcel of the former, but only existing in the arrondissement towns for the safe custody of those tried or sentenced at the assizes; (3) the dépôt situated on the bank of the Seine, for all sentenced to various forms awaiting deportation to New Caledonia (Arles) or sentenced rail to Arles, their removal to French Guiana; (4) departmental prisons of various dimensions, for temporary confinement, or those sentenced to less than a year, or, if provided with sufficient cells, those sentenced to separate confinement; (5) the *maisons centrales*, or central prisons, for all sentenced to more than a year, or for men and women above sixty sentenced to *travaux forcés*; (6) *maisons de force*, for women sentenced to *travaux forcés*, or both sexes sentenced to reclusion; (7) prisons for those sentenced to simple detention; (8) penal settlements in Corsica, more particularly at Ajaccio, Bastia, and Corte, where the regime of night is the same as in the *maisons centrales*; (9) military establishments for juvenile offenders; and (10) *dépôts de force* for prisoners who are travelling, at places where there are no other prisons. The total number of prisons of all classes in France, exclusive of the last, exceeds 500, and the prison population averages 10,000 daily. Besides the foregoing there are a certain number of military prisons, under the military command at the great garrison towns, or in Algeria; and at all the garrisons there are military prisons for soldiers or sailors who have broken laws civil or military. The latter are under the authority of marine, who also has special charges of the penal establishment a distance from France, including French Guiana and New Caledonia, where there are several prisons and hospitals for the confinement of natives. The disciplinary treatment of all prisoners in separate confinement is much the same in France as elsewhere; the isolation while it lasts is complete and is broken only by the frequent visits of officials. The exercise is solitary, and at daybreak the same rule obtains by each prisoner occupying a separate box, or by having service in the centre of the prison, in which all the cells, doors, windows open, or are open. It may be stated here that religious observance prevails everywhere; and prisoners at French Colonies may receive the ministrations of members of their own creed. Female prisons are mostly managed by nuns or members of the female religious orders. There is one at Brussels especially kept for Protestant female prisoners, and managed by a Protestant sisterhood. The rules of association in the separate prisons are dissimilar by classification, so far as it goes. But prisoners are at least kept in exception: trial prisoners are together; those for a year are kept apart from the ordinary convicts, and *ouvriers en règle* for the benefit of all the men. Male and female occupy different prisons. In almost all prisons there are at least a few separate cells, these are utilized either for the recidivists and those of worse character, or for any well-behaved prisoners who exhibit a real desire to amend. The diet, although coarse, is liberal. It may be supplemented by purchases made from the market, at which both wine and tobacco may be obtained by all who can pay for it. Each prisoner may also spend a certain proportion of his earnings or *pécule*, the rest being saved for his discharge. What remains of the profits of the prisoner's labour is handed over to the contractor, who also receives a grant per prisoner from the state. Labour is only obligatory upon those so sentenced; it is purely industrial; penal labour, such as *travail forcé* or *crucé*, does not exist in French prisons. In the smaller it is not easy to find comparison for the inmates, but in the

larger many and various industries are carried on. Among the more ordinary trades the manufacture of "articles de Paris," toys, neat bonbon boxes, hosiery, and cabinet-making produce good financial returns. The labour of the prisoners in Corsican settlements has been usefully directed upon the reclamation of marshy lands, the clearing of forests, and the tilling of the less fertile districts. The agricultural results have been good as regards the cultivation of the orange, olive, and vine; mulberry trees have been planted for the silk-worm, and the wheat fields have returned rich harvests of grain, much esteemed in Italy and the south of France. Good roads and many canals have been made, to open up the interior. These Corsican prisons have long suffered from the unhealthiness of their neighbourhood, but the draining of the marshes, the development of irrigation, and the plantation of trees have all combined to improve their sanitary conditions.

The efforts made in France, more particularly by private benevolence, to cope with juvenile delinquency have been very praiseworthy. French reformatories are of two classes—those that are punitive or correctional, and those that are simply reformatory. To the first, where the discipline is severe, are sent all youths convicted of offences committed with full knowledge of their criminality, and these relegated from the reformatories as insubordinate; to the second, children proved guilty but not responsible for their acts, or the ill-conducted whose parents cannot manage them. The first-named are public institutions maintained by the state; the latter are private, and may be supported entirely by subscriptions. There are in all thirty-eight of the former, as well as five penal colonies, and five juvenile quarters attached to various departmental prisons; of the latter there are twenty-eight. All these are for males. For females there are twenty-three private establishments and one public. The most important of the public reformatories for boys is that of La Petite Roquette in Paris, immediately opposite the convict prison of the same name, in front of which executions are carried out. Of the private institutions that of Mettray near Tours, started by the benevolent enterprise of M. de Metz, has a world-wide reputation. A very successful female reformatory is that of Darnétal near Rouen, where the women are employed in farming and field operations.

As regards the most heinous offenders, France not only clings to deportation, but is disposed to enlarge and multiply her penal settlements. In 1884 the Government had under consideration the necessity for sending out all "recidivists" to the Polynesian islands. This, however, has been hindered for the moment by the energetic protest of the Australian colonies, and, instead of the number sent to New Caledonia being increased, French Guiana will probably be more largely utilized. In the former islands most of the evils which attended the early days of transportation to Australia have been apparent. The French convicts either remain in the hands of the Government incarcerated in badly constructed prisons, where discipline and supervision are unsatisfactory or incomplete, or they pass into a state of semi-freedom to work for free settlers on their own account. There are not enough of the latter to afford much employment, and the conditions of the soil of New Caledonia are not such as to encourage the convicts to work for themselves. It is extremely improbable that the penal settlement will ever grow into a prosperous self-supporting colony, and thus the chief end of deportation remains unachieved. At present the French penal settlements beyond sea are merely badly-built indifferently-managed prisons at a long distance from home.

*Germany.*—There is a similarity in the prison discipline of the various units of the German empire. In the grand-duchy of *Baden* there are four kinds of prisons—district prisons, fortresses, houses of correction, and central prisons. The punishment in the two first named is simply detention or privation of liberty,—the district prisons being for persons under examination and waiting trial, or those sentenced to less than six weeks' imprisonment. Sentences above that time are endured in the central prisons. The principle of cellular imprisonment is the general rule, but it is not extended, unless at a prisoner's wish, beyond three years. For youths between twelve and eighteen the limit is six months. Prisoners unfit for solitary confinement and those who have endured three years' detention are kept together, but they are not associated during working hours. Both systems are supposed to be attended with good results in *Baden*. Both have their merits, but popular feeling inclines most to the cellular plan as conducing to reform while it keeps the prisoners from mutual contamination. The chief cellular prison is at *Bruchsal*, where there is accommodation for five hundred, but there are a certain number of separate cells attached to many other prisons. The labour in the prisons is industrial as opposed to penal; contractors are not encouraged; and in most prisons the administration itself keeps the employment of the prison in its own hands. Forty per cent. of the prisoners on admission are ignorant of any trade, but they do not leave prison without learning one. Prisoners' aid societies exist in twenty-nine out of fifty-nine districts, and they achieve good results, although their aid is not too frequently invoked.

The bulk of the prisons in *Batavia*, mostly converted castles and convents, are on the collective system, but there are four cellular prisons—one at *Nuremberg*, and three other district prisons for those awaiting trial. The prisons are much the same as in *Baden*. There are police prisons for first arrests; district prisons mentioned above, which also take short sentences; prisons for three months' sentences and upwards, and for juveniles; and houses of correction. There are also special prisons set apart for persons convicted of theft, fraud, robbery, receiving, whose sentences exceed three months; and a system of classification exists which separates all likely by their previous character to exercise a baneful influence on their fellows. For the long-term prisoners the labour may be upon public works beyond the walls of the jail, and prisoners may demand to be so employed, or in work for which they are fit. Industry and good conduct will secure a remission of sentence. After three months of the sentence have been served there is no purely penal labour. Industrial labour is conducted by the prison authorities, who are not in favour of the employment of contractors, which is thought to jeopardize discipline. Secular education is not overlooked; there are hospitals, chapels, libraries, and the administration generally is humane. There are numerous societies to assist discharged prisoners, which, however, are said to be much hampered in action by the ignorance and prejudice of the public. One at *Munich* has nevertheless done great good.

There are but few prisons in *Prussia* in which isolation is exclusively carried out. But in forty-six cellular and associated imprisonment exist side by side; the total number of cells is, however, small when compared with the total population in prison. The advantage of introducing the system of "progressive stages," of passing from strict separation to labour in association, is anxiously discussed, but nothing yet has been done. Prussian prisons may be classed as—(1) those exclusively for hard labour, (2) those for imprisonment and simple detention, and (3) those of a mixed character. Hard-labour sentences may be for any term from one year to life; the labour is compulsory, without restriction, both inside and beyond the walls. The maximum of simple imprisonment or detention is for five years, during which time a prisoner is not compelled to work except in accordance with his capacity and the position he occupied in social life; nor need he work outside the prison against his will. Imprisonment in a fortress, which may be for life and the minimum of which is for one day, means simple deprivation of liberty. There is also a detention on summary conviction for vagrants and beggars limited to six weeks. These may be made to work inside or outside the prison. There is no penal labour; but much variety and enterprise exist as regards the prison industrial employments, which, in addition to the ordinary kinds, include feather-scraping, leather-dressing, turning, carving, illuminating, &c. The males also spin; the women make gloves, cigars, and tapestry, embroider, knit, weave, and spin. The work is carried on through contractors, who pay a certain sum on the amount produced. A portion of their earnings goes to the prisoners,—half of it to be expended in buying extra food, half accumulated against release. To reduce evils of association it is ordered that first sentences shall be separated from hardened offenders, but this classification is not always possible; juvenile prisoners are, however, kept apart in cells. Release, provisionally, may take place after three-fourths of the sentence has been endured with good conduct, but the licence to be abroad may be revoked for a breach of law. There are many prisoners' aid societies, the best being in *Rhenish Prussia* and *Westphalia*, but the results obtained have not been very satisfactory. Employers and free workmen will not receive liberated prisoners freely, and the aid societies would effect more if they were more centralized and worked more together. Prussian prisons are on the whole well organized; the discipline is severe yet just; order reigns everywhere; secular instruction and religious ministrations are ample, and the employment of prisoners according to their capacities is carefully attended to. But many of the prisons require rebuilding or reconstruction; isolation at night should be the universal rule; and more cells are needed to ensure the separation of the trial prisoners and short sentences. Administrative centralization is much needed in *Prussia*.

Prison discipline has attracted close attention in the kingdom of *Saxony* since 1850, when the penitentiary at *Zwickau* was first opened and conducted with satisfactory results. In 1854 it was decreed that all Saxon prisons should follow the same system, which is that of treatment either solitary or associated according to individual wants; neither rule obtains exclusively, and the prisons have facilities for both. Work, education, and diet are supposed to be carefully allotted to prisoners. The prisons follow the usual classification of German prisons; there are those for severe punishment, two in number, three for less severe punishment, and two for the older offenders. Besides these there are the fortresses and the prisons of detention. The labour is purely industrial, not penal; *Saxony* is a very industrial country, and its prisons produce nearly every article of manufacture. Work is carried out in them partly by contractors and partly by the authorities. In the five reformatories agriculture is the principal

(5) the amendment prisons or houses of industry established by the empress Catherine. These are all on the associated system, and fall very far short of accepted ideas on prison management. But an entirely new cellular prison has recently been erected in St Petersburg, which is a model of its kind. It is a house of detention for persons awaiting trial, and contains upwards of a hundred cells. All the internal arrangements of this prison are excellent; but it may be doubted whether the Russian Government will embark upon the expenditure necessary to build others of the class. The emancipation of the serfs in 1867, followed by the substitution of imprisonment for corporal punishment, added enormously to the prison population of Russia. A great increase of prison accommodation became necessary, and a commission was appointed to frame a new penitentiary system. This, as now adopted, although not entirely carried out, consists of two parts—punitive imprisonment for short sentences, and penal probationary detention as a preliminary to banishment to a colony. For the first, central prisons, associated not cellular, are being constructed at various points, and a regulated system of labour will be introduced following the lines of that in force in other European countries. For the second, at the end of the probationary period banishment, or, as it is styled in official language, enforced colonization, will be the rule.

Deportation to Siberia began in 1591. It was principally used for political prisoners, insurgents, religious dissenters, and conspirators. Large numbers of Poles were exiled in 1758; others again in 1830, and now, since the Nihilist movement, numbers of these implacable foes to the existing régime are regularly despatched to Siberia. The total number deported varies from 17,000 to 20,000 per annum, but this includes wives and children who may elect to accompany the exiles. The sentences are of two kinds—(1) the loss of all rights and (2) the loss of particular rights. The first includes degradation, the rupture of the marriage tie, inability to sign legal documents, to hold property, or to give a bond. The exile must wear prison dress, and have his head half-shaved. He may be flogged, and if murdered would not be much missed. After a lengthened period of probation in prison the exile becomes a colonist and may work on his own account. Those sentenced to the loss of particular rights are only compelled to live in Siberia, where they may get their living as they can. Many, however, are condemned to spend a portion of their time in confinement but without hard labour. The exiles are sent from all parts of the empire by rail or river to Ekaterinburg, and thence to Tiumen, whence they are distributed through Siberia. Those deprived of partial rights are generally located in western Siberia. Those deprived of all rights go on to eastern Siberia. The latter go by river generally to Tomsk; thence they walk to their ultimate resting place, which may be Irkutsk or Yakutsk or Tchita, or the island of Saghalien, and the journey may occupy months. Not long ago a party of convicts was despatched by sea to the last-named destination, embarking at Odessa and travelling through the Suez Canal and by the Pacific Ocean. There are several hundred prisons in Siberia. They are of three kinds:—(1) the *etape*, which afford temporary lodgings for prisoners on the line of march; (2) the *prisylnie*, where the detention is often for several months during the winter or until the ice is broken up; and (3) the *ostrog*, the generic Russian name for a prison, which is the place of duranco for all exiles not on their own resources. Few of the large prisons in Siberia were built for the purpose. They are converted buildings—old factories, distilleries, and so forth. They are all upon the associate principle, containing a number of large rooms to accommodate any number from twenty-five to a hundred. The great central prison near Irkutsk, called the Alexandrfsky, one of the most important in Siberia, generally holds from 1600 to 2000 prisoners all under sentence of hard labour, and awaiting transfer to the mines. Dr Lansdell, who visited this prison in 1879, found the prisoners very short of work. Some were engaged in making cigarette papers, others in shoemaking and brickmaking. The prison is a huge stone-built building, very different from the ordinary run of Siberian prisons, which are usually built of logs canked with moss to keep out the cold. They are surrounded by a high wooden palisade. Each prison has its hospital, chapel, generally a schoolroom, and a few workshops. The prisoners themselves are not unkindly treated. At most of the stations there are local committees to watch over the welfare of the prisoners. This is an extension of the Imperial Society of St Petersburg already mentioned. The committees supply books and visit the prisoners. They clothe and educate the prisoners' children, and help their wives to employment. They also augment the prisoners' diet from funds obtained by subscription. The regulation rations of Siberian exiles seem very liberal. The Russian prisoner has nearly twice the amount of solid food that an English prisoner receives, and he is at liberty to add to his diet out of his own means, which the English prisoner is not. The prisoners are also supplied with ample clothing if they have none of their own, those sentenced to deprivation of all rights being obliged to wear convict dress. The discipline of the prisons is now in accordance with European ideas. Prison offences are punished by relegation to a solitary cell, a certain number of

which exist at all the prisons. Diminutions of diet are also inflicted, and an obligation to wear irons if they are not already worn. All exiles wear leg-irons for a certain time. These are riveted on to the ankles, and caught by a chain which is carried suspended to a belt round the waist. The irons are worn for various periods from eighteen months to four and even eight years. Very heinous offenders or those who have escaped frequently are chained to a wheelbarrow, which they are obliged to pull about with them wherever they go. A more severe punishment when confinement and irons fail is birching with a rod, for the knout is now abolished. The rod consists of switches so small that three may be passed together into the muzzle of a musket. The punishment is described as not more severe than that inflicted at English public schools. There is another flagellator, however, called the *pleta*, a whip of twisted hide, which is still retained at a few of the most distant Siberian prisons and only for the most incorrigible, on whom irons, the birch, and other punishments have had no effect. The costliness of deportation is enormous and the results it obtains doubtful. The slow colonization of this vast territory may follow eventually, but there are already great difficulties in finding employment for the mass of labour in the Government's hands. The mines of gold, silver, and coal are passing into private hands, and there are no other public works. Hence part of the Russian criminals who would have gone to Siberia are detained in the large prisons in Russia, where they are employed in manufactories or in the labours of ordinary mechanics, or any outdoor work such as making bricks, mending roads, and manufacturing salt. Nevertheless recent visitors to Russian prisons, whether in Russia proper or in the heart of Siberia, describe the prisoners as generally idle. The principle of progressive stages by which a prisoner can gain a remission of sentence or milder treatment prevails throughout. The well-conducted persons can earn wages, and may spend the money in buying an increase to their diet. The bulk of the worst convicts gravitate to the island of Saghalien, where the number in 1879 was about 2600. Half of those were kept in prison, half remained comparatively free. The discipline here is very severe. The diet is said to be scanty, and as the island is barren everything has to be imported. Fish, however, is found in large quantities. There are four large prisons at Dui, the principal post on the island, which are insufficiently heated in winter and generally overcrowded. The convicts are chiefly employed in raising coal from mines which are let to a company. Very conflicting evidence is current as regards the Siberian prisons. Prince Kropotkin, an exile, speaking with some authority, denounces them as hotbeds of vice and cruelty. Dr Lansdell on the other hand, a reputable eyewitness, does not on the whole speak unfavourably of them. He describes them as rough, perhaps; but so are Siberian dwellings. He thinks that as compared with the English convict the Siberian is not badly off. The labour is lighter; he has more privileges; friends may see him oftener and bring him food; and he passes his time neither in the seclusion of a cell nor in unbroken silence, but among his fellows with whom he may lounge, talk, and speak. The Russian convict, however, misses those intellectual, moral, and religious influences which are abundantly showered upon the English. There are no prisoners' aid societies in Siberia, and the convict, after release, when suffered to begin life again on his own account, carries with him always the convict stain and is hindered rather than helped to begin life afresh. Dr Lansdell sums up his opinion in these words:—

"Taken at the worst, condemnation to the mines is not so bad as it seems; and, in the case of peasant exiles willing to work, I cannot but think that many of them have a better chance of doing well in several parts of Siberia than at home in some parts of Russia. There is reason to suppose that reports of the ill-treatment of Russian prisoners have been greatly exaggerated by careless, ill-informed, or malicious writers. No doubt some years ago there were good grounds for serious complaint. It is very evident that now the political prisoner, beyond exile, and temporary confinement in the jail, is not ill-used. He is not always subjected to the ordinary discipline of the criminal convict, nor is he obliged to associate with them. A fabulous story has long been current that the worst criminals were buried alive in quicksilver mines, where they were speedily killed by the unhealthy fumes. There are no quicksilver mines in Siberia, and the principal mines, those of Nertchinsk, are now passing out of Government hands. These are mostly of silver, although other minerals and gems are found in the neighbourhood. The hours of labour in the Nertchinsk mines were thirteen, and it was the same at the Kara gold mines. The convicts arrange their hours of work themselves. No definite amount of mineral was required, so they might work hard or not as they pleased. No doubt the lot of convicts in these mines was hard. Besides the laxity of discipline, the herding together of the worst characters and the deprivation of social, intellectual, and religious privileges must have made life a burden to many."

Spain, like Portugal, still lags behind. It is not to the credit of a country in which prison discipline was discussed three centuries ago that now at the close of the 19th its prison system is about the worst in Europe. Till very recently the posts of governors in the jails were sold to the highest bidder, and purchasers were suffered to recoup themselves out of the unfortunate wretches committed to their charge. The principal prison in the capital of the kingdom was nothing more than a converted slaughter house where pigs were killed and salted, as its name, the *Saladero*, implied. This dark, dirty, noisome den, although generally condemned, continues to serve even now. Numerous efforts to provide a more suitable prison have been made from time to time. The

construction of model prisons was decreed as far back as 1847, but in 1860 nothing had been done, and a new project was brought forward. Again in 1860 a fresh scheme replaced the previous ones, which were still dead letters. Seven more years elapsed, and in 1876 a new law was passed providing for the construction of a new cellular prison in Madrid with cells for a thousand prisoners. This law too hung fire, and the prison is not yet completed. The bulk of the prison population in Spain is still sent to *presidios*, or convict establishments, where general association both in the prison and at labour is the rule. The principal of these are situated at Cartagena, Valencia, where there are two prisons, Valladolid, Granada, and Burgos. There are also prisons at Alcalá, Tarragona, Saragossa, and Santoña. Persons convicted of grave crimes are deported to the Balearic Islands or to the penal settlements in Africa, the principal of which are situated at Ceuta and Melilla. Throughout these establishments there is an utter absence of sanitary regulations; the diet is coarse and meagre; the discipline is brutal; the authorities are quite callous; and morality does not exist. The Spanish authorities, however, claim the credit of having abolished corporal punishment in their prisons.

*Sweden.*—A great impetus was given to prison reform in Sweden by the interest taken in the question by King Oscar I. in 1840. Following special legislation, thirty-eight new cellular prisons were built in the various provinces of the kingdom. These prisons have been used since for all prisoners awaiting trial, those condemned to reclusion and those sentenced to imprisonment with hard labour for two years and under. Persons sentenced to pay fines, but unable to pay, go to the cellular prisons. The isolation is continuous day and night. Besides these cellular there are a number of associated prisons for terms longer than two years and up to life. The labour in the first-mentioned is of the usual kind—tailoring, shoemaking, and some kinds of carpentry. Trade instructors are specially appointed, so as to provide a prisoner on liberation with some employment. In the associated prisons there is more variety of work: linen and woollen cloths are manufactured, timber split up for matches, granite cut and dressed for buildings and pavements. The female prisoners weave textile fabrics, and make match boxes. A portion of the earnings is granted to prisoners, who, to a limited extent, may be spent in buying extra food. There is no purely penal labour, nor any regulated system of granting remissions for industry or good conduct. Many aid societies were formed about twenty-five years ago, but through want of success or funds their number has dwindled down to two.

*Switzerland.*—From the complete independence of each canton, each has its own special penal system and places of imprisonment. Hence the systems are various, and are not all equally good. The prisons of Switzerland may be divided into four groups:—(1) those of the cantons of Uri, Schwyz, Unterwalden, and Valais, which are still of a patriarchal character; (2) those of Fribourg, Basel (rural), and Lucerne, which are on the associated plan and unsatisfactory from every point of view; (3) those of the cantons of St. Gall, Vaud, Geneva, and Zurich, which have prisons for associated labour and separation at night, while Soleure, Grisons, Bern, and Schaffhausen are labouring to raise their prisons to this level; (4) the penitentiaries of Lenzburg, Basel (urban), Neuchâtel, and Tirino, which are good modern prisons in which the cellular system is completely applied. The system is one of progression, the prisoner passes through several stages of isolation, employment in association, and comparative freedom; but only at Neuchâtel is there separation by day as well as night. The general principle is one of collective imprisonment; but there is an attempt at classification, according to degrees of morality, in the best prisons. Sentences may be either to imprisonment or reclusion with hard labour. The first may be from twenty-four hours to five years; the second from one year to fifteen, twenty, thirty years, or to life. An abbreviation of punishment may under all the cantonal laws be obtained, but such reduction is rarely made according to fixed rules. In most of the cantons prisoners have a share in their own labour. This labour is chiefly industrial, but there is a form of penal labour to be seen where the plan has survived of employing certain prisoners to sweep the streets, make roads, or dyke the rivers. Such labour is felt to have a bad moral effect, and industrial labour is preferred. The latter is conducted by the administration itself, and not by contractors. It is thought that the state can introduce a greater variety of employments, and control the prisoner better when at labour than could free employers. Aid societies exist in most of the cantons; the first was established at St. Gall about 1845. Wherever they exist the societies protect prisoners in duance and assist prisoners on release by providing tools and employment with private persons. The only drawback in the Swiss aid societies is the want of organization and uniformity of action.

*United States.*—There is no uniform prison system in the United States. The variety of jurisdictions following the constant extension of territory and development of communities more or less populous perpetuates changing conditions, and the supreme Government has not concerned itself greatly with prison affairs, and has claimed no supervision or special control. The rule of local self-

government has left each jurisdiction to manage its prison according to its own ideas, and hence the utmost diversity of practice still obtains. While some prisons are as good as need be, others are marked with many defects. There is a wide distinction between the best and the worst. In the country which initiated prison reform, numbers of prisons exist nowadays which fall far below the commonest requirements of a good prison system. Taken broadly, the prisons of the Union may be classed into—(1) State prisons; (2) district prisons; (3) county prisons; (4) municipal or city prisons. Each State as a rule has its own State prison, but Pennsylvania and Indiana have two and New York three such prisons. The cellular system, or the rule of continuous separation, to which reference has been made already (see p. 753), was at first followed by several States, but gradually abandoned in favour of the so-called silent system, or that of labour in association under the rule of silence, with cellular separation at night. At the present time there is but one prison, the Eastern Penitentiary of Philadelphia, managed on the purely solitary plan. Of the long-sentenced convicts 96 per cent. are now confined in congregate prisons. There are about forty State prisons in all. Of the district prisons intermediate between the State and the county prisons there are but few. The county prisons are by far the most numerous. The county in the United States is the unit of political organization under the State, and, with area and population comparatively limited, is a convenient subdivision for the purposes of the criminal law. Hence it has been asserted that no one knows exactly the number of county prisons in the United States, but it has been computed at upwards of two thousand. The city or municipal prisons are also very numerous and constantly increasing. Each and every one, as in the State prisons, is managed locally by local authorities, with the inevitable result of the utmost diversity in practice, and often enough the utmost neglect of the commonest rules of prison discipline. A self-constituted body inspected a couple of hundred of these jails a few years back, and reported that they were mostly defective from a sanitary point of view, insecure, and so constructed as to compel the promiscuous association of all classes old and young, the guilty and innocent, the novice and the hardened in crime. The sexes even were not invariably separated. Little or no employment was provided for the prisoners, and in few prisons was any effort made to compass religious or intellectual culture. An eye-witness, Dr. Wines, reporting of other jails of the same class still more recently, unhesitatingly condemned them. "Ohio, to-day," says the Ohio Board of Charity, "supports base seminaries of crime at public expense." "In our jail system lingers more barbarism than in all our other State institutions together." Yet there are a few and conspicuous exceptions to the general verdict of condemnation. The discipline and management of the district prisons at Albany, Detroit, Rochester, and Pittsburgh are excellent. The good example is gradually becoming more and more largely imitated. Where good prisons exist it will be found that their administration remains for some length of time in intelligent hands, free from the pernicious influence of partisan politics. The chief drawback to improvement is the uncertainty no less than the complexity of the governing bodies. These are apt to be changed capriciously; and, what is worse, they are needlessly intricate and often far too numerous. They act independently, without reference to each other, and they are not too ready to benefit by example and experience. What is wanted is a supreme central authority over all the prisons of a State, if not throughout the Union. Wherever there is the nearest approach to this the results are most satisfactory.

It is not strange that under these conditions discipline should also vary greatly, or, as has been said, "every variety of discipline, lack of discipline, or abuse of discipline is found." Neither the deterrent nor the reformatory agencies are properly or uniformly brought to bear. Prison punishments are still severe; although flogging is nominally abolished, it is said to be still practised in prisons where it is forbidden; and some more ancient methods such as the yoke, the shower bath, and the iron crown have not yet entirely disappeared. There is, however, often good secular and religious instruction. The dietaries are fuller than on the opposite side of the Atlantic, meat is a more common ingredient, and Indian meal is very largely used. The financial results obtained are not unsatisfactory: many of the State prisons are now self-supporting, and an examination of the labour returns will prove that much enterprise has been displayed in finding employment for the prisoners. There is no purely penal labour, although much of the labour performed is sufficiently severe. There may be no treadmill or cranks, but convicts in Alabama and Texas have been employed to build railways; they have raised cotton in Mississippi, and have worked mines in Tennessee and New York, while in many States they are utilized in gardening and agriculture. A great deal of labour has been expended on quarrying and dressing stone for building, or for burning into quicklime; at Auburn there is a large manufactory of agricultural tools; Ohio employs saddlers; Massachusetts prisoners make ornamental iron work; in Michigan they tan leather; and at Dannemora, in northern New York, iron ore is quarried, smelted, forged, and wrought into nails by the prisoners.

In general the labour is hired by contractors at a fixed sum per day, which varies from a few cents to as much as a dollar. The chief cause for the present inadequacy of the American prisons, over and above the faults in administration already mentioned, is probably the rapidly increased demand on their accommodation in recent years. This is due partly to the growth of population, partly also to the influx of "coloured" criminals since the emancipation. In the days of slavery the slave was punished summarily by his master, but now he is arraigned and sent to prison. The result has been that the prisons were suddenly crowded before any new and improved system could be introduced.

While there are but few agencies for the assistance of discharged prisoners, considerable care is devoted in the United States to the treatment and checking of juvenile crime. Reformatories have existed since 1825, when the first was established on Randall's Island within the limits of the city of New York. Others followed; but these did not form part of the penal system of the States till 1847, when the State reform school at Westborough was established by law. They soon increased and multiplied, and now between sixteen and twenty are to be found within the principal States. There are also a number of semi-public schools. The average reformatory population is about 15,000. The results are said to be very satisfactory. The percentage of youths reformed and trained into good citizens has been placed as high as 60, 75, even 80 per cent. Parents may in some States contribute to the support of their children in reformatories, but as a rule the inmates are orphans or abandoned children or those whose parents are very poor. The best system for training and caring for juvenile offenders probably is that which obtains in Massachusetts. (A. G.)

**PRISREND, PRISDREN, PRISDRA, PRISREN, or PRISRA**, in Roumelia, the chief town of a sandjak and the seat of a Greek and a Roman Catholic archbishop, in the Turkish vilayet of Kossovo (formerly Monastir), stretches for 2 or 3 miles along the north-western base of the Scardus or Shar-dagh, and is traversed by the rapid waters of the Resna Mitritza, which, issuing from a deep gorge a little above the town, joins the Drin (White or Albanian Drin) a few miles below. To the north-north-west of Prisrend, which lies at a height of 1577 feet above the sea, a great undulating and fertile plain extends for more than 40 miles towards Ipek. In 1865 the Roman Catholic archbishop estimated the total at 50,000 (8000 Mohammedan families, 3000 Greek, and 150 Latin). It is now about 46,000. There is a castle on the buttress of the Scardus, at the foot of which lies the Christian quarter, with a small brick-built ancient-looking Byzantine church. The old cathedral, now a mosque, is also a Byzantine building. Prisrend, doubtfully identified with Tharendus, was at one time the capital of Servia, and the district is still called Old Servia. At present the town owes much of its importance to its manufacture of arms; and it also produces glass, pottery, and saddlery.

**PRIVATEER** is an armed vessel belonging to a private owner, the subject of a belligerent power, commissioned by the sovereign of that power. The commission is either a commission of war or of marque and reprisals in time of peace. It was marque in this sense which was granted to aggrieved subjects of the realm of England as early as the statute 4 Hen. V. c. 7. The term "letters of marque," however, is now generally applied less strictly to the commission under which a privateer sails in time of war. The acceptance of a commission from a belligerent power by a neutral, though not piracy by the law of nations, has frequently been made so by treaty.<sup>1</sup> Acceptance of such a commission by a British subject is forbidden by the Foreign Enlistment Act, 1870. A vessel with a commission from each of two powers at war with one another is a pirate by the law of nations. Privateers stand in a position between that of a public ship of war and a merchant vessel. They are not entitled to the full rights which the comity of nations extends to public ships of war; e.g., by the municipal regulations of most nations they may not carry the flag of a public ship of war. A

capture made by a privateer may either become the property of the captor or, following the general rule of international law, the property of the state (see **PRIZE**). In Great Britain, in order to encourage privateering, the prize taken by a privateer was formerly divided between the owners and the captors, and the rights of the crown were specially excluded in numerous Prize Acts. But now, by the Naval Prize Act, 1864, a prize made by a privateer belongs to the crown in its office of admiralty. By the United States Prize Act of 1864, the whole proceeds of a prize made by a privateer go, unless it is otherwise provided in her commission, to the captors. The sum awarded is divided, in the absence of agreement, equally between the owners and the ship's company.

Privateering is now a matter of much less importance than it formerly was, owing to the terms of Art. 1 of the Declaration of Paris, April 16, 1856, "Privateering is and remains abolished." The Declaration binds only the powers who are signatories or who afterwards assented, and those only when engaged in war with one another. The United States, Mexico, Uruguay, and Spain have not acceded to it, and thus it would not hold in case of a war between the United States and any other power, whether the latter were bound by the Declaration or not. By the constitution of the United States, Congress has power to grant letters of marque and reprisal. Congress, by an Act of March 3, 1863, authorized the issue of letters of marque by the president, but they were never in fact issued either by the United States or Confederate Government.

In the Franco-Prussian War of 1870, Prussia, in spite of the Declaration of Paris, took a course very little removed from privateering in the creation of a volunteer fleet.

**PRIVET** (*Ligustrum*), the vernacular name<sup>2</sup> of a genus of *Oleaceæ*. There are several species, all of them shrubs or low trees with evergreen or nearly evergreen opposite entire leaves, and dense cymes of small white tubular four-parted flowers, enclosing two stamens and succeeded by small, globular, usually black berries, each with a single pendulous seed. The best-known species is the common European privet, which makes good hedges in cases where no great powers of resistance to the inroads of cattle, &c., are required. *L. ovalifolium* thrives by the seaside and even in towns, and is thus a valuable all but evergreen shrub. *L. lucidum* is taller and handsomer. There are several other species, mostly natives of China and Japan, some of which when attacked by a species of scale-insect (*Coccus*) yield a waxy substance.

**PRIVILEGE**, in law, is an immunity or exemption conferred by special grant in derogation of common right. The term is derived from *privilegium*, a law specially passed in favour of or against a particular person. In Roman law the latter sense was the more common; in modern law the word bears only the former sense. Privilege in English law is either *personal* or *real*,—that is to say, it is granted to a person, as a peer, or to a place, as a university. The most important instances at present existing in England are the privilege of parliament (see **PARLIAMENT**), the privilege which protects certain communications from being regarded as libellous (see **LIBEL**), and certain privileges enjoyed by the clergy and others, by which they are to some extent exempt from public duties, such as serving on juries. Privileged copyholds are those held by the custom of the manor and not by the will of the lord. There are certain debts in England, Scotland, and the United States which are said to be privileged, that is, such debts as the executor may pay before all others—for example, funeral expenses or servants' wages. In English law the term "preferred" rather than "privileged" is generally applied to such debts. There are certain deeds and summonses which are privileged in Scotch law, the former because they require less solemnity than ordinary deeds, the latter because the ordinary

<sup>1</sup> Instances will be found in Phillimore, *International Law*, vol. i. pt. iii. ch. xx.; Twiss, *Law of Nations*, vol. ii. ch. x.

<sup>2</sup> Another form of the name, *primprivet*, *primprint*, or *primet*, like *ligustrum* itself, used at one time to be applied to the primrose.

*inducia* are shortened in their case (see Watson, *Law Dict.*, s.v. "Privilege").

In the United States the term privilege is of considerable political importance. By Art. IV. § 2 of the constitution, "the citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." By Art. XIV. § 1 of the amendments to the constitution (enacted July 28, 1868), "no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States." It will be noticed that Art. IV. applies to citizens of the States, Art. XIV. to citizens of the United States. "The intention of this clause (Art. IV.) was to confer on the citizens of each State, if one may so say, a general citizenship, and to communicate all the privileges and immunities which the citizens of the same State would have been entitled to under the like circumstances" (Story, *Constitution of the United States*, § 1898). The clauses have several times been the subject of judicial decision in the supreme court. Their practical effect may be thus illustrated. With regard to Art. IV., it was held that a State licence tax discriminating against commodities the production of other States was void as abridging the privileges and immunities of the citizens of such other States (Ward v. State of Maryland, 12 Wallace's Reports, 418). With regard to Art. XIV. 1, it was held that its main purpose was to protect from the hostile legislation of the States the privileges and immunities of citizens of the United States, looking more especially to the then recent admission of negroes to political rights. Accordingly it was held that a grant of exclusive right or privilege of maintaining slaughter-houses for twenty-one years, imposing at the same time the duty of providing ample conveniences, was not unconstitutional, as it was only a police regulation for the health of the people (The Slaughter-House Cases, 16 Wallace, 36). The same has been held of a refusal by a State to grant to a woman a licence to practise law (Bradwell v. The State, 16 Wallace, 130), of a State law confining the right of suffrage to males (Minor v. Happersett, 21 Wallace, 162), and of a State law regulating the sale of intoxicating liquors (Bartemeyer v. Iowa, 18 Wallace, 129). Suits to redress the deprivation of privilege secured by the constitution of the United States must be brought in a United States court. It is a crime to conspire to prevent the free exercise and enjoyment of any privilege, or to conspire to deprive any person of equal privileges and immunities, or under colour of law to subject any inhabitant of a State or Territory to the deprivation of any privileges or immunities (*Perrissal Statutes of United States*, §§ 5597, 5510, 5519).

**PRIVY COUNCIL.** In England the king almost of necessity has been at all times guided by a council. The council, as it existed in the Norman period under the name of *curia regis* (a branch of the larger *commune concilium regni*), exercised judicial, legislative, and administrative functions. It contained the germs of the courts of law and equity, the Houses of Parliament, and the privy council. The Courts of King's Bench and Common Pleas were gradually separated from it and became only courts of first instance, subject to appeal to the king's council. From the time of Edward I. the *concilium ordinarium*, the ordinary or standing council of the king, superseded the *curia regis*. It exercised high judicial functions as the ultimate court of appeal, as the adviser of suitors on petition what court to choose for redress, and as the resort of those who failed to obtain justice in the ordinary course. It was also the supreme administrative body, and as such issued ordinances on matters of a local or temporary nature, with not infrequent usurpations at a later period of jurisdiction belonging more properly to the common law courts or to parliament. The council "consisted of the chief ministers, the chancellor, treasurer, lord steward, lord admiral, lord marshal, the keeper of the privy seal, the chamberlain, treasurer, and comptroller of the household, the chancellor of the exchequer, the master of the wardrobe; and of the judges, king's serjeant, and attorney-general, the master of the rolls, and justices in eyre, who at that time were not the same as the judges at Westminster" (Hallam, *Middle Ages*, vol. iii. p. 205). The growing power of the ordinary council (it does not seem to have been called the privy council until after the reign of Henry VI.) led to many complaints on the part of the Commons, some of which found their expression in statutes. The most worthy of notice is 25 Edw. III. st. 5, c. 4,

characterized by Hallam as probably the most extensively beneficial enactment in the whole body of our laws. Among other provisions it prohibited arbitrary imprisonment and the determination of pleas of freehold before the council. The power of the council expanded or contracted according to the vigour of the king. Its authority was finally reduced by the Long Parliament in 1640 by means of 16 Car. I. c. 10. Assumption of jurisdiction over freeholds was still a grievance, for the Act specially declared that the king's council has no jurisdiction over any man's land, goods, or chattels. From the beginning of Edward III.'s reign the council and the House of Lords were often blended into one assembly, called the *magnum concilium* or great council. As it met only when summoned by writ and not daily, like the ordinary council, it could scarcely have exerted as much authority as the latter. It is therefore not surprising to find it soon split permanently into its two component parts, each retaining both judicial and legislative authority. The privy council still exercises authority of both kinds, though not as completely as the House of Lords. The political importance of the privy council has almost entirely disappeared since the duties of government have been assumed by the cabinet. Its modern legislative jurisdiction is of a subordinate character. Its position as a court of appeal from the foreign possessions of the crown is a strictly logical one. It was always the court for redress where no other redress could be obtained. For the sake of convenience this jurisdiction in cases of what is now called equity was exercised by the chancellor, originally the president of the ordinary council when it sat as a court of justice. But in cases for which equity made no provision, as being out of the bounds of the realm, the privy council still exercises to the full one of the most ancient parts of its jurisdiction. Appeals lay from foreign possessions by virtue of the prerogative, but are now generally regulated by statute. The jurisdiction of the High Court of Delegates over ecclesiastical and admiralty cases was transferred to the privy council in 1832. The council lost its probate appeal jurisdiction in 1857, its admiralty jurisdiction in appeals from England in 1875, from Ireland in 1877.

At the present day members of the privy council become so at the will of the crown, but it is understood that persons in certain positions have an *ex officio* claim to be nominated. The council consists of princes of the royal family or of some of the great officers of state, such as the principal members of the Government, the archbishops and the bishop of London, the judges of the House of Lords, the judicial committee, and the court of appeal, diplomats of high rank, &c. Members of the privy council have the title of "right honourable" and social precedence next after knights of the Garter. Ireland has its own privy council. Scotland has had none of its own since 6 Anne c. 40, which provided for one privy council for Great Britain. The modern jurisdiction of the privy council may be divided into two branches, administrative and judicial.

**Administrative.**—This jurisdiction chiefly depends upon statutory authority, which practically makes of the privy council a subordinate legislature. It is exercised either by the whole council or by committees to which matters are referred by the crown in council. Examples of the latter are the board of trade, the committee of council on education, the local government board (see PUBLIC HEALTH), the universities committee, with temporary powers under the Universities Act, 1877, and the committee of council for the consideration of charters of incorporation under the Municipal Corporations Act, 1852. Cases affecting the constitutional rights of the Channel Islands are referred to a committee for the affairs of Jersey and Guernsey. The committees report to the crown in council, and their report is adopted and enforced by an order in council, published in the *Gazette*. Among other Acts conferring administrative powers upon the privy council are the Pharmacy Act, 1852, as amended by 31 & 32 Vict. c. 121, the Medical Act, 1858, the Foreign Enlistment Act, 1870, the Destructive Insects Act, 1877, the Contagious Diseases (Animals) Act, 1878, the Dentists Act, 1878, the Veterinary Surgeons Act, 1851.

**Judicial.**—Up to 1833 the judicial authority of the privy council was exercised by judicial committees appointed from time to time for the hearing of appeals referred to them by the crown

In council. In 1833 the judicial committee of the privy council was established as a permanent court by 3 & 4 Will. IV. c. 41. Under this and later Acts the judicial committee now consists of the lord president, the lord chancellor, and other persons who fill or have filled high judicial offices (all unpaid), of two retired Indian or colonial judges who receive an allowance for attending the sittings of the committee, and of paid members, now two in number, appointed under 34 & 35 Vict. c. 91. The Appellate Jurisdiction Act, 1876, provides for what is in effect the union of the House of Lords and of the privy council in their judicial capacities by the lords of appeal in ordinary gradually becoming judges of both courts. After the death or resignation of the present paid members these two high judicial bodies will be practically combined, and a near approach will be made to the mediæval *magnam concilium* in an ultimate court of appeal from the whole of the British dominions.

In proceedings under the Church Discipline Act archbishops and bishops who are members of the privy council are members of the judicial committee, 3 & 4 Vict. c. 86. In proceedings under the Public Worship Act, 1874, archbishops and bishops attend as assessors according to rules made by order in council, 39 & 40 Vict. c. 59, § 14. The jurisdiction of the judicial committee is either original or appellate. The original jurisdiction is the less important, and consists of certain powers conferred by the Copyright, Patent, Endowed Schools, and other Acts. The power most frequently exercised is that of extending the term of patents. The appellate jurisdiction is entirely regulated by statute, with the exception of the rarely occurring appeal from orders made by the lord chancellor of Great Britain or of Ireland in exercise of powers conferred by royal sign manual for the custody of idiots and lunatics. Appeals lie from the Archies Court of Canterbury, from a vice-admiralty court abroad, and from the Channel Islands, the Isle of Man, India, and the colonies. Appeals are either of right or by leave. Appeals lie as of right when the value of the matter at issue is of a certain amount (the amount varying according to the appeal rules of the different foreign possessions), and in a few other cases. Appeals lie at the discretion of the judicial committee, on leave being obtained by petition for special leave to appeal. The proceedings in all cases alike, whether original or appellate, are by petition (see PETITION). The petition is addressed to the crown in council in the first instance.

See, in addition to the writers on constitutional history, Sir Harris Nicolas, *Proceedings and Ordinances of the Privy Council of England*; Dicey, *The Privy Council*; Macpherson, *Practice of the Judicial Committee of the Privy Council*. (J. Wt.)

**PRIZE**, or **PRIZE OF WAR**, denotes the ship or goods of an enemy, or *in transitu* to an enemy, captured at sea. Goods captured on land are not prize, but booty of war. To be good prize the capture must be on the high seas or in the territorial waters of one of the belligerents, and must be by an armed vessel duly commissioned by the sovereign of the captor. A capture made in neutral waters is a violation of neutrality, and may be restored at the discretion of the neutral power. Most nations have municipal regulations upon the subject. Thus prize captured in breach of the neutrality of Great Britain may be restored by the High Court of Justice (Admiralty Division) under the powers of the Foreign Enlistment Act, 1870, 33 & 34 Vict. c. 90, § 14. Capture may be actual or constructive. Constructive or joint captors are those who have assisted the actual captors by conveying encouragement to them or intimidation to the enemy. All public ships of war within signalling distance are usually held entitled to share in the proceeds of the capture. This rule is incorporated in the United States code of prize law, the Act of Congress of June 30, 1864. It is not all enemy's property that is good prize. The conflicting interests of neutrals have led to modifications of the general belligerent right of seizing enemy's property wherever found, a right which had become established as part of the general maritime law as early as the *Consolato del Mare* (see vol. vi. p. 317, and SEA LAWS). By the rules laid down in the *Consolato* neutral vessels or neutral goods were to be restored to the owners without compensation for the loss of time and other inconveniences attending capture. This may be said to have been the general law of the sea down to 1856. At the same time it is to be noticed that two doctrines inconsistent with the

original rule had met with the sanction of certain nations, viz., (1) the French doctrine of hostile infection, by which neutral property on an enemy's ship or a neutral ship carrying enemy's property was good prize; (2) the Dutch doctrine, by which the character of the ship alone was regarded—free ship made free goods, enemy ship enemy goods (see Twiss, *Law of Nations*, vol. ii. ch. v.). In 1856 the Declaration of Paris adopted an intermediate system. To this Declaration most nations have acceded (see PRIVATEER). By article 2 of the Declaration, "the neutral flag covers enemy's goods, with the exception of contraband of war." By article 3, "neutral goods, with the exception of contraband of war, are not liable to capture under an enemy's flag." Contraband of war, speaking generally, includes all articles, such as provisions and munitions of war, likely to add to the military or naval resources of the enemy (see CONTRABAND). After the capture has been made, the next proceeding is the determination of its legality. It is now an understood rule of international law that the question of prize or no prize must be determined by a qualified prize court (see below). Captors should send their capture to a convenient port, if possible a port of their own nation or an allied power, for adjudication. They may forfeit their rights by misconduct in this respect. The property in the prize vests in the sovereign, in accordance with the old maxim of law *Parla bello cedunt reipublicæ*. This right attaches both in cases of capture and recapture, subject in the latter case to what is called the *jus postliminii*, that is, the right of the owner of property recaptured from the enemy to have it returned—formerly if the recapture has taken place before the property had been taken within the enemy's territory (*infra præsidia*), at present if less than twenty-four hours has elapsed between the capture and recapture. The right of the recaptors to salvage on recapture is regulated by the municipal law of different nations. By English law one-eighth of the value is the sum usually awarded, but this may be increased to one-fourth under special circumstances. The right does not exist at all if the vessel has been fitted out as a vessel of war by the enemy, 27 & 28 Vict. c. 25, § 40. One-eighth is awarded for recapture from pirates, 13 & 14 Vict. c. 26, § 5. In the United States, by the Prize Act of June 30, 1864, salvage on recapture is allowed according to the circumstances of the case. There is no sum fixed as in England. Although the prize vests in the sovereign, it has been held in England that the captors have an insurable interest in the prize immediately after capture and before condemnation on the ground that under the Prize Act the captors have a certain expectation of profit upon the safe arrival of the prize in port, and that they are liable to condemnation in damages and costs if the capture be unjustifiable. By the general maritime law a prize may be released upon ransom; but it has been the general policy of European nations to discountenance ransom as less beneficial to the state than the detention of a prize. Thus an Act of 1782, and subsequent Acts, avoided ransom bills given by British subjects, and subjected a commander giving one to an enemy to penalties, unless in either case the circumstances were such as to justify the giving or taking of the bill. The Naval Prize Act, 1864, is less strict in its terms. It enacts that the queen in council may from time to time in relation to any war make such orders as are expedient as to contracts for the ransoming of a ship or goods; contravention of the orders makes the contract void and renders the offender liable to a penalty not exceeding £500, 27 & 28 Vict. c. 25, § 45. By the Naval Discipline Act, 1866, a commanding officer making an unlawful agreement for ransom is liable to be dismissed from the service, 29 & 30 Vict. c. 109, § 41. The

United States have never prohibited ransom bills. The rights of the sovereign to prize may be waived, as was formerly done by the crown of Great Britain in the case of privateers (see *PRIVATEER*).

Many statutes dealing with prize have been enacted at different times in England. The first general Prize Act was 6 Anne c. 12. The Act that now regulates prize is the Naval Prize Act, 1864, already referred to. Various offences in relation to prize are dealt with by the Naval Prize Act and the Naval Discipline Act. Such are false swearing in a prize cause or appeal, taking money, &c., out of a ship before condemnation, ill-using persons on board the prize, &c., or breaking bulk with a view to embezzlement. Prize is subject to the usual customs regulations. The United States Prize Act is the Act of June 20, 1864, just seven days later in date than the British Prize Act. The two Acts are similar in character, but the United States Act is more full and definite than the British, as it deals with some matters which in Great Britain are left to the discretion of the executive.

**Prize Court.**—This is a court sitting by the commission of the the sovereign of the captor for the determination of prize causes. A capture does not become good prize until condemnation by a prize court. As a general rule the court must be commissioned by the sovereign, must sit in the country of the captor, and must be in possession of the prize. In the case of allied powers, it is usually agreed (as it was between Great Britain and France in 1854) that the decision shall be made by a court of the country to which the officer in command belongs. A prize court may sit in the territory of an ally, though this is irregular; but it is a violation of neutrality to constitute a prize court within the limits of a neutral power. A prize may, however, in case of necessity be brought into a neutral port and sold there under the decree of a prize court, subject to objection on the part of the neutral Government. The sentence of a prize court is, where the jurisdiction is well-founded, a judgment *in rem* and entitled to universal respect. In the British dominions the prize courts are such courts as the crown or parliament invests with authority in prize matters. In practice these are the High Court of Justice (Admiralty Division) and the Vice-Admiralty Courts abroad. By the Naval Prize Act, 1864, the High Court of Admiralty of England (now represented by the Admiralty Division) has jurisdiction as a prize court throughout the British dominions. It is to be noticed that this jurisdiction is entirely derivative; the court has no original prize jurisdiction as it has original instance jurisdiction. The prize jurisdiction of Scotch courts was vested in the High Court of Admiralty of England by 6 Geo. IV. c. 129, § 57. In the United States (in accordance with Art. III. § 2 of the constitution, "The judicial power shall extend to . . . all cases of admiralty and maritime jurisdiction") the prize courts are the district courts, the State courts having no jurisdiction. The procedure of a prize court is simple in its character. In Great Britain and the United States standing interrogatories are administered to the captors. The case is heard upon the depositions of the witnesses in answer to the interrogatories, and upon the ship's papers, which it is the duty of the captor to forward to a port of his country for deposit in the court. The flag is regarded as *prima facie* evidence of the nationality of a captured vessel. The pleadings are not technical. A libel is filed, followed by a monition to parties interested. If the cause be not prosecuted, the court will issue a monition to the captors to proceed. A prize court has power to order matters incidental to the cause, such as delivery and appraisement and sale. It also distributes prize money in some cases (see below). The procedure of prize courts in the British dominions may be regulated by order in council under the powers of the Naval Prize Act, 1864; in the United States it depends upon the Prize Act of June 20, 1864. An appeal lies in England from the Admiralty Division to the Court of Appeal and thence to the House of Lords, from the Vice-Admiralty Courts abroad to the Judicial Committee of the Privy Council. In the United States it lies to the supreme court where the matter in dispute exceeds 2000 dollars, or involves a question of general importance. In addition to prize proper, prize courts have had jurisdiction in some analogous matters conferred on them by statute. Thus a prize court in the British dominions has jurisdiction over (1) enemy's property captured in a conjoint expedition of land and naval forces, 2 & 3 Will. IV. c. 53, § 30, or captured on land by a naval or naval and military force acting either alone or with allied forces, 27 & 25 Vict. c. 25, §§ 34, 35; (2) petitions of right where the subject-matter of a petition arises out of the exercise of any belligerent right by the crown, or would be cognizable in a prize court if the same were a matter in dispute between private persons, § 52. Questions of booty of war may be referred to the Admiralty Division as a prize court, 2 & 4 Vict. c. 65, § 22. The United States prize courts have by the Act of 1854 jurisdiction over property captured in an insurrection.<sup>1</sup>

**Prize Money.**—The term prize money is used in a wider sense than the term prize. It extends to any reward granted by the state for the capture of enemy's property whether by land or sea. (1) The Act consolidating the right to and distribution of army prize money is the Army Prize Act, 1832, 2 & 3 Will. IV. c. 53. The right and interest of troops to prize money and bounty money is at the discretion of the crown, and is to be distributed in such proportions as the crown may direct. It is to be noticed that capture by troops of an enemy's ship in a road, river, haven, or creek of the enemy gives a right to prize money in this sense, though it is not prize proper, not having been captured at sea by an armed ship. Deserters are not entitled to prize money. Shares not claimed within six years are forfeited. A list of persons entitled is transmitted to Chelsea Hospital, the treasurer of which distributes the money either to such persons or their assignees, or to the regimental agent, according to the rules laid down in the Act. Prize money may be assigned subject to certain conditions. In the case of officers the assignment must express the consideration money actually paid for the assignment; in the case of non-commissioned officers or seamen the assignment is only valid where there is no regimental agent. In conjoint expeditions of land and naval forces, the share of the land forces is to be paid to the treasurer of Chelsea Hospital. By 27 & 25 Vict. c. 26, § 3, prize money not exceeding £50 may be paid without probate or letters of administration. By 39 Vict. c. 14, the accounts are to be laid before parliament. In the United States provision was made by several Acts of Congress that officers and soldiers who had served in certain wars should be entitled to warrants for bounty-lands as a reward for their services. (2) For the right to prize money where the captor at sea is not a public ship of war, see *PRIVATEER*. Where the captor is a public ship of war of Great Britain, the officers and crew have only such interest in the proceeds of prize as the crown may from time to time grant them. This interest is subject to forfeiture for misconduct in relation to the prize, 27 & 25 Vict. c. 25, §§ 36, 55. In the United States, by the Prize Act of 1864, the whole proceeds go to the captor where the prize is of superior or equal force, one-half to the captor and one-half to the United States where the prize is of inferior force. The prize money accruing to the United States forms part of the fund for pensions. Besides a share of the prize, prize bounty is generally given. By the Naval Prize Act, 1864, this is at the rate of £5 for each person on board the enemy's ship, if a ship of war, 27 & 25 Vict. c. 25, § 42. By the United States Act of 1864, the rate is 200 dollars if the prize is of superior or equal force, 100 if of inferior force. The distribution of prize money and prize bounty in Great Britain is regulated by the Naval Agency and Distribution Act, 1864, 27 & 25 Vict. c. 24. The money is distributed under the direction of the lords of the Admiralty in the proportions specified in a royal proclamation or order in council. The proportions are graduated according to rank (see vol. xvii. p. 296). Assignment of a share by a petty officer or seaman or a non-commissioned officer of marines or marines is void unless in accordance with orders in council. All forfeited and unclaimed shares, and a percentage of 5 per cent. out of the proceeds and grants, are carried to the account of the naval prize cash balance. The Admiralty Division has the sole right of determining disputes as to distribution or investment. In the United States the distribution is regulated by the Act of 1864. The distribution is by the district court; it is a judicial act, not, as in Great Britain, the act of a Government department. The proportions too are fixed by statute—not left, as in Great Britain, to the discretion of the executive. The commanding officer of a fleet or squadron has one-twentieth allotted to him, of a division one-fiftieth, a fleet captain one-hundredth, the commander of a single vessel one-tenth of the amount awarded to the vessel; the residue share in proportion to their pay. Prize money is paid into the treasury of the United States to be distributed according to the decree of the court. Ransom money, salvage, bounty, and proceeds of condemned property are distributable as prize money. Assignments of prize money must be attested by the commanding officer and the paymaster. There are certain cases where money is granted to the officers and crew of vessels making captures which are not prize in the strict sense of the word. Under this head may be classed the salvage on recapture already mentioned, besides the cases provided for in the following enactments. By 22 & 23 Car. II. c. 11, § 10, 2 per cent. of the value of the ship defended may be awarded to those wounded and the representatives of those slain in the defence of a merchant ship against pirates. By the Customs Act, 1876, 39 & 40 Vict. c. 36, §§ 210-216, rewards may be granted to officers of the customs out of the penalties for goods seized. By the Slave Trade Act, 1873, 36 & 37 Vict. c. 88, §§ 11, 12, a bounty of £5 per slave or of £4 per ton is payable to the officers and crew of one of Her Majesty's ships upon capture of a slave ship. Where the capture is not by a ship of war, the bounty is one-third of the value of the ship seized, and a bounty of £5 for each slave. By an Act of Congress of March 3, 1819, a bounty of 25 dollars is given for each slave captured, and the proceeds of condemned slave ships are divided between the United States and the captors, half to each. (J. W. F.)

<sup>1</sup> For the procedure of prize courts see *Smry, On Prize Courts*; Phillimore, *International Law*, vol. III. § 1. 21; Lushington, *Manual of Naval Prize Law*.

## PROBABILITY

THE mathematical theory of probability is a science which aims at reducing to calculation, where possible, the amount of credence due to propositions or statements, or to the occurrence of events, future or past, more especially as contingent or dependent upon other propositions or events the probability of which is known.

Any statement or (supposed) fact commands a certain amount of credence, varying from zero, which means conviction of its falsity, to absolute certainty, denoted by unity. An even chance, or the probability of an event which is as likely as not to happen, is represented by the fraction  $\frac{1}{2}$ . It is to be observed that  $\frac{1}{2}$  will be the probability of an event about which we have no knowledge whatever, because if we can see that it is more likely to happen than not, or less likely than not, we must be in possession of some information respecting it. It has been proposed to form a sort of thermometrical scale, to which to refer the strength of the conviction we have in any given case. Thus if the twenty-six letters of the alphabet have been shaken together in a bag, and one letter be drawn, we feel a very feeble expectation that A has been the one taken. If two letters be drawn, we have still very little confidence that A is one of them; if three be drawn, it is somewhat stronger; and so on, till at last, if twenty-six be drawn, we are certain of the event, that is, of A having been taken.

Probability, which necessarily implies uncertainty, is a consequence of our ignorance. To an omniscient Being there can be none. Why, for instance, if we throw up a shilling, are we uncertain whether it will turn up head or tail? Because the shilling passes; in the interval, through a series of states which our knowledge is unable to predict or to follow. If we knew the exact position and state of motion of the coin as it leaves our hand, the exact value of the final impulse it receives, the laws of its motion as affected by the resistance of the air and gravity, and finally the nature of the ground at the exact spot where it falls, and the laws regulating the collision between the two substances, we could predict as certainly the result of the toss as we can which letter of the alphabet will be drawn after twenty-five have been taken and examined.

The probability, or amount of conviction accorded to any fact or statement, is thus essentially subjective, and varies with the degree of knowledge of the mind to which the fact is presented (it is often indeed also influenced by passion and prejudice, which act powerfully in warping the judgment),—so that, as Laplace observes, it is affected partly by our ignorance partly by our knowledge. Thus, if the question were put, Is lead heavier than silver? some persons would think it is, but would not be surprised if they were wrong; others would say it is lighter; while to a worker in metals probability would be superseded by certainty. Again, to take Laplace's illustration, there are three urns A, B, C, one of which contains black balls, the other two white balls; a ball is drawn from the urn C, and we want to know the probability that it shall be black. If we do not know which of the urns contains the black balls, there is only one favourable chance out of three, and the probability is said to be  $\frac{1}{3}$ . But if a person knows that the urn A contains white balls, to him the uncertainty is confined to the urns B and C, and therefore the probability of the same event is  $\frac{1}{2}$ . Finally to one who had found that A and B both contained white balls, the probability is converted into certainty.

In common language, an event is usually said to be likely or probable if it is more likely to happen than not,

or when, in mathematical language, its probability exceeds  $\frac{1}{2}$ ; and it is said to be improbable or unlikely when its probability is less than  $\frac{1}{2}$ . Not that this sense is always adhered to; for, in such a phrase as "It is likely to thunder to-day," we do not mean that it is more likely than not, but that in our opinion the chance of thunder is greater than usual; again, "Such a horse is likely to win the Derby," simply means that he has the best chance, though according to the betting that chance may be only  $\frac{1}{4}$ . Such unsteady and elliptical employment of words has of course to be abandoned and replaced by strict definition, at least mentally, when they are made the subjects of mathematical analysis. *Certainty*, or absolute conviction, also, as generally understood, is different from the mathematical sense of the word certainty. It is very difficult and often impossible, as is pointed out in the celebrated *Grammar of Assent*, to draw out the grounds on which the human mind in each case yields that conviction, or assent, which, according to Newman, admits of no degrees, and either is entire or is not at all.<sup>1</sup> If, when walking on the beach, we find the letters "Constantinople" traced on the sand, we should feel, not a strong impression, but absolute certainty, that they were characters not drawn at random, but by one acquainted with the word so spelt. Again, we are certain of our own death as a future event; we are certain, too, that Great Britain is an island; yet in all such cases it would be very difficult, even for a practised intellect, to present in logical form the evidence, which nevertheless has compelled the mind in each instance to concede the point.<sup>2</sup> Mathematical certainty, which means that the contrary proposition is inconceivable, is thus different, though not perhaps as regards the force of the mental conviction, from moral or practical certainty. It is questionable whether the former kind of certainty is not entirely hypothetical, and whether it is ever attainable in any of the affairs or events of the real world around us. The truth of no conclusion can rise above that of the premises, of no theorem above that of the data. That two and two make four is an incontrovertible truth; but before applying even it to a concrete instance we have to be assured that there were really two in each constituent group; and we can hardly have mathematical certainty of this, as the strange freaks of memory, the tricks of conjurors, &c., have often made apparent.

There is no more remarkable feature in the mathematical theory of probability than the manner in which it has been found to harmonize with, and justify, the conclusions to which mankind have been led, not by reasoning, but by instinct and experience, both of the individual and of the race. At the same time it has corrected, extended, and invested them with a definiteness and precision of which these crude, though sound, appreciations of common sense were till then devoid. Even in cases where the theoretical result appears to differ from the common-sense view, it often happens that the latter may, though perhaps unknown to the mind itself, have taken account of circumstances in the case omitted in the data of the

<sup>1</sup> "There is a sort of leap which most men make from a high probability to absolute assurance . . . analogous to the sudden consilience, or springing into one, of the two images seen by binocular vision, when gradually brought within a certain proximity."—Sir J. Herschel, in *Edin. Review*, July 1850.

<sup>2</sup> Archbishop Whately's *jeu d'esprit*, *Historic Doubts respecting Napoleon Bonaparte*, is a good illustration of the difficulties there may be in proving a conclusion the certainty of which is absolute.

theoretical problem. Thus, it may be that a person accords a lower degree of credence to a fact attested by two or more independent witnesses than theory warrants,—the reason being that he has unconsciously recognized the possibility of collusion, which had not been presented among the data. Again, it appears from the rules for the credibility of testimony that the probability of a fact may be diminished by being attested by a new witness, viz., in the case where his credibility is less than  $\frac{1}{2}$ . This is certainly at variance with our natural impression, which is that our previous conviction of any fact is clearly not weakened, however little it be intensified, by any fresh evidence, however suspicious, as to its truth. But on reflexion we see that it is a practical absurdity to suppose the credibility of any witness less than  $\frac{1}{2}$ —that is, that he speaks falsehood oftener than truth—for all men tell the truth probably nine times out of ten, and only deviate from it when their passions or interests are concerned. Even where his interests are at stake, no man has any preference for a lie, as such, above the truth; so that his testimony to a fact will at worst leave the antecedent probability exactly what it was.

A celebrated instance of the confirmation and completion by theory of the ordinary view is afforded by what is known as James Bernoulli's theorem. If we know the odds in favour of an event to be three to two, as for instance that of drawing a white ball from a bag containing three white and two black, we should certainly judge that if we make five trials we are more likely to draw white three times and black twice than any other combination. Still, however, we should feel that this was very uncertain; instead of three white, we might draw white 0, 1, 2, 4, or 5 times. But if we make say one thousand trials, we should feel confident that, although the numbers of white and black might not be in the proportion of three to two, they would be very nearly in that proportion. And the more the trials are multiplied the more closely would this proportion be found to obtain. This is the principle upon which we are continually judging of the possibility of events from what is observed in a certain number of cases.<sup>1</sup> Thus if, out of ten particular infants, six are found to live to the age of twenty, we judge, but with a very low amount of conviction, that nearly six-tenths of the whole number born live to twenty. But if, out of 1,000,000 cases, we find that 600,000 live to be twenty, we should feel certain that the same proportion would be found to hold almost exactly were it possible to test the whole number of cases, say in England during the 19th century. In fact we may say, considering how seldom we know *a priori* the probability of any event, that the knowledge we have of such probability in any case is entirely derived from this principle, viz., that the proportion which holds in a large number of trials will be found to hold in the total number, even when this may be infinite,—the deviation or error being less and less as the trials are multiplied.

Such no doubt is the verdict of the common sense of mankind, and it is not easy to say upon what considerations it is based, if it be not the effect of the unconscious habit which all men acquire of weighing chances and probabilities, in the state of ignorance and uncertainty which human life is. It is now extremely interesting to see the results of the unerring methods of mathematical analysis when applied to the same problem. It is a very

difficult one, and James Bernoulli tells us he reflected upon it for twenty years. His methods, extended by De Moivre and Laplace, fully confirm the conclusions of rough common sense; but they have done much more. They enable us to estimate exactly how far we can rely on the proportion of cases in a large number of trials, truly representing the proportion out of the total number—that is, the real probability of the event. Thus he proves that if, as in the case above mentioned, the real probability of an event is  $\frac{3}{5}$ , the odds are 1000 to 1 that, in 25,550 trials, the event shall occur not more than 15,841 times and not less than 14,819 times,—that is, that the deviation from 15,330, or  $\frac{3}{5}$  of the whole, shall not exceed  $\frac{1}{50}$  of the whole number of trials.

The history of the theory of probability, from the celebrated question as to the equitable division of the stakes between two players on their game being interrupted, proposed to Pascal by the Chevalier de Méré in 1654, embracing, as it does, contributions from almost all the great names of Europe during the period, down to Laplace and Poisson, is elaborately and admirably given by Mr Todhunter in his *History* of the subject, now a classical work. It was not indeed to be anticipated that a new science which took its rise in games of chance, and which had long to encounter an obloquy, hardly yet extinct, due to the prevailing idea that its only end was to facilitate and encourage the calculations of gamblers, could ever have attained its present status—that its aid should be called for in every department of natural science, both to assist in discovery, which it has repeatedly done (even in pure mathematics), to minimize the unavoidable errors of observation, and to detect the presence of causes as revealed by observed events. Nor are commercial and other practical interests of life less indebted to it: wherever the future has to be forecasted, risk to be provided against, or the true lessons to be deduced from statistics, it corrects for us the rough conjectures of common sense, and decides which course is really, according to the lights of which we are in possession, the wisest for us to pursue. It is *sui generis* and unique as an application of mathematics, the only one, apparently, lying quite outside the field of physical science. De Moivre has remarked that, “some of the problems about chance having a great appearance of simplicity, the mind is easily drawn into a belief that their solution may be attained by the mere strength of natural good sense”; and it is with surprise we find that they involve in many cases the most subtle and difficult mathematical questions. It has been found to tax to the utmost the resources of analysis and the powers of invention of those who have had to deal with the new cases and combinations which it has presented. Great, however, as are the strictly mathematical difficulties, they cannot be said to be the principal. Especially in the practical applications, to detach the problem from its surroundings in *rerum natura*, discarding what is non-essential, rightly to estimate the extent of our knowledge respecting it, neither tacitly assuming as known what is not known, nor tacitly overlooking some datum, perhaps from its very obviousness, to make sure that events we are taking as independent are not really connected, or probably so,—such are the preliminaries necessary before the question is put in the scientific form to which calculation can be applied, and failing which the

<sup>1</sup> So it is said, “the tree is known by its fruits”; “practice is better than theory”; and the universal sense of mankind judges that the safest test of any new invention, system, or institution is to see how it works. So little are we able by *a priori* speculations to forecast the thousand obstacles and disturbing influences which manifest themselves when any new cause or agent is introduced as a factor in the world's affairs.

<sup>2</sup> Men were surprised to hear that not only births, deaths, and marriages, but the decisions of tribunals, the results of popular elections, the influence of punishments in checking crime, the comparative value of medical remedies, the probable limits of error in numerical results, in every department of physical inquiry, the detection of causes, physical, social, and moral, nay, even the weight of evidence and the validity of logical argument, might come to be surveyed with the lynx-eyed scrutiny of a dispassionate analysis.—Sir J. Herschel.

result of the mathematician will be but an *ignoratio elenchi*—a correct answer, but to a different question.

From its earliest beginnings, a notable feature in our subject has been the strange and insidious manner in which errors creep in—often misleading the most acute minds, as in the case of D'Alembert—and the difficulty of detecting them, even when one is assured of their presence by the evident incorrectness of the result. This is probably in many cases occasioned by the poverty of language obliging us to use one term in the same context for different things—thus introducing the fallacy of ambiguous middle; *e.g.*, the same word “probability” referring to the same event may sometimes mean its probability *before* a certain occurrence, sometimes *after*; thus the chance of a horse winning the Derby is different after the Two Thousand from what it was before. Again, it may mean the probability of the event according to one source of information, as distinguished from its probability taking everything into account; for instance, an astronomer thinks he can notice in a newly-discovered planet a rotation from east to west; the probability that this is the case is of course that of his observations in like cases turning out correct, if we had no other source of information; but the actual probability is less, because we know that at least the vast majority of the planets and satellites revolve from west to east. It is easy to see that such employment of terms in the same context must prove a fruitful source of fallacies; and yet, without wearisome repetitions, it cannot always be avoided. But, apart from mere logical errors, the main stumbling-block is no doubt the uncertainty as to the limits of our knowledge in each case, or—though this may seem a contradiction in terms—the difficulty of knowing what we do know; and we certainly err as often in forgetting or ignoring what we do know, as in assuming what we do not. It is a not uncommon popular delusion to suppose that if a coin has turned up head, say five times running, or the red has won five times at roulette, the same event is likely to occur a sixth time; and it arises from overlooking (perhaps from the imagination being struck by the singularity of the occurrence) the *a priori* knowledge we possess, that the chance at any trial is an even one (supposing all perfectly fair); the mind thus unconsciously regards the event simply as one that has recurred five times, and therefore judges, correctly, that it is very likely to occur once more. Thus if we are given a bag containing a number of balls, and we proceed to draw them one by one, and the first five drawn are white, the odds are 6 to 1 that the next will be white,—the slight information afforded by the five trials being thus of great importance, and strongly influencing the probabilities of the future, when it is all we have to guide us, but absolutely valueless, and without influence on the future, when we have *a priori* certain information. The lightest air will move a ship which is adrift, but has simply no effect on one securely moored.

It is not to be supposed that the results arrived at when the calculus of probabilities is applied to most practical questions are anything more than approximations; but the same may be said of almost all such applications of abstract science. Partly from ignorance of the real state of the case, partly from the extreme intricacy of the calculations requisite if all the conditions which we do or might know are introduced, we are obliged to substitute in fact, for the actual problem, a simpler one approximately representing it. Thus, in mechanical questions, assumptions such as that the centre of gravity of an actual sphere is at its centre, that the friction of the rails on a railway is constant at different spots or at different times, or that in the rolling of a heavy body no depression is produced by its weight in the supporting substance,

are instances of the convenient fictions which simplify the real question, while they prevent us accepting the result as more than something near the truth. So in probability, the chance of life of an individual is taken from the general tables (unless reasons to the contrary are very palpable) although, if his past history, his mode of life, the longevity of his family, &c., were duly weighed, the general value ought to be modified in his case; again, in attempting to estimate the value of the verdict of a jury, whether unanimous or by a majority, each man is supposed to give his honest opinion,—feeling and prejudice, or pressure from his fellow-jurors, being left out of the account. Again, the value of an *expectation* to an individual is taken to be measured by the sum divided by his present fortune, though it is clearly affected by other circumstances, as the number of his family, the nature of his business, &c. An event has been found to occur on an average once a year during a long period: it is not difficult to show that the chance of its happening in a particular year is  $1 - e^{-1}$ , or 2 to 1 nearly. But, on examining the record, we observe it has never failed to occur during three years running. This fact increases the above chance; but to introduce it into the calculation at once renders the question a very difficult one. Even in games of chance we are obliged to judge of the relative skill of two players by the result of a few games; now one may not have been in his usual health, &c., or may have designedly not played his best; when he did win he may have done so by superior play, or rather by good luck; again, even in so simple a case as pitch and toss, the coin may, in the concrete, not be quite symmetrical, and the odds of head or tail not quite even.

Not much has been added to our subject since the close of Laplace's career. The history of science records more than one parallel to this abatement of activity. When such a genius has departed, the field of his labours seems exhausted for the time, and little left to be gleaned by his successors. It is to be regretted that so little remains to us of the inner working of such gifted minds, and of the clue by which each of their discoveries was reached. The didactic and synthetic form in which these are presented to the world retains but faint traces of the skilful inductions, the keen and delicate perception of fitness and analogy, and the power of imagination—though such a term may possibly excite a smile when applied to such *dry* subjects—which have doubtless guided such a master as Laplace or Newton in shaping out each great design—only the minor details of which have remained over, to be supplied by the less cunning hand of commentator and disciple.

We proceed to enumerate the principal divisions of the theory of probability and its applications. Under each we will endeavour to give at least one or two of the more remarkable and suggestive questions which belong to it,—especially such as admit of simplification or improvement in the received solutions; in such an article as the present we are debarred from attempting even an outline of the whole. We will suppose the general fundamental principles to be already known to the reader, as they are to be now found in several elementary works, such as Todhunter's *Algebra*, Whitworth's *Choice and Chance*, &c.

Many of the most important results are given under the apparently trifling form of the chances in drawing balls from an urn, &c., or seem to relate to games of chance, as dice or cards, but are in reality of far wider application,—this form being adopted as the most definite and lucid manner of presenting the chances of events occurring under circumstances which may be assimilated, more or less closely, to such cases.

I. DETERMINATION OF THE PROBABILITIES OF COMPOUND EVENTS, WHEN THE PROBABILITIES OF THE SIMPLE EVENTS ON WHICH THEY DEPEND ARE KNOWN.

1. Under this head come a very large and diversified range of questions; a very few of the most important are all that we can give. One great class relates to the fulfilment of given conditions in repeated trials as to the same event, knowing the probability of what will happen in each trial.

2. Let there be an event which must turn out in one of two ways, W and B (as in drawing a ball from an urn containing white and black balls only); let the respective probabilities for each trial be  $p, q$ ; so that  $p+q=1$ . Let two trials be made: the four possible cases which may arise are

WW, WB, BW, BB.

The probability of the first is  $p^2$ , of the second  $pq$ , of the third  $pq$ , of the fourth  $q^2$ . Thus the probability of a white and a black ball being drawn in an assigned order is  $pq$ ; but that of a white and a black in any order is  $2pq$ .

Suppose now  $n$  trials to be made. The probability of W every time is  $p^n$ ; that of B once and W  $(n-1)$  times in an assigned order is  $p^{n-1}q$ , but if the order is indifferent it is  $np^{n-1}q$ ; that of B occurring twice only is  $p^{n-2}q^2$  if the order is given, but  $\frac{n(n-1)}{2}p^{n-2}q^2$  in any order; and so on. We have then this result:—in the binomial expansion

$$(p+q)^n = 1 = p^n + np^{n-1}q + \frac{n(n-1)}{2}p^{n-2}q^2 + \frac{n(n-1)(n-2)}{3}p^{n-3}q^3 + \dots \quad (1),$$

the terms in their order give the probabilities of the event W happening  $n$  times; of W  $(n-1)$  times and B once; of W  $(n-2)$  times and B twice; and so on,—the sum of the whole giving 1, that is, certainty.

3. As an example, let A and B be two players whose respective chances of winning one game are  $p$  and  $q$ ; to find the probability of A winning  $m$  games before B wins  $n$  games, the play terminating when either of these events has occurred.

The chance of A winning the first  $m$  games is  $p^m$ . The chance of his winning in the first  $m+1$  games is  $mp^{m-1}q$ ,  $p=mp^m q$ ; for he must have won  $m-1$  games out of the first  $m$ , and then win the  $(m+1)$ th; otherwise we should be including the first case. Again, the chance of A winning in the first  $m+2$  games is, in like manner,  $\frac{(m+1)m}{2}p^{m-2}q^2$ ; and so on. Now the match must be decided at latest by the  $(m+n-1)$ th game; for, if A fails to win  $m$  games by that time, B must have won  $n$ . Hence the chance of A winning the match is

$$p^m \left\{ 1 + mq + \frac{m(m+1)}{2}q^2 + \dots + \frac{m(m+1) \dots (m+n-2)}{(n-1)!} q^{n-1} \right\}.$$

Thus, if A's skill be double that of B, the chance that A wins four games before B wins two is  $\frac{112}{243}$ . That of B winning is  $\frac{131}{243}$ .

If A and B agree to leave off playing before the match is decided, the stakes ought clearly to be divided between them in proportion to their respective probabilities of winning, as given above,—putting for  $m$  and  $n$  the numbers of games required to be won, at any given point of the match, by A and B respectively.

This was one of the questions proposed to Pascal by the Chevalier de Méré in the year 1654.

4. In the expansion (1) it may be asked which combination of the events W, B is most likely to occur in the  $n$  trials. As the ratio of the 2d term to the 1st is  $\frac{nq}{p}$ , of the 3d to the 2d  $\frac{n-1}{2} \frac{q}{p}$ ,

and of the  $(r+1)$ th to the  $r$ th  $\frac{n-r+1}{r} \frac{q}{p}$ , so long as this ratio continues to increase the terms will increase. The condition, therefore, for the  $r$ th term to be the greatest is

$$\frac{n-r+1}{r} < \frac{p}{q}, \text{ or } > (n+1)q;$$

that is,  $r$  is the next integer above  $(n+1)q$ .

We conclude that if  $r$  is the next integer below  $(n+1)q$  the  $(r+1)$ th term is the greatest—that is, it is most likely that the event W occurs  $n-r$  times and B  $r$  times. If  $(n+1)q$  should be an integer  $(r)$ , B is as likely to occur  $r$  as  $r+1$  times; and either is more probable than any other number. Thus, in twelve throws of a die, the ace is more likely to turn up twice than any other number; while in eleven throws it is as likely to turn up once only as twice.

It is important to remark that, if the number of trials  $n$  be very large, we may treat  $qn$  and  $pn$  as whole numbers, and conclude that the event W is more likely to happen  $pn$  times and B  $qn$  times than in any other proportion.

5. Among the many questions which relate to the occurrence of

different combinations in successive trials as to the same event, one is as to the chances for a succession, or run, of the same result several times.

Let us consider the very simple case—In  $n$  throws of a coin, what is the chance that head occurs (at least) twice running?

This will be an instance of the aid afforded by the calculus of finite differences in questions on probability. Let  $u_r$  = the number of cases of  $r$  throws of a coin in which head turns up twice running, the whole number of cases being of course  $2^r$ . Now if we consider the value of  $u_{n+3}$ , it includes  $2u_{n+2}$ , because the  $(n+3)$ th throw may turn up two ways; but it includes also those cases when head turns up in the last two throws, tail in the preceding one, and no run of two heads occurs in the  $n$  preceding ones. The number of these cases is  $2^n - u_n$ . We have therefore the equation

$$u_{n+3} = 2u_{n+2} + 2^n - u_n \quad (2).$$

If E be an operator such that  $Eu_r = u_{r+1}$ , equation (2) is

$$(E^3 - 2E^2 + 1)u_n = 2^n;$$

or,

$$(E-1)(E^2-E-1)u_n = 2^n;$$

so that, if we put  $\alpha, \beta$  for the roots of the equation  $E^2-E-1=0$ ,

$$u_n = 2^n + A + B\alpha^n + C\beta^n \quad (3),$$

since  $u_n = 2^n$  is a particular solution of (2),—A, B, C being three undetermined constants.

Now in two throws there is one case where head turns up twice, and in three throws there are three cases; hence we have

$$\begin{aligned} u_1 &= 0 = 2 + A + B\alpha + C\beta \\ u_2 &= 1 = 4 + A + B\alpha^2 + C\beta^2 \\ u_3 &= 3 = 8 + A + B\alpha^3 + C\beta^3; \end{aligned}$$

and, remembering that  $\alpha^2 = \alpha + 1$ ,  $\beta^2 = \beta + 1$ , we shall easily find from these

$$A=0, B=\frac{\alpha^2}{\beta-\alpha}, C=\frac{\beta^2}{\alpha-\beta};$$

so that

$$u_n = 2^n - \frac{\alpha^{n+2} - \beta^{n+2}}{\alpha - \beta} \quad (4).$$

Now

$$\alpha = \frac{1+\sqrt{5}}{2}, \beta = \frac{1-\sqrt{5}}{2};$$

expanding by the binomial theorem and reducing,

$$u_n = 2^n - \frac{n+2}{2^{n+1}} \left\{ 1 + \frac{(n+1)n}{3} + \frac{(n+1)n(n-1)(n-2)}{15} + \dots \right\} \quad (5);$$

dividing by the total number of cases  $2^n$ , we have for the probability of head turning up at least twice running in  $n$  throws

$$p_n = 1 - \frac{n+2}{2^{n+1}} \left\{ 1 + \frac{(n+1)n}{3} + \frac{(n+1)n(n-1)(n-2)}{15} + \dots \right\} \quad (6).$$

Another method of obtaining the same result is to consider the number of cases in which head never occurs twice running; let  $u_n$  be this number, then  $2^n - u_n$  must be the number of cases when head occurs at least twice successively. Consider the value of  $u_{n+2}$ ; if the last or  $(n+2)$ th throw be tail,  $u_{n+2}$  includes all the cases ( $u_{n+1}$ ) of the  $n+1$  preceding throws which gave no succession of heads; and if the last be head the last but one must be tail, and these two may be preceded by any one of the  $u_n$  favourable cases for the first  $n$  throws. Consequently

$$u_{n+2} = u_{n+1} + u_n.$$

If  $\alpha, \beta$ , as before, are the roots of the quadratic  $E^2-E-1=0$ , this equation gives

$$u_n = A\alpha^n + B\beta^n$$

Here A and B are easily found from the conditions  $u_1=2, u_2=3$ ; viz.,

$$A = \frac{\alpha^2}{\alpha-\beta}, B = \frac{\beta^2}{\beta-\alpha},$$

whence

$$u_n = \frac{n+2}{2^{n+1}} \left\{ 1 + \frac{(n+1)n}{1 \cdot 2 \cdot 3} + \dots \right\}$$

as in eq. (5). The probability that head never turns up twice running is found by dividing this by  $2^n$ , the whole number of cases. This probability of course becomes smaller and smaller as the number of trials ( $n$ ) is increased.

6. Let us consider the chance of a run of three heads or tails during  $n$  throws,—that of a run of two heads or tails being evidently  $\frac{2^n-2}{2^n} = 1 - \frac{1}{2^{n-1}}$ , as there are but two cases out of the  $2^n$  which are alternately head and tail.

Let  $u_r$  be the number of cases, during  $r$  throws, which give at least one succession of three heads or three tails. Consider the value of  $u_{n+3}$ ; it includes  $2u_{n+2}$ , as the last throw may be head or tail; but, besides these, every case of the first  $n$  throws which contains no run of three gives rise to one new case of the  $n+3$  having a run of three; thus, if the  $n$ th throw be head, the last four may be HTTT, or THHH if the  $n$ th be tail. Hence

$$u_{n+3} = 2u_{n+2} + 2^n - u_n,$$

the same equation of differences as (2). Its solution is equation (3), in which, if we determine the constants by the conditions  $u_1=0$ ,  $u_2=0$ ,  $u_3=2$ , and divide by  $2^n$ , we find for the probability of a run of three of either event during  $n$  trials

$$= \frac{u_n}{2^n} = 1 - \frac{n+1}{2^{2n-1}} \left\{ 1 + \frac{n(n-1)}{3} 5 + \frac{n(n-1)(n-2)(n-3)}{5} 5^2 + \dots \right\} 7.$$

Comparing this result with (6) we find that the chance of a run of two heads in  $n$  trials is equal to the chance of a run of three, of either heads or tails, in  $n+1$  trials.

7. If an event may turn out on each trial in  $a+b$  ways, of which  $a$  are favourable and  $b$  unfavourable (thus a card may be drawn from a pack in fifty-two ways, twelve of which give court cards), and if we consider the probability that during  $n$  trials there shall occur a run of at least  $p$  favourable results, it is not difficult to see that ( $u_r$  denoting the number of ways this may occur in  $r$  trials)

$$u_{n+p+1} = (a+b)u_{n+p} + ba^p \{(a+b)^n - u_n\},$$

as  $u_{n+p+1}$  includes, besides  $(a+b)u_{n+p}$ , those cases in which the last  $p$  trials are favourable, the one before unfavourable, and the  $n$  preceding containing no such run as stated.

We will not enter on Laplace's solution of this equation, or rather of one equivalent to it, especially as the result is not a simple one (see Todhunter, p. 185).

8. Let the probability of an event happening in one trial be  $p$ , that of its failing  $q$ ; we have seen (art. 4) that, if a large number  $N$  of trials be made, the event is most likely to happen  $pN$  times and fail  $qN$  times. The chance of this occurring is, however, extremely small, though greater than that in favour of any other proportion. We propose now to examine the probability that the proportion of successes shall not deviate from its most probable value by more than a given limit—that is, in fact, to find the probability that in  $N$  trials the number of times in which the event happens shall lie between the two limits  $pN \pm r$ .

Let  $m=pN$ ,  $n=qN$ , which are taken to be integers. The probability of the event happening  $m$  times is the greatest term  $T$  of the expansion (1), viz.,

$$T = \frac{N!}{m!n!} p^m q^n.$$

The calculation of this would be impracticable when  $N$ ,  $m$ ,  $n$  are large numbers, but Stirling's theorem gives us

$$1.2.3 \dots x = x^{x+\frac{1}{2}} e^{-x} \sqrt{2\pi},$$

very nearly, when  $x$  is large; and by substituting in the preceding value of  $T$ , and reducing, we easily find

$$T = \frac{1}{\sqrt{2\pi pqN}} \dots \dots \dots (8).$$

Now the terms of the expansion (1) on either side of  $T$  are

$$\dots \dots \frac{n(n-1)}{(m+1)(m+2)} \frac{p^2}{q^2} T + \frac{n}{m+1} \frac{p}{q} T + T + \frac{m}{n+1} \frac{q}{p} T + \frac{m(m-1)}{(n+1)(n+2)} \frac{q^2}{p^2} T + \dots \dots \dots (9).$$

But if  $x$  is much greater than  $a$ ,

$$x - a = xc^{-\frac{a}{x}} \text{ nearly,}$$

so that

$$n(n-1)(n-2) \dots (s \text{ terms}) = n^s e^{-\frac{1+2+\dots+(s-1)}{n}} = n^s e^{-\frac{s(s-1)}{2n}};$$

also

$$(m+1)(m+2) \dots (s \text{ terms}) = m^s e^{\frac{s(s+1)}{2m}}.$$

Hence the  $s$ th term before  $T$  in (9) is

$$\left(\frac{n}{m}\right)^s e^{-\frac{s(s-1)}{2n}} e^{-\frac{s(s+1)}{2m}} \left(\frac{p}{q}\right)^s T, \text{ or } e^{-\frac{Ns^2}{2mn} + \frac{m-n}{2mn} s} T.$$

The  $s$ th term after  $T$  is

$$e^{-\frac{Ns^2}{2mn} - \frac{m-n}{2mn} s} T.$$

Now the probability that the event shall happen a number of times comprised between  $m+r$  and  $m-r$  is the sum of the terms in (9) from the  $r$ th term before  $T$  to the  $r$ th term after  $T$ . (N.B., though  $r$  may be large, it is supposed small as compared with  $N$ ,  $m$ , or  $n$ .)

Now the  $s$ th term before  $T$  + the  $s$ th term after  $T = 2e^{-\frac{Ns^2}{2mn}} T$ ,

since  $e^x + e^{-x} = 2$ , when  $x = \frac{m-n}{2mn} s$  is small. Taking then each term before  $T$  with the corresponding term after  $T$ , and putting for shortness

$$a^2 = \frac{N}{2mn} = \frac{1}{2pqN} \dots \dots \dots (10).$$

we have for the required probability

$$p_r = 2\left(\frac{1}{2}T + Te^{-a^2} + Te^{-2a^2} + Te^{-3a^2} + \dots + Te^{-ra^2}\right).$$

If we now consider the curve whose equation is

$$y = Te^{-x^2},$$

and take a series of its ordinates corresponding to  $x=0, a, 2a, 3a, \dots, ra$ , where  $a$  is very small, and if  $A$  be its area from  $x=0$  to  $x=ra$ , then

$$\frac{A}{a} = \frac{1}{2}(\text{first} + \text{last ordinates}) + \text{sum of intermediate ordinates}$$

$$\therefore p_r = \frac{2}{a}A + \text{last ordinate},$$

$$= \frac{2}{a} \int_0^{ra} e^{-x^2} dx + Te^{-r^2 a^2}$$

or

$$p_r = \frac{2}{\sqrt{\pi}} \int_0^{ra} e^{-x^2} dx + \frac{1}{\sqrt{2pqN\pi}} e^{-r^2 a^2} \dots \dots (11).$$

9. We refer to the integral calculus for the methods of computing the celebrated integral  $\int e^{-x^2} dx$ , and will give here a short table of its values.

Table of the Values of the Integral  $I = \frac{2}{\sqrt{\pi}} \int_0^r e^{-x^2} dx$ .

$r$	$I$	$r$	$I$	$r$	$I$	$r$	$I$
0.00	0.00000	.2	.22270	1.3	.93401	2.4	.99931
.01	.01128	.3	.32863	1.4	.95229	2.5	.99959
.02	.02256	.4	.42839	1.5	.96611	2.6	.99976
.03	.03384	.5	.52050	1.6	.97635	2.7	.99986
.04	.04511	.6	.60386	1.7	.98379	2.8	.99992
.05	.05637	.7	.67780	1.8	.98909	2.9	.99996
.06	.06762	.8	.74210	1.9	.99279	3.0	.99998
.07	.07886	.9	.79691	2.0	.99532	$\infty$	1.00000
.08	.09008	1.0	.84270	2.1	.99702		
.09	.10128	1.1	.88020	2.2	.99814		
.1	.11246	1.2	.91031	2.3	.99886		

If the value of  $I$  is 0.5, or  $\frac{1}{2}$ ,  $r = .4769$ .

10. The second term in formula (11) expresses the probability that the number of occurrences of the event shall be exactly  $m+r$  or  $m-r$ , or more correctly the mean of these two probabilities. It may be neglected when the number of trials  $N$  is very great and the deviation  $r$  not a very small number.

We see from the foregoing table that when

$$ra = \frac{r}{\sqrt{2pqN}} = 3$$

it becomes practically a certainty that the number of occurrences will fall between the limits  $m \pm r$ .

Thus, suppose a shilling is tossed 200 times in succession; here  $p=q=\frac{1}{2}$  and  $a = \frac{1}{\sqrt{2pqN}} = \frac{1}{10}$ . If therefore  $r=30$ , it may be called a certainty that head will turn up more than 70 and less than 130 times.

In the same case suppose we wish to find the limits  $m \pm r$  such that it is an even chance that the number of heads shall fall between them, if the second term of (11) be neglected, we see from the table that

$$ra = \frac{1}{10} r = .48, \therefore r = 4.8;$$

so that the probability that the number of heads shall fall between 95 and 105 is

$$p_s = .52 + \frac{1}{10\sqrt{\pi}} e^{-\frac{1}{2}} = .57 \text{ nearly,}$$

rather more than an even chance.

11. Neglecting the second term of (11), we see that  $p_r$  depends solely on the value of  $ra$ , or that of  $\frac{r}{\sqrt{N}}$ ; so that, if the number of trials  $N$  be increased, the value of  $r$ , to give the same probability, increases as the square root of  $N$ ; thus, if in  $N$  trials it is practically certain (when  $ra=3$ ) that the number of occurrences lies between  $pN \pm r$ , then, if the number of trials be doubled, it will be certain that the occurrences will lie between  $2pN \pm r\sqrt{2}$ .

In all cases, if  $N$  be given,  $r$  can be determined, so that there is a probability amounting to certainty that the ratio of the number of occurrences to the whole number of cases shall lie between the limits

$$p \pm \frac{r}{N}.$$

Now if  $N$  be increased  $ra \propto \sqrt{N}$ ; so that these limits are

$$p \pm \frac{C}{\sqrt{N}},$$

$C$  being a constant. Hence it is always possible to increase the number of trials till it becomes a certainty that the proportion of occurrences of the event will differ from  $p$ , its probability on a single trial, by a quantity less than any assignable. This is the celebrated theorem given by James Bernoulli in the *Ars Conjectandi* (See Todhunter's *History*, p. 71.)

12. We will give here a graphical representation (Fig. 1), taken from M. Quetelet's *Lettres sur la Théorie des Probabilités*, of the facilities of the different numbers of successes which may occur in 1000 trials as to any event which is equally likely to happen as not in each trial,—as in 1000 tosses of a coin, or 1000 drawings from an urn containing one white and one black ball, replacing the ball each time,—or again in drawing 1000 balls together from an urn containing a great number of black and white in equal proportion.

As  $p=q=\frac{1}{2}$ , we find from formula (8) that the chance of exactly half the entire number drawn, viz., 500, being white is

$$T = \frac{1}{\sqrt{500\pi}} = 0.02523;$$

and the chance for any number  $500 \pm s$  is found by multiplying  $T$  by  $e^{-\frac{s^2}{500}}$ .

If then we take the central ordinate to represent  $T$  on any scale, and arrange along the horizontal line  $AB$  the different numbers of white balls which may occur, and erect opposite each number an ordinate representing the probability of that number, we have a graphical diagram of the relative possibilities of all possible proportions of black and white in the result.

We see from it that all values of the number of white balls drawn less than 450, or greater than 550, may be considered impossible, the probabilities for them being excessively small.

Fig. 1.

The probability of the number of white balls falling between any two assigned limits, as 450 and 550, is found by measuring the area of the figure comprised between the two ordinates opposite those numbers, and dividing the result by the total area.

## II. PROBABILITY OF FUTURE EVENTS DEDUCED FROM EXPERIENCE.

13. In our ignorance of the causes which influence future events, the cases are rare in which we know *a priori* the chance, or "facility," of the occurrence of any given event, as we do, for instance, that of a coin turning up head when tossed. In other cases we have to judge of the chances of it happening from experience alone. We could not say what is the chance that snow will fall in the month of March next from our knowledge of meteorology, but have to go back to the recorded facts. In walking down a certain street at 5 o'clock on three different days, I have twice met a certain individual, and wish to estimate from these data the likelihood of again meeting him under the same circumstances—in ignorance of the real state of things, viz., that he lives in that street, and returns from his business at that hour. Such is nearly the position in which we stand as to the probabilities of the future in the majority of cases.

We have to judge then, from certain recorded facts, of the probability of the causes which have occasioned them, and thence to deduce the probabilities of future events occurring under the operation of the same causes. The term "cause" is not here used in its metaphysical sense, but as simply equivalent to "antecedent state of things."

Let us suppose two urns,  $A$  containing two white balls,  $B$  containing one white and one black ball, and that a person not knowing which is which has drawn a white ball from one, to find the probability that this is the urn  $A$ . This is in fact to find, supposing a great number of such drawings to be made, what proportion of them have come from the urn  $A$ . If a great number  $N$  of drawings are made indiscriminately from both urns,  $\frac{1}{2}N$  come from the urn  $A$  and are all white,  $\frac{1}{2}N$  white come from the urn  $B$ , and  $\frac{1}{2}N$  black. The drawing actually made is either one of

the  $\frac{1}{2}N$  white from  $A$ , or of the  $\frac{1}{2}N$  white from  $B$ . As it is equally likely to have been any one of these, the chance that it came from  $A$  is  $\frac{1}{2}N \div \frac{1}{2}N$ , or  $\frac{1}{2}$ .

Suppose there had been two urns  $A$  and three urns  $B$ , and a white ball has been drawn from one of the five; as in a great number  $N$  of drawings  $\frac{2}{5}N$  come from  $A$  and are white,  $\frac{3}{5}N$  from  $B$  and  $\frac{1}{5}$  of them are white, the chance that it came from one of the urns  $A$  is

$$\frac{2}{5} \div (\frac{2}{5} + \frac{1}{5}) = \frac{2}{3}.$$

In general suppose an event to have occurred which must have been preceded by one of several causes, and let the antecedent probabilities of the causes be

$$P_1, P_2, P_3, \dots$$

and let  $p_1$  be the probability that when the first cause exists the event will follow,  $p_2$  the same probability when the second cause exists, and so on, to find, after the event has occurred, the probabilities of the several causes or hypotheses.

Let a great number  $N$  of trials be made; out of these the number in which the first cause exists is  $P_1N$ , and out of this number the cases in which the event follows are  $p_1P_1N$ ; in like manner the cases in which the second cause exists and the event follows are  $p_2P_2N$ ; and so on. As the event has happened, the actual case is one out of the number

$$(p_1P_1 + p_2P_2 + p_3P_3 + \dots)N,$$

and as the number in which the first cause was present is  $p_1P_1N$  the *a posteriori* probability of that cause is

$$\pi_1 = \frac{p_1P_1}{p_1P_1 + p_2P_2 + p_3P_3 + \dots} \quad (12).$$

So likewise for the other causes,—the sum of these *a posteriori* probabilities being

$$\pi_1 + \pi_2 + \pi_3 + \dots = 1.$$

Supposing the event to have occurred as above, we now see how the probability as to the future, viz., whether the event will happen or fail in a fresh trial, is affected by it. If the first cause exists, the chance that it will happen is  $p_1$ ; hence the chance of its happening from the first cause is  $p_1\pi_1$ ; so likewise for the second, third, &c. Hence the probability of succeeding on a second trial is

$$p_1\pi_1 + p_2\pi_2 + p_3\pi_3 + \dots \quad (13).$$

14. To give a simple example: suppose an urn to contain three balls which are white or black; one is drawn and found to be white. It is replaced in the urn and a fresh drawing made; find the chance that the ball drawn is white. There are three hypotheses, which are taken to be equally probable *a priori*, viz., the urn contains three white, two white, or one white,—that of none white being now impossible. The probability after the event of the first is by (12)

$$\frac{\frac{1}{3}}{\frac{1}{3} + \frac{1}{3} + \frac{1}{3}} = \frac{1}{3};$$

that of the second is  $\frac{1}{3}$ , that of the third  $\frac{1}{3}$ .

Hence the chance of the next drawing giving a white ball is

$$\frac{1}{3} \div (\frac{1}{3} + \frac{1}{3} + \frac{1}{3}) = \frac{1}{3}.$$

15. The calculations required in the application of formulas (12) and (13) are often tedious, and such questions may often be solved in a simpler manner. Let us consider the following:—

An urn contains  $n$  black or white balls. A ball is drawn and replaced; if this has been done  $r$  times, and in every case a white ball has appeared, to find the chance that the  $(r+1)$ th drawing will give a white ball.

If  $s$  drawings are made successively from an urn containing  $n$  balls, always replacing the ball drawn, the number of different ways this may be done is clearly  $n^s$ .

If there be  $n+1$  such urns, one with 0 white balls, one with 1 white, one with 2 white, &c., the last with  $n$  white, the whole number of ways in which  $r$  drawings can be made from any one of them is  $(n+1)n^r$ .

Now the number of ways in which  $r$  drawings, all white, can be made from the first is 0, from the second 1, from the third  $2^r$ , from the fourth  $3^r$ , and so on; so that the whole number of ways in which  $r$  drawings of a white ball can be made from the  $n+1$  urns is

$$1^r + 2^r + 3^r + \dots + n^r.$$

Hence the chance that if  $r$  drawings are made from an urn containing  $n$  black or white balls all shall be white is

$$P_r = \frac{1^r + 2^r + 3^r + \dots + n^r}{(n+1)n^r},$$

for all we know of the contents of such an urn is that they are equally likely to be those of any one of the  $n+1$  urns above.

If now a great number  $N$  of trials of  $r$  drawings be made from such urns, the number of cases where all are white is  $p_r N$ . If  $r+1$  drawings are made, the number of cases where all are white is  $p_{r+1} N$ ; that is, out of the  $p_r N$  cases where the first  $r$  drawings are white there are  $p_{r+1} N$  where the  $(r+1)$ th is also white; so that the probability sought for in the question is

$$= \frac{p_{r+1}}{p_r} = \frac{1}{n} \frac{1^{r+1} + 2^{r+1} + 3^{r+1} + \dots + n^{r+1}}{1^r + 2^r + 3^r + \dots + n^r}.$$

16. Let us consider the same question *when the ball is not replaced*. First suppose the  $n$  balls arranged in a row from A to B as below, the white on the left, the black on the right, the arrow marking the point of separation, which point is unknown (as it would be to a blind man), and is equally likely to be in any of its  $n+1$  possible positions.

Now if two balls, 1 and 2, are selected at random, the chance that both are white is the chance of the arrow falling in the division 2B of the row. But this chance is the same as that of a third ball 3 (different from 1 and 2), chosen at random, falling in 2B, — which chance is  $\frac{1}{3}$ , because it is equally probable that 1, 2, or 3 shall be the last in order. It is easy to see that these chances are the same if we reflect that, the ball 3 being equally likely to fall in A1, 12, or 2B, the number of possible positions for the arrow in each division always exceeds by 1 the number of positions for 3; therefore as 3 is equally likely to fall in any of the three divisions, so is the arrow.

The chance that two balls drawn at random shall both be white is thus  $\frac{1}{3}$ ; in the same way that for three balls is  $\frac{1}{4}$ , and so on. Hence the chance that  $r$  balls drawn shall all be white is

$$p_r = \frac{1}{r+1};$$

the same chance for  $r+1$  balls is

$$p_{r+1} = \frac{1}{r+2};$$

thus, as in a large number  $N$  of trials the number of cases where the first  $r$  drawn are white is  $p_r N$ , and the number where the first  $r+1$  are white is  $p_{r+1} N$ , we have the result:—

If  $r$  balls are drawn and all prove to be white, the chance that the next drawn shall also be white is

$$= \frac{p_{r+1}}{p_r} = \frac{r+1}{r+2}.$$

This result is thus independent of  $n$ , the whole number of balls. This result applies to repeated trials as to any event, provided we have really no *a priori* knowledge as to the chance of success or failure on one trial, so that all values for this chance are equally likely before the trial or trials. Thus, if we see a stranger hit a mark four times running, the chance he does so again is  $\frac{4}{5}$ ; or, if a person, knowing nothing of the water where he is fishing, draws up a fish each time in four casts of his line, the same is the chance of his succeeding a fifth time.<sup>1</sup>

In cases where we know, or rather think we know, the facility as to a single trial, if the result of a number of trials gives a large difference in the proportion of successes to failures from what we should anticipate, this will afford an appreciable presumption that our assumption as to the facility was erroneous, as indeed common sense indicates. If a coin turns up head twenty times running, we should say the two faces are probably not alike, or that it was not thrown fairly. We shall see later on, when we come to treat of the combination of separate probabilities as to the same event, the method of dealing with such cases (see art. 39).

We will give another example which may be easily solved by means of (12), or by the simpler process below.

There are  $n$  horses in a race, about which I have no knowledge except that one of the horses A is black; as to the result of the race I have only the information that a black horse has certainly won: to find the chance that this was A—supposing the proportion of black among racehorses in general to be  $p$ ; i.e., the probability that any given horse is black is  $p$ .

Suppose a large number  $N$  of trials made as to such a case. A wins in  $\frac{1}{n} N$  of these. Another horse B wins in  $\frac{1}{n} N$ ; out of these

<sup>1</sup> It may be asked why the above reasoning does not apply to the case of the chance of a coin which has turned up head  $r$  times doing so once more. The reason is that the antecedent probabilities of the different hypotheses are not equal. Thus, let a shilling have turned up head once; to find the chance of its doing so a second time. In formula (12) three hypotheses may be made as to a double—throw 1° two heads, 2° a head and tail, 3° two tails; but the probabilities of these are respectively  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{1}{4}$ ; therefore by (12) the probability of the 1st after the event is  $\frac{1}{4} \div (\frac{1}{4} + \frac{1}{2} + \frac{1}{4}) = \frac{1}{4}$ ; that of the second is also  $\frac{1}{4}$ ; and by (13) the probability of succeeding on a second trial is

$$\frac{\frac{1}{4} + \frac{1}{4}}{\frac{1}{4} + \frac{1}{2} + \frac{1}{4}} = \frac{1}{2},$$

because, if hypothesis 2° is the true one, the second trial must fail.

B is black in  $\frac{1}{n} N p$ . Likewise for C; and so on. Hence the actual case which has occurred is one out of the number

$$\frac{1}{n} N + \frac{n-1}{n} N p;$$

and, as of these the cases in which A wins are  $\frac{1}{n} N$ , the required chance that A has won is

$$\frac{1}{1 + (n-1)p}.$$

17. We now proceed to consider the important theorem of Bayes (see Todhunter, p. 294; Laplace, *Théorie Analytique des Prob.*, chap. 6), the object of which is to deduce from the experience of a given number of trials, as to an event which must happen or fail on each trial, the information thus afforded as to the real facility of the event in any one trial, which facility is identical with the proportion of successes out of an infinite number of trials, were it possible to make them.

Thus we find in the Carlisle Table of Mortality that of 5642 persons aged thirty 1245 died before reaching fifty; it becomes then a question how far we can rely on the real facility of the event, that is, the proportion of mankind aged thirty who die before fifty not differing from the ratio  $\frac{1245}{5642}$  by more than given limits of excess or defect. Again, it may be asked, if 5642 (or any other number of) fresh trials be made, what is the probability that the number of deaths shall not differ from 1245 by more than a given deviation?

The question is equivalent to the following:—An urn contains a very great number of black and white balls, the proportion of each being unknown; if, on drawing  $m+n$  balls,  $m$  are found white and  $n$  black, to find the probability that the proportion of the numbers in the urn of each colour lies between given limits.

The question will not be altered if we suppose all the balls ranged in a line AB (fig. 2), the white ones on the left, the black on the right, the point X where they meet being unknown and all positions for it in AB being *a priori* equally probable. Then,  $m+n$  points having been chosen at random in AB,  $m$  are found to fall on AX,  $n$  on XB. That is, all we know of X is that it is the  $(m+1)$ th in order beginning from A of  $m+n+1$  points chosen at random in AB. If we put AB=1, AX= $x$ , the number of cases when the point X falls on the element  $dx$ , is measured by

$$\frac{m+n}{m!n!} x^m (1-x)^n dx,$$

since for a specified set of  $m$  points, out of the  $m+n$ , falling on AX, the measure would be  $x^m (1-x)^n dx$ , and the number of such sets is  $\frac{m+n}{m!n!}$ . Now the whole number of cases is given by integrating this differential from 1 to 0; and the number in which X falls between given distances  $\alpha, \beta$  from A is found by integrating from  $\beta$  to  $\alpha$ . Hence the probability that the ratio of the white balls in the urn to the whole number lies between any two given limits  $\alpha, \beta$  is

$$p = \frac{\int_{\alpha}^{\beta} x^m (1-x)^n dx}{\int_0^1 x^m (1-x)^n dx} \dots \dots \dots (14).$$

The curve of frequency for the point X after the event—that is, the ordinate of which at any point of AB is proportional to the frequency or density of the positions of X in the immediate vicinity of that point—is

$$y = x^m (1-x)^n;$$

the maximum ordinate KV occurs at a point K, dividing AB in the ratio  $m:n$ ,—the ratio of the total numbers of white and black balls being thus more likely to be that of the numbers of each actually drawn than any other.

Let us suppose, for instance, that three white and two black have been drawn; to find the chance that the proportion of white balls is between  $\frac{2}{5}$  and  $\frac{3}{5}$  of the whole; that is, that it differs by less than  $\pm \frac{1}{5}$  from  $\frac{3}{5}$ , its most natural value.

$$p = \frac{\int_{\frac{2}{5}}^{\frac{3}{5}} x^3 (1-x)^2 dx}{\int_0^1 x^3 (1-x)^2 dx} = \frac{2256}{5^5} = \frac{18}{25} \text{ nearly.}$$

18. An event has happened  $m$  times and failed  $n$  times in  $m+n$  trials. To find the probability that in  $p+q$  further trials it shall happen  $p$  times and fail  $q$  times,—that is, that,  $p+q$  more points

being taken at random in AB,  $p$  shall fall in AX and  $q$  in XB. The whole number of cases is measured by

$$(AB)^{r+n} = \frac{(r+n)!}{r!n!} \int_0^1 x^r (1-x)^n dx = \frac{(r+n)!}{r!n!} \int_0^1 x^n (1-x)^r dx.$$

The number of favourable cases, when any particular set of  $p$  points, out of the  $p+q$  additional trials, falls in AX, is measured by

$$\frac{(r+n)!}{r!n!} \int_0^1 x^{r-p} (1-x)^{n-p} dx,$$

because, the number of cases as to the  $r+n$  points being, when X falls on the element  $dx$ ,

$$\frac{(r+n)!}{r!n!} x^r (1-x)^n dx,$$

each of these affords  $x^{r-p} (1-x)^{n-p}$  cases where  $p$  new points fall on AX, and  $q$  on XB.

Now, the number of different sets of  $p$  points being

$$\frac{(p+q)!}{p!q!},$$

the required probability is

$$= \frac{(p+q)!}{p!q!} \frac{\int_0^1 x^{r-p} (1-x)^{n-p} dx}{\int_0^1 x^r (1-x)^n dx} \dots (15);$$

or, by means of the known values of these definite integrals,

$$= \frac{(p+q)!}{p!q!} \frac{(r+n-p)!}{(r+n)!} \frac{(r+n)!}{(r+n-p)!} \frac{(r+n-p)!}{(r+n-p)!} \dots (16).$$

For instance, the chance that in one more trial the event shall happen is  $\frac{r+1}{r+n+1}$ . This is easy to verify, as the line AB has been divided into  $r+n+2$  sections by the  $r+n+1$  points taken on it (including X). Now if one more trial is made, i.e., one more point taken at random, it is equally likely to fall in any section; and  $r+1$  sections are favourable.

19. When the number of trials  $r+n$  in art. 17 is large, the probability is considerable that the facility of the event on a single trial will not differ from its most natural value, viz.,  $\frac{r}{r+n}$  by more than a very small deviation. To make this apparent, we shall have to modify the formula (14), which gives for the chance that this facility lies between the limits  $\alpha$  and  $\beta$  (by substituting for the denominator its known value),

$$p = \frac{(r+n-1)!}{r!n!} \int_0^1 x^r (1-x)^n dx \dots (17).$$

To find now the probability that the facility lies between the limits  $\beta = \frac{r}{r+n} + \delta$ , and  $\alpha = \frac{r}{r+n} - \delta$ , where  $\delta$  is small. Put for  $x$ ,  $\frac{r}{r+n} + \delta$ ; and (17) becomes

$$p = \frac{(r+n-1)!}{r!n!} \int_{-\delta}^{\delta} \left( \frac{r}{r+n} + \delta \right)^r \left( \frac{n}{r+n} - \delta \right)^n dx.$$

Now if  $\delta$  is small, and we put  $u = (a + x)^r$ ,

$$\log u = r \log a + r \frac{x}{a} - \frac{rx^2}{2a^2}$$

$$\therefore u = a^r e^{\frac{rx}{a} - \frac{rx^2}{2a^2}}$$

correct as far as the square of  $x$ . Hence the two factors under the sign of integration become

$$\frac{r!}{(r+n)!} e^{(r+n)x} = \frac{(r+n)!}{r!n!} e^{-\frac{(r+n)x^2}{2n}}, \text{ and } \frac{n!}{(r+n)!} e^{-(r+n)x} = \frac{(r+n)!}{r!n!} e^{-\frac{(r+n)x^2}{2n}};$$

so that

$$p = \frac{(r+n-1)!}{r!n!} \frac{r!n!}{(r+n)!} \int_{-\delta}^{\delta} e^{-\frac{(r+n)x^2}{2n}} dx \dots (18).$$

Now, since by Stirling's theorem  $|n| = r^{r-1} e^{-r} \sqrt{2\pi r}$ , the constant coefficient here becomes

$$\frac{(r+n-1)!}{r!n!} \frac{r!n!}{(r+n)!} = \frac{(r+n)!}{r!n!} \frac{r!n!}{(r+n)!} = \frac{(r+n)!}{\sqrt{2\pi n r}},$$

taking  $m+n+1 = r+n$ . Now if we substitute in (18)

$$t = x \frac{(r+n)!}{\sqrt{2\pi n r}} \dots (19),$$

$$p = \frac{1}{\sqrt{\pi}} \int_{-\lambda}^{\lambda} e^{-t^2} dt,$$

where

$$\lambda = \frac{(m+n)!}{\sqrt{2\pi n r}} \dots (20),$$

or finally

$$p = \frac{2}{\sqrt{\pi}} \int_0^{\lambda} e^{-t^2} dt \dots (21),$$

for the approximate value of the probability that the real facility of the event lies between the limits  $\frac{r}{r+n} \pm \delta$ .

Thus, if out of 10,000 trials, the event has happened 5000 times, the probability that, out of an infinite number, the number of successes shall lie between  $\frac{1}{2} \pm \frac{1}{10}$ , or between  $\frac{49}{100}$  and  $\frac{51}{100}$ , of the whole, will be

$$p = .678 = \frac{2}{3} \text{ nearly,}$$

for we find from (20)  $\lambda = \frac{10^4}{\sqrt{2\pi} \cdot 5000} = .7$  nearly; and, referring to the table in art. 9, we find the above value for the integral (21).

We must refer to the sixth chapter of Laplace for the investigation of how far the number of successes in a given number of fresh trials may be expected to deviate from the natural proportion, viz., that of the observed cases—as also for several closely allied questions, with important applications to statistics.

### III. ON EXPECTATION.

20. The value of a given chance of obtaining a given sum of money is the chance multiplied by that sum; for in a great number of trials this would give the sum actually realized. The same may be said as to loss. Thus if it is 2 to 1 that a horse will win a race, it is considered a fair wager to lay £10 to £20 on the result; for the value of the expected gain is  $\frac{2}{3}$  of 10, and that of the expected loss  $\frac{1}{3}$  of 20, which are equal. Thus, if the probabilities for and against an event are  $p$ ,  $q$ , and I arrange in any way to gain a sum  $a$  if it happens and lose a sum  $b$  if it fails, then if  $pa = qb$  I shall neither gain nor lose in the long run; but if the ratio  $a : b$  be less than this, my expectation of loss exceeds that of gain; or, in other words, I must lose in the long run.

The above definition is what is called the *mathematical expectation*; but it clearly is not a proper measure of the advantage or loss to the individual; for a poor man would undoubtedly prefer £500 down to the chance of £1000 if a certain coin turns up head. The importance of a sum of money to an individual, or its *moral value*, as it has been called, depends on many circumstances which it is impossible to take into account; but, roughly and generally, there is no doubt that Daniel Bernoulli's hypothesis, viz., that this importance is measured by the sum divided by the *fortune of the individual*—is a true and natural one. Thus, generally speaking, £5 is the same to a man with £1000 as £50 to one with £10,000; and it may be observed that this principle is very generally acted on, in taxation, &c.

21. To estimate, according to this hypothesis, the advantage or moral value of his whole fortune to the individual, or his *moral fortune*, as Laplace calls it, in contradistinction to his *physical fortune*, let  $x$  = his physical fortune,  $y$  = his moral fortune, then, if the former receive an increment  $dx$ , we have, from Daniel Bernoulli's principle,

$$dy = k \frac{dx}{x};$$

$$\therefore y = k \log \frac{x}{h} \dots (22),$$

$k$ ,  $h$  being two constants.  $x$  and  $y$  are always positive, and  $x > h$ ; for every man must possess some fortune, or its equivalent, in order to live.

22. To estimate now the value of a *moral expectation*. Suppose a person whose fortune is  $a$  to have the chance  $p$  of obtaining a sum  $\alpha$ ,  $q$  of obtaining  $\beta$ ,  $r$  of obtaining  $\gamma$ , &c., and let

$$p+q+r+\dots=1,$$

only one of the events being possible. Now his moral expectation from the first chance—that is, the increment of his moral fortune into the chance—is

$$p \left\{ \log \frac{a+\alpha}{h} - \log \frac{a}{h} \right\} = p \log(a+\alpha) - p \log a$$

Hence his whole moral expectation is

$$E = kp \log(a+\alpha) + kq \log(a+\beta) + kr \log(a+\gamma) + \dots - k \log a;$$

This rule must be understood to hold only when the sum is very small, or rather infinitesimal, strictly speaking. It would lead to absurdities if it were used for large increments (though Buffon has done so; see Todhunter, p. 345). Thus, to a man possessing £100, it is of the same importance to receive a gift of £100 as two separate gifts of £50; but this rule would give as the measure of the importance of the first gift 1; while in the other case, it would give  $\frac{1}{2}$ . The real measure of the importance of an increment when not small is a matter for calculation, as shown in the text.

It is important to remark that we should be wrong in thus adding the expectations if the events were not mutually exclusive. For the mathematical expectations it is not so.

and, if  $Y$  stands for his moral fortune including this expectation, that is,  $k \log \frac{a}{h} + E$ , we have

$$Y = k p \log(a + a) + k q \log(a + \beta) + \dots - k \log h. \quad (23).$$

Let  $X$  be the physical fortune corresponding to this moral one, by (22)

$$Y = k \log X - k \log h.$$

Hence  $X = (a + a)^p (a + \beta)^q \dots$  (24); and  $X - a$  will be the actual or physical increase of fortune which is of the same value to him as his expectation, and which he may reasonably accept in lieu of it.

The mathematical value of the same expectation is

$$p a + q \beta + r \gamma + \dots \quad (25).$$

23. Several results follow from (24). Thus, if the sums  $a, \beta, \gamma, \dots$  are very small, it is easy to see that the moral expectation coincides with the mathematical, for

$$X = a^{p+q+\dots} \left(1 + \frac{a}{a}\right)^p \left(1 + \frac{\beta}{a}\right)^q \dots = a^{p+q+\dots} \left(1 + p \frac{a}{a} + q \frac{\beta}{a} + \dots\right);$$

$$\therefore X = a + p a + q \beta + \dots$$

24. We may show also that it is disadvantageous to play at even a fair game of chance (unless the stakes are very small, in which case the last article applies). Thus, suppose a man whose fortune is  $a$  plays at a game where his chance of winning a sum  $\alpha$  is  $p$ , and his chance of losing a sum  $\beta$  is  $q = 1 - p$ . If the game is fair,

$$p \alpha = q \beta.$$

Now by (24) the physical fortune which is equivalent to his prospects after the game is

$$X = (a + \alpha)^p (a - \beta)^q,$$

$$\text{or} \quad X = (a + \alpha)^{\frac{p}{a+\alpha}} (a - \beta)^{\frac{q}{a-\beta}}.$$

Now the geometrical mean of  $r$  quantities is less than the arithmetical,<sup>1</sup> so that if there are  $\beta$  quantities  $a + \alpha$ , and  $\alpha$  quantities  $a - \beta$ ,

$$\left\{ (a + \alpha)^\beta (a - \beta)^\alpha \right\}^{\frac{1}{\alpha+\beta}} < \frac{\beta(a + \alpha) + \alpha(a - \beta)}{\alpha + \beta},$$

or  $X < a$ , so that he must expect morally to lose by the game.

25. The advantage of insurance against risks may be seen by the following instance. A merchant, whose fortune is represented by 1, will realize a sum  $\epsilon$  if a certain vessel arrives safely. Let the probability of this be  $p$ . To make up exactly for the risk run by the insurance company, he should pay them a sum

$$(1 - p)\epsilon.$$

If he does, his moral fortune becomes by (22)

$$k \log \frac{1 + p\epsilon}{h};$$

while, if he does not insure, it will be (23).

$$k p \log \frac{1 + \epsilon}{h}.$$

Now the first of these exceeds the second, so that he gains by insuring on these terms; because

$$\log(1 + p\epsilon) > p \log(1 + \epsilon),$$

$$\text{that is} \quad (1 + p\epsilon)^{\frac{1}{p}} > 1 + \epsilon;$$

for, putting  $p = \frac{m}{m+n}$ ,

$$\left( \frac{m(1 + \epsilon) + n}{m + n} \right)^{m+n} > (1 + \epsilon)^m,$$

because (see note art. 24), if  $m(1 + \epsilon) + n$  is divided into  $m + n$  equal parts, their product is greater than that of  $m$  parts each equal to  $1 + \epsilon$  and  $n$  parts each equal to 1.

The merchant will still gain by paying, over and above what covers the risk of the company, a sum  $\alpha$ , at most, which satisfies

$$\log(1 - \alpha + p\epsilon) = p \log(1 + \epsilon);$$

$$\therefore \alpha = 1 + p\epsilon - (1 + \epsilon)^p.$$

By paying any sum not exceeding this value, he still gains, while

<sup>1</sup> A very simple proof of this principle is as follows:—let a number  $N$  be divided into  $r$  parts  $a, b, c, \dots$ ; if any two of these, as  $a, b$ , are unequal, since  $\left(\frac{a+b}{2}\right)^2 > ab$ ,

it follows that the product  $a \cdot b \cdot \dots$  is increased by substituting  $\frac{a+b}{2}, \frac{a+b}{2}$ , for  $a$  and  $b$ . Hence as long as any two are unequal we can divide  $N$  differently so as to obtain a greater product; and therefore when the parts are all equal the product is greatest, or

$$\left( \frac{a+b+c+\dots}{r} \right)^r > abc \dots$$

the insurance office also makes a profit, which is really a certainty when it has a large business; so that, as Laplace remarks, this example explains how such an office renders a real service to the public, while making a profit for itself. In this it differs from a gambling establishment, in which case the public must lose, in any sense of the term.

It may be shown that it is better to expose one's fortune in separate sums to risks independent of each other than to expose the whole to the same danger.<sup>2</sup> Suppose a merchant, having a fortune  $a$ , has besides a sum  $\epsilon$  which he must receive if a ship arrives in safety. By (24) the value in money of his present fortune is

$$X = (a + \epsilon)^p a^q,$$

where  $p$  = chance of the ship arriving, and  $q = 1 - p$ .

Now suppose he risks the same sum in two equal portions, in two ships. We cannot apply (23), as the events are not mutually exclusive; but we see that, if both ships arrive, the chance of this being  $p^2$ , he realizes the whole sum  $\epsilon$ ; if one only arrives, the chance being  $2pq$ , he receives  $\frac{1}{2}\epsilon$ ; if both are lost, the chance being  $q^2$ , he loses all. Thus (24) he is now worth a sum

$$X' = (a + \epsilon)^{p^2} (a + \frac{1}{2}\epsilon)^{2pq} a^{q^2}.$$

Now this sum is greater than the former; for

$$(a + \epsilon)^{p^2 - p} (a + \frac{1}{2}\epsilon)^{2pq} a^{q^2 - q} > 1,$$

that is,

$$(a + \epsilon)^{-pq} (a + \frac{1}{2}\epsilon)^{2pq} a^{-pq} > 1;$$

for

$$\frac{(a + \frac{1}{2}\epsilon)^2}{a(a + \epsilon)} > 1,$$

as is obviously true.

Now suppose he risks the sum  $\epsilon$  in three separate ventures. His fortune will be

$$X'' = (a + \epsilon)^{p^3} (a + \frac{2}{3}\epsilon)^{3p^2q} (a + \frac{1}{3}\epsilon)^{3pq^2} a^{q^3};$$

and we have to show that this is worth more than when there were two. If we put  $a$  outside each bracket, and put  $\delta = \frac{\epsilon}{3a}$  we have to prove

$$(1 + 3\delta)^{p^3} (1 + 2\delta)^{3p^2q} (1 + \delta)^{3pq^2} > (1 + 3\delta)^{p^2} (1 + \frac{2}{3}\delta)^{2pq};$$

$$\text{or} \quad (1 + 3\delta)^{p^2 - p} (1 + 2\delta)^{3pq} (1 + \delta)^{3q^2} > (1 + \frac{2}{3}\delta)^{2q};$$

or, since  $p^2 - p = -pq$ ,

$$(1 + 3\delta)^{-p} (1 + 2\delta)^{3pq} (1 + \delta)^{3q} > (1 + \frac{2}{3}\delta)^2,$$

$$\text{or} \quad \left\{ \frac{(1 + 2\delta)^3}{(1 + 3\delta)(1 + \delta)^2} \right\}^p (1 + \delta)^3 > (1 + \frac{2}{3}\delta)^2;$$

now

$$(1 + 2\delta)^3 < (1 + \delta)^3 (1 + 3\delta);$$

hence the fraction in the brackets is always less than its  $p$ th power as  $p < 1$ ; and we can now show that

$$\frac{(1 + 2\delta)^3}{(1 + 3\delta)(1 + \delta)^2} (1 + \delta)^3 > (1 + \frac{2}{3}\delta)^2,$$

that is,

$$(1 + 2\delta)^3 > (1 + 3\delta)(1 + \frac{2}{3}\delta)^2,$$

or

$$1 + 6\delta + 12\delta^2 + 8\delta^3 > 1 + 6\delta + \frac{4}{3}\delta^2 + \frac{2}{3}\delta^3.$$

Laplace shows (ch. x.) that the gain continues to increase by subdivision of the risk; it could no doubt be shown by ordinary algebra. He shows further that the moral advantage tends to become equal to the mathematical. This may be done more easily thus:—

The expression is, when  $\epsilon$  is divided into  $r$  equal parts,

$$X = (a + \epsilon)^p \left( a + \epsilon - \frac{\epsilon}{r} \right)^{rp^{r-1}q} \left( a + \epsilon - \frac{2\epsilon}{r} \right)^{\frac{r(r-1)}{2} p^{r-2} q^2} \dots$$

and we have to find the limit towards which this tends as  $r$  becomes infinitely great.

Put  $z = a + \epsilon$ ;

$$X = z^p \left( z - \frac{\epsilon}{r} \right)^{rp^{r-1}q} \left( z - \frac{2\epsilon}{r} \right)^{\frac{r(r-1)}{2} p^{r-2} q^2} \dots \left( z - \frac{(r-1)\epsilon}{r} \right)^{r q^{r-1} p} \left( z - \epsilon \right)^{q^r}$$

Now in the binomial expansion

$$1 = p^r + r p^{r-1} q + \frac{r(r-1)}{1 \cdot 2} p^{r-2} q^2 + \dots$$

the greatest term is the  $(qr + 1)$ th, viz.,

$$T = \frac{r(r-1) \dots (rp+1)}{1 \cdot 2 \cdot 3 \dots r q} p^r q^r.$$

The factor in  $X$  corresponding to this is

$$\left( z - r q \frac{\epsilon}{r} \right)^T = U^T,$$

if we put  $U = z - q\epsilon$ .

Let us now express the binomial series before and after  $T$  thus:

$$1 = \dots + T_3 + T_2 + T_1 + T + t_1 + t_2 + t_3 + \dots$$

<sup>2</sup> The familiar expression not to "put all one's eggs in the same basket" shows us how general common sense has recognized this principle.

and we have

$$\bar{X} = \dots \left(1 - \frac{e}{p}\right)^2 \left(1 + \frac{e}{p}\right)^2 \left(1 - \frac{e}{p}\right)^2 \left(1 + \frac{e}{p}\right)^2 \dots$$

The factors towards the beginning and end may be all taken as 1, because the terms of the binomial increase rapidly in value from either end when  $n = \infty$ , and we shall have the true limit for  $\bar{X}$  by taking an indefinitely great number of factors on either side of  $1$ , which number, however, may be indefinitely less than  $n$ .

As the  $n$ th factor before and after  $1$  may be expressed since  $e$  being always very small compared to  $p$ ,—

$$\left(1 - \frac{e}{p}\right)^2, \left(1 + \frac{e}{p}\right)^2,$$

and as  $\dots \bar{X}_2 \bar{X}_1 \bar{X}_0 \dots = 1$ , we have

$$\bar{X} = \sqrt[p]{\bar{X}_2 \bar{X}_1 \bar{X}_0 \dots \bar{X}_{-1} \bar{X}_{-2} \dots}$$

Now we have seen in art. 3 that

$$\bar{X}_1 = 1 - \frac{e}{p} \frac{p-q}{p}, \quad \bar{X}_0 = 1 - \frac{e}{p} \frac{p-q}{p},$$

$$\text{Hence} \quad \bar{X}_1 - \bar{X}_0 = 1 - \frac{e}{p} \frac{p-q}{p} - \left(1 - \frac{e}{p} \frac{p-q}{p}\right);$$

$$\therefore \bar{X}_1 - \bar{X}_0 = \frac{p-q}{p} \frac{e}{p} = \frac{e}{p^2}.$$

Hence the exponent of  $e$  above becomes

$$\frac{e}{p} \cdot \frac{1}{p^2} = \sum_{k=0}^{\infty} \frac{e}{p^2} = \frac{e}{p^2} \cdot \frac{1}{1 - \frac{e}{p}},$$

$e$  being the extreme limit for  $X$ .

$$\text{If we put } r = \frac{e}{p}, \text{ and } \frac{e}{p^2} = \phi(r),$$

the above sum is

$$\phi(r) = r \left( \frac{1}{p} \right) + r \left( \frac{2}{p} \right) + \dots + r \left( \frac{n}{p} \right) = r \int_0^1 \frac{1}{1-rx} dx.$$

Now it is easy to prove that

$$\int_0^1 \frac{1}{1-rx} dx \text{ is finite;}$$

and much more is so when the exponent limit is finite.

Hence the exponent of  $e$  becomes

$$\frac{e}{p^2} \frac{1}{1 - \frac{e}{p}} = \frac{e}{p^2} \cdot \frac{1}{1 - \frac{e}{p}} = \frac{e}{p^2} \cdot \frac{1}{1 - r},$$

where  $\bar{X}$  is finite; so that the exponent becomes infinitesimal when  $n = \infty$ .

The limit therefore towards which  $\bar{X}$  tends is

$$\bar{X} = 1 - \frac{e}{p} = 1 - r,$$

that is the mathematical value of the formula.

The very important applications of probability to statistics and insurance are to be found in the articles on those subjects, on which therefore we refer the reader.

#### IV. FUNDAMENTALS OF TESTIMONY.

24. We have here to treat of the probability of events asserted by several witnesses of known credibility, or which have several different probabilities in their favour, derived from different independent sources of information of any kind, of known value.

A witness may tell in two ways: he may be intentionally dishonest, or he may be mistaken: his evidence may be false, either because he wishes to deceive, or because he is deceived himself. However, we will not here take separate account of these two sources of error, but sum up under the probability of the truth of a statement made by a witness, which will be a true measure of the value of his evidence. To estimate this probability in any given case is not an easy matter: but if we could examine a large number of statements made by a certain person, and find in how many of them he was right, the ratio of these numbers would give the probability that any statement of his, taken as we find, whether true or false, is a true one.

25. Suppose a witness, whose credibility is  $p$ , states that a fact occurred or did not occur, or that an event turned out in one way, when only two ways are possible. If nothing was known *a priori* as to the probability of the fact, or if the real facting was  $\frac{1}{2}$ , it is clear that the probability that it did occur is  $p$ . For if a great

number  $N$  of trials were made, either really as to the event, or the facting is known to be  $\frac{1}{2}$ , as in testing a coin, or as to facting only cases resembling it as to one instance of the real facting, it will be the state of things, in  $\frac{1}{2}N$  the event happened, and out of these the witness asserts in  $\frac{1}{2}pN$  cases that it did happen. Now, out of the whole number, he asserts in  $\frac{1}{2}pN$  cases that it happened, whereas there is no reason for his asserting otherwise than he did not. It may be said he asserts in  $\frac{1}{2}pN$  cases that it did happen, and in  $\frac{1}{2}(1-p)N$  cases that it did not. Hence dividing the whole number of cases when it happened and the assertion is by the whole number of cases when he asserts in we find  $\frac{1}{2}pN \div \frac{1}{2}N = p$ .

We have entered at length on the proof of what is almost self-evident, perhaps indeed included in the definition, in this case, because the same method will succeed in other cases which are not so easily to be discerned.

26. Let us now consider the same question when the *a priori* probability of the fact or event is known. Suppose a bag contains  $n$  balls, one white and the rest black, and the same witness says he has seen the white ball drawn; what is the chance that it was drawn?

A great number  $N$  of trials being made, the number in which the white ball is drawn is  $\frac{1}{n}N$ , and out of these he asserts in  $\frac{1}{n}pN$  cases. One of the remaining  $(1 - \frac{1}{n})N$  cases where a black ball was drawn he says wrongly, that it is  $1 - \frac{1}{n}$ ,  $(1 - \frac{1}{n})N$  cases it was white.

Now, dividing the number of favourable cases, viz. those where he says it is white and it is so, by the whole number of cases, viz. those where he says it is white, we have for the probability required

$$= \frac{\frac{1}{n}pN}{\frac{1}{n}pN + (1 - \frac{1}{n})N} = \frac{p}{p + (1 - \frac{1}{n})(1 - p)} \dots 26.$$

This holds for any event where *a priori* probability is  $\frac{1}{n}$ .

If  $n$  be very large, this probability will be very small, unless  $p$  is nearly  $= 1$ ; and indeed if we go back to the common sense view, it is clear we should hesitate to believe a man who said he had drawn the white ball from a bag containing 1,000 balls all but 1 being black. It may be observed that if  $n = 2$ ,  $n = p$ , as in art. 25.

We have thus a scientific explanation of the universal verdict of juries to reject the evidence of a witness that he asserts the truth of a fact asserted by him, when it is in itself of an extraordinary or very improbable nature.

27. Two independent witnesses,  $A$  and  $B$ , both state a fact or that an event turned out in a particular way (only two ways being possible), to find the probability of the truth of the statement.

Supposing nothing is known *a priori* as to the event in question, let a great number  $N$  of trials be made as to each event: the number of true events will be  $\frac{1}{2}N$ ; one of these the witness  $A$  asserts the stories in  $\frac{1}{2}pN$  cases; one of these the witness  $B$  asserts in, too, in  $\frac{1}{2}pN$  cases. One of the  $\frac{1}{2}N$  failures  $A$  asserts a success in  $\frac{1}{2}(1-p)N$  cases; and one of these  $B$  also asserts one in  $\frac{1}{2}(1-p)N$  cases. Hence dividing the favourable cases by the whole number, the probability sought is

$$= \frac{\frac{1}{2}pN}{\frac{1}{2}pN + \frac{1}{2}(1-p)N} = \frac{p}{p + (1-p)} \dots 27.$$

where  $p, p'$  are the credibilities of the two witnesses.

This very important result also holds if  $p$  be the probability of the event derived from any source, and  $p'$  the credibility of one witness, as in art. 26; or if  $p$  and  $p'$  be any independent probabilities derived from any sources, as in one event.

28. We give another method of establishing the formula 27. Referring to art. 13, the observed event is the occurrence of evidence of  $A$  and  $B$  that a statement is true. There are two hypotheses—what it is true or false. According to  $B$  evidence the probabilities of these hypotheses are  $p$  and  $1-p$  (art. 26), as  $A$  has said that it is true. The observed event now is that  $B$  says the same. On the first hypothesis the probability that he will say this is  $p'$ ; on the second it is  $1-p'$ . Hence by formula 16, the probability *a posteriori* of the first hypothesis, viz. that the first statement is true, is as before,

$$\frac{p p'}{p p' + (1-p)(1-p')}.$$

29. If a third witness, whose credibility is  $p''$ , occurs with the two former, we shall have to combine  $p''$  with  $p$  in formula 26; hence the probability of the statement when made by three witnesses is

$$= \frac{p p p'}{p p p' + (1-p)(1-p')(1-p'')} \dots 28;$$

and so on for any number.

30. Here we are assuming the independence of the witnesses. If  $A$  &  $B$  are never discordant in favour of the statement or if  $A$  &  $B$  are never discordant in favour of the statement in more than  $\frac{1}{2}N$  cases.

As an example, let us find how many witnesses to a fact, the odds against which are 1,000,000,000 to 1, would be required to make it an even chance that the fact did occur, supposing the credibility of each witness to be  $p = \frac{9}{10}$ .

Let  $x$  be the number.

$$\frac{1}{2} = \frac{10^{-12} p^x}{10^{-12} p^x + (1 - 10^{-12})(1 - p)^x} = \frac{p^x}{p^x + 10^{12}(1 - p)^x};$$

$$\therefore 2 = 1 + \frac{10^{12}}{p^x};$$

$$\therefore x = \frac{12}{\log 9} = 12.6;$$

so that thirteen such witnesses would render the chance more than an even one.

32. Let us now consider an event which may turn out in more than two ways, and let each way be equally probable *a priori*, and suppose a witness whose credibility is  $p$  states that it turned out in a certain way; what is the chance that it did so?

Thus if a die has been thrown, and he states that ace turned up; or if tickets in a lottery are numbered 1, 2, 3, &c., and he states that 1 was drawn; to find the chance that he is right.

Take the case of the die, and suppose a great number  $N$  of throws. In  $\frac{1}{6}N$  the ace turns up, and he says so in  $\frac{1}{6}pN$  cases. In  $\frac{1}{6}N$  the two turns up, and he is wrong in  $\frac{1}{6}(1 - p)N$  cases out of these; but he says ace in only  $\frac{1}{6}$  of these, as there is no reason why he should give it more or less often than any of the five wrong numbers. In the same way for the other throws; so that the whole number of cases where he says ace turned up is

$$\frac{1}{6}pN + \frac{1}{6}(1 - p)N = \frac{1}{6}N;$$

and, the number, out of these, when it actually turned up being  $\frac{1}{6}N$ , we find the chance it did turn up is  $p$ , the credibility of the witness. In any such case, this result will hold. We might indeed safely have argued that when the die is thrown a great number of times, any witness, whatever his veracity, will quote each face as often as any other, as there is no reason for one to turn up oftener than another, nor for him to affirm, rightly or wrongly, one rather than another; so that he will say ace in  $\frac{1}{6}N$  of the throws, while he says ace in  $\frac{1}{6}pN$  out of the  $\frac{1}{6}N$  cases where it does turn up.

This result compared with art. 28 affords an apparent paradox. If a large number of tickets are marked 1, 0, 0, 0, 0 . . . and a witness states that 1 has been drawn from the bag, we see from art. 28 that the chance he is right is very small; whereas if the tickets were marked 1, 2, 3, 4, 5, 6 . . . and he states that 1 has been drawn, the chance he is right is  $p$ , his own credibility. However, we must remember that in the first case he is limited to two statements, 1 and 0, and he makes the first, which is very improbable in itself; whereas in the other case, the assertion he makes is in itself as probable as any other he can make—*e.g.*, that 2 was the ticket drawn—and therefore our expectation of its truth depends on his own credibility only.

33. Suppose now that two witnesses A, B both assert that the event has turned out in a certain way, there being, as in art. 32,  $n$  equally probable ways.

Both, for instance, say that in a lottery numbered 1, 2, 3, 4, 5 . . . No. 1 has been drawn. A large number  $N$  of drawings being made, 1 is drawn in  $n^{-1}N$  cases; out of these A says 1 in  $n^{-1}pN$  cases, and out of these B also says 1 in  $n^{-1}ppN$ . No. 2 is drawn in  $n^{-1}N$  cases; here A is wrong in  $n^{-1}(1 - p)N$ , but says 1 in only  $(n - 1)^{-1}n^{-1}(1 - p)N$ ; and B will also say 1 in  $(1 - p')(n - 1)^{-1}$  of these; that is, both agree that 1 has been drawn in

$$(n - 1)^{-2}n^{-1}(1 - p)(1 - p')N$$

cases. So likewise if No. 3 has been drawn, and so on; hence, when No. 1 has not been drawn, they both say that it has in

$$n^{-1}(n - 1)^{-1}(1 - p)(1 - p')N$$

cases. Hence the number of cases where they are right divided by the whole number of cases where they make the statement, that is, the probability that No. 1 has been drawn, is

$$\frac{pp'}{pp' + (n - 1)^{-1}(1 - p)(1 - p')} \quad \dots (29).$$

If  $n$  be a large number the chance that they have named the ticket drawn is nearly certainty. Thus, if two independent witnesses both select the same man out of a large number, as the one they have seen commit a crime, the presumption is very strong against him. Of course, for the case to come under the above formula, it is supposed that some one of the number must be guilty.

34. In the same case, when the event may turn out in  $n$  ways not equally probable, as in a race between  $n$  horses A, B, C . . . whose chances of winning are  $a, b, c, \dots$ , so that  $a + b + c + \dots = 1$ , if one witness whose credibility is  $p$  states that A has won, it is

easily shown by the same reasoning as in art. 33 that the probability A has really won is

$$\frac{ap}{ap + (1 - a)(n - 1)^{-1}(1 - p)} \quad \dots (30);$$

and if two witnesses say so, it is

$$\frac{app'}{app' + (1 - a)(n - 1)^{-2}(1 - p)(1 - p')} \quad \dots (31).$$

It is easily shown in formula (30) that if  $p > n^{-1}$  the probability  $\omega$  is increased by the testimony, beyond  $a$ , its antecedent value. Thus, suppose there are ten horses in a race, and that one of them, A, has a chance  $\frac{1}{10}$  of winning, and that just after the race I learn that a black horse has won, black being A's colour; now, if I know that  $\frac{1}{10}$  of racehorses in general are black, this gives me a new chance  $\frac{1}{10}$  (see art. 16) that A has won. Therefore from (30) the chance of the event is now  $\frac{1}{9} = \frac{1}{10}$ .

35. To illustrate the effect of *discordant* testimony. In art. 29 let A have asserted that the fact occurred, and let B deny it. It is easy to see that  $1 - p'$  is to be put for  $p'$ , so that the probability that it did occur is

$$\frac{p(1 - p')}{p(1 - p') + p'(1 - p)} \quad \dots (32);$$

if there had been an *a priori* probability  $a$  in favour of the fact this would have been

$$\frac{ap(1 - p')}{ap(1 - p') + p'(1 - a)(1 - p)} \quad \dots (33).$$

Thus if the credit of both witnesses were the same,  $p = p'$ , and we find from (33)  $\omega = a$ , so that the evidence has not altered the likelihood of the event.

36. Where the event may turn out in  $n$  equally probable ways as in art. 33, and the witness A asserts one to have occurred, say the ticket marked 1 to have been drawn, while the witness B asserts another, say the ticket marked 2; to find the chance that No. 1 was drawn.

By the same reasoning as in art. 33 we find for the chance

$$\frac{p(1 - p')}{p(1 - p') + (n - 1)^{-1}(1 - p)(n - 2 + p')} \quad \dots (34).$$

This result will also follow if we consider B's evidence as testimony *in favour* of No. 1 of the value  $(1 - p')(n - 1)^{-1}$ .

When the number of tickets  $n$  is very great, (34) gives

$$\frac{p - pp'}{1 - pp'}.$$

37. As remarked in art. 26, the methods we have given for determining the probability of testimony apply to cases where the evidence is derived from other sources. Thus, suppose it has been found that a certain symptom (A) indicates the presence of a certain disease in three cases out of four, there is a probability  $\frac{3}{4}$  that any patient exhibiting the symptom has the disease. This, however, must be considered in conjunction with the *a priori* probability of the presence of the disease, if we wish to know the value of the evidence deduced from the symptom being observed. For instance, if we knew that  $\frac{3}{4}$  of the whole population had the disease, the evidence would have no value, and the credibility of the symptom *per se* would be  $\frac{1}{4}$ , telling us nothing either way. For if  $a$  be the *a priori* probability,  $\omega$  that after the evidence,  $p$  the credibility of the evidence, we have found

$$\frac{ap}{ap + (1 - a)(1 - p)};$$

so that, if  $\omega = a$ ,  $p = \frac{1}{2}$ .

If  $\omega$  and  $a$  are given, the credibility  $p$  of the evidence is deduced from this equation, viz.,

$$p = \frac{(1 - a)\omega}{a + \omega - 2a\omega}.$$

38. Suppose now the probability of the disease when the symptom A occurs is  $\omega$  (that is, it is observed that the disease exists in  $\omega N$  cases out of a large number  $N$  where the symptom is found), and likewise the same probability when another *independent* symptom B occurs is  $\omega'$ . What is the probability of the disease where both symptoms occur?

Let  $a$  be the *a priori* probability of the disease in all the cases; then the value of the evidence of B is, as explained above,

$$p' = \frac{(1 - a)\omega'}{a + \omega' - 2a\omega'};$$

and this has to be combined with  $\omega$ , which is the probability of the disease after A is observed. We find the probability ( $\Pi$ ) required to be

$$\Pi = \frac{\omega p'}{\omega p' + (1 - \omega)(1 - p)};$$

whence 
$$\pi = \frac{(1-\alpha)\pi'}{(1-\alpha)\pi' + \alpha(1-\pi')(1-\pi')} \dots (35)^1$$

Thus, if the *a priori* probability of the disease in all the patients was  $\frac{1}{2}$ , and 3 out of 4 have the disease where A is observed, and also 3 out of 4 where B is observed, the chance is  $\frac{3}{4}$  that the disease exists when both symptoms are present.

This question illustrates the exceeding delicacy and care required in reasoning on probabilities. If we had combined the two given probabilities in the usual way without considering the *a priori* value (as would be correct if this were quite unknown, or  $=\frac{1}{2}$ ) we should have had

$$\pi = \frac{\pi'}{\pi' + (1-\pi')(1-\pi')}.$$

The fallacy of so doing will appear if we consider a large population, and a very uncommon disease, and that the latter is observed to exist in  $\frac{1}{2}$  the cases where the symptom A occurs, and also in  $\frac{1}{2}$  for the symptom B; this formula would give  $\frac{1}{2}$  for the chance when both are present. This is clearly absurd; for, both the disease and the symptoms being by hypothesis extremely rare, and the symptoms being independent, that is, having no connection with each other, it is next to impossible that any one individual of the  $\frac{1}{2}N(A)$ —calling  $N(A)$  the number who have the symptom A—who have not the disease should also be comprised in the  $\frac{1}{2}N(B)$  who have not the disease, because this  $\frac{1}{2}N(A)$ ,  $\frac{1}{2}N(B)$  are very small numbers (relatively) taken indiscriminately from the whole population who are free from the disease. It is different for the  $\frac{1}{2}N(A)$ ,  $\frac{1}{2}N(B)$  cases who have the disease; these cases all come out of the very small number  $N(D)$  who have the disease; therefore several individuals will be probably common to both; hence, if both symptoms coexist, it is highly probable that the case is one of the disease.

We find from (35) the true probability to be in the present case

$$\pi = 1 - \alpha,$$

so that, if only 1 in 1000 have the disease, the chance is 999 to 1, instead of an even one.

39. If a coin thrown  $m$  times has turned up head every time, the chance derived from this experience alone that the real facility for head exceeds  $\frac{1}{2}$  is, by formula (11),

$$\pi = \frac{\int_0^1 x^m dx}{\int_0^1 x^{m-1} dx} = 1 - \frac{1}{m+1}.$$

But there is here a very strong *a priori* presumption that the facility is  $\frac{1}{2}$ ; suppose then that there is a very small *a priori* probability ( $p$ ) that either in the coin itself or the way it is thrown there is something more favourable to head than to tail: after the new evidence the probability of this will be

$$\frac{p\pi}{p\pi + (1-p)(1-\pi)} = \frac{(2m+1-1)p}{(2m+1-2)p+1}.$$

Thus if there is an *a priori* probability  $\pi' = \pi$ , and if the coin has turned up head 5 times and never tail, the probability that the facility for head exceeds that for tail becomes

$$\frac{63}{62+1000} = \frac{60}{1000} \text{ nearly.}$$

40. From art. 19 we see that if a large number of trials  $m+n$  be made as to any event,  $m$  being favourable, it may be considered certain that the real facility differs from  $m/(m+n)$  by a very small fraction at most. If then our *a priori* idea as to the facility gives it outside the limits derived from formula (21), the evidence from experience will overrule our *a priori* presumption. Thus, if a shilling thrown up 1000 times gives head 560 times and tail 440, the evidence thus afforded that the throws were not fair is so much stronger than any antecedent conviction we could have to the contrary that we may conclude with certainty that, from some cause or other, head is more likely than tail.

41. Closely allied to the subject of our present section are the applications of the theory of probabilities to the verdicts of juries, the decisions of courts, and the results of elections. Our limits,

<sup>1</sup> Or thus: let  $N$  = whole population and  $n, n'$  the numbers who show the symptoms A and B respectively, all these numbers being large. Now  $aN$  = whole number who have the disease;  $\pi n, \pi' n'$  the numbers out of  $n, n'$  who have it. Now  $\pi n, \pi' n'$  are both comprised in  $aN$ ; and, out of  $\pi n'$ , the number also included in  $\pi n$  is the same fraction of  $\pi n$  that  $\pi' n'$  is of  $aN$ ; that is, the number who have both symptoms and the disease is

$$\frac{\pi n \pi' n'}{aN};$$

and those who have both symptoms and have not the disease is

$$(1-\pi)n \frac{(1-\pi')n'}{(1-\pi)N};$$

so that, if both symptoms are present, the odds that it is a case of the disease are as

$$\frac{\pi \pi'}{a} : \frac{(1-\pi)(1-\pi')}{1-a}.$$

however, will hardly allow of even a sketch of the methods given by Condorcet, Laplace, and Poisson, as it is not possible to render them intelligible within a short compass. We must therefore refer the reader to Todhunter's *History*, as well as the original works of these writers, especially to Poisson's *Recherches sur la Probabilité des Jugements*.

42. We will consider here one remarkable question given by Laplace, because the mathematical difficulty may be solved in a simpler way than by deducing it as a case of a general problem given in his chap. ii., or than Todhunter's method (see his p. 545), which depends on Lejeune Dirichlet's theorem in multiple integrals.

An event (suppose the death of a certain person) must have proceeded from one of  $n$  causes A, B, C, &c., and a tribunal has to pronounce on which is the most probable.

Let each member of the tribunal arrange the causes in the order of their probability according to his judgment, after weighing the evidence. To compare the presumption thus afforded by any one judge in favour of a specified cause with that afforded by the other judges, we must assign a value to the probability of the cause derived solely from its being, say, the  $r$ th on his list. As he is supposed to be unable to pronounce any closer to the truth than to say (suppose) D is more likely than C, C more likely than B, &c., the probability of any cause will be the average value of all those which that probability can have, given simply that it always occupies the same place on the list of the probabilities arranged in order of magnitude. As the sum of the  $n$  probabilities is always 1, the question reduces to this—

Any whole (such as the number 1) is divided at random into  $n$  parts, and the parts are arranged in the order of their magnitude—least, second, third, . . . greatest; this is repeated for the same whole a great number of times; required the mean value of the least, of the second, &c., parts, up to that of the greatest.

Let the whole in question be represented by a line  $AB=a$ , and let it be divided at random into  $n$  parts by taking  $n-1$  points indiscriminately on it. Let the required mean values be

$$\lambda_1 a, \lambda_2 a, \lambda_3 a, \dots, \lambda_n a,$$

where  $\lambda_1, \lambda_2, \lambda_3, \dots$  must be constant fractions. As a great number of positions is taken in  $AB$  for each of the  $n$  points, we may take  $a$  as representing that number; and the whole number  $N$  of cases will be

$$N = a^{n-1}.$$

The sum of the *least* parts, in every case, will be

$$S_1 = N \lambda_1 a = \lambda_1 a^n.$$

Let a small increment,  $Bb=\delta a$ , be added on to the line  $AB$  at the end B; the increase in this sum is  $\delta S_1 = n \lambda_1 a^{n-1} \delta a$ .

But, in dividing the new line  $Ab$ , either the  $n-1$  points all fall on  $AB$  as before, or  $n-2$  fall on  $AB$  and 1 on  $Bb$  (the cases where 2 or more fall on  $Bb$  are so few we may neglect them). If all fall on  $AB$ , the least part is always the same as before except when it is the last, at the end B of the line, and then it is greater than before by  $\delta a$ ; as it falls last in  $n-1$  of the whole number of trials, the increase in  $S_1$  is  $n-1 a^{n-1} \delta a$ . But if one point of division falls on  $Bb$ , the number of new cases introduced is  $(n-1) a^{n-2} \delta a$ ; but, the least part being now an infinitesimal, the sum  $S_1$  is not affected; we have therefore

$$\delta S_1 = n \lambda_1 a^{n-1} \delta a = n-1 a^{n-1} \delta a;$$

$$\therefore \lambda_1 = n^{-1}.$$

To find  $\lambda_2$ , reasoning exactly in the same way, we find that where one point falls on  $Bb$  and  $n-2$  on  $AB$ , as the least part is infinitesimal, the *second least* part is the *least* of the  $n-1$  parts made by the  $n-2$  points; consequently, if we put  $\lambda'_1$  for the value of  $\lambda_1$  when there are  $n-1$  parts only, instead of  $n$ ,

$$\delta S_2 = n \lambda_2 a^{n-1} \delta a = n-1 a^{n-1} \delta a + (n-1) a^{n-2} \lambda'_1 a \delta a,$$

$$\therefore n \lambda_2 = n-1 + (n-1) \lambda'_1; \text{ but } \lambda'_1 = (n-1)^{-1};$$

$$\therefore n \lambda_2 = n-1 + (n-1)^{-1}.$$

In the same way we can show generally that

$$n \lambda_r = n-1 + (n-1) \lambda'_{r-1};$$

and thus the required mean value of the  $r$ th part is

$$\lambda_r a = a^{n-1} \{ n^{-1} + (n-1)^{-1} + (n-2)^{-1} + \dots + (n-r+1)^{-1} \}. \dots (36).$$

Thus each judge implicitly assigns the probabilities

$$\frac{1}{n^2}, \frac{1}{n} \left( \frac{1}{n} + \frac{1}{n-1} \right), \frac{1}{n} \left( \frac{1}{n} + \frac{1}{n-1} + \frac{1}{n-2} \right), \dots$$

to the causes as they stand on his list, beginning from the lowest. Laplace now says we should add the numbers thus found on the different lists for the cause A, also for B, &c.; and that cause which has the greatest sum is the most probable. This doubtless seemed self-evident to him, but ordinary minds will hardly be convinced

of its correctness without proof. Let the lists of two of the judges be, beginning from the lowest,

B, H, R, K, A . . . .

C, K, D, H, B . . . .

Probabilities  $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5 \dots$

As the opinions of all the judges are supposed of equal weight, the cause H here is as likely as the cause K; but the probability that H or K was the cause is<sup>1</sup>

$$\lambda_2 + \lambda_4.$$

Hence prob. (H) + prob. (K) = 2 prob. (H) =  $\lambda_2 + \lambda_4$ ;

$$\therefore \text{prob. (H)} = \frac{1}{2}(\lambda_2 + \lambda_4);$$

that is, the probability of any cause is the mean of its probabilities on the two lists, the circumstance being clearly immaterial whether the same cause K is found opposite to it or not. The same follows for 3 or more lists.

43. Laplace applies the same method to elections. Suppose there are  $n$  candidates for an office; each elector is to arrange them in what he believes to be the order of merit; and we have first to find the numerical value of the merit he thus implicitly attributes to each candidate. Fixing on some limit  $\alpha$  as the maximum of merit,  $n$  arbitrary values less than  $\alpha$  are taken and then arranged in order of magnitude—least, second, third, . . . . greatest; to find the mean value of each.

Take a line  $AB = \alpha$ , and set off  $n$  arbitrary lengths  $AX, AY, AZ \dots$  beginning at A; that is,  $n$  points are taken at random in AB. Now the mean values of  $AX, XY, YZ, \dots$  are all equal; for if a new point P be taken at random, it is equally likely to be 1st, 2d, 3d, &c., in order beginning from A, because out of  $n+1$  points the chance of an assigned one being 1st is  $(n+1)^{-1}$ ; of its being 2d  $(n+1)^{-1}$ ; and so on. But the chance of P being 1st is equal to the mean value of  $AX$  divided by  $AB$ ; of its being 2d  $XY$  divided by  $AB$ ; and so on. Hence the mean value of  $AX$  is  $AB(n+1)^{-1}$ ; that of  $AY$  is  $2AB(n+1)^{-1}$ ; and so on. Thus the mean merit assigned to the several candidates is

$$0(n+1)^{-1}, 2\alpha(n+1)^{-1}, 3\alpha(n+1)^{-1} \dots n\alpha(n+1)^{-1}.$$

Thus the relative merits may be estimated by writing under the names of the candidates the numbers 1, 2, 3, . . . .  $n$ . The same being done by each elector, the probability will be in favour of the candidate who has the greatest sum.

Practically it is to be feared that this plan would not succeed, though certainly the most rational and logical one if the conditions are fulfilled—because, as Laplace observes, not only are electors swayed by many considerations independent of the merit of the candidates, but they would often place low down in their list any candidate whom they judged a formidable competitor to the one they preferred, thus giving an unfair advantage to candidates of mediocre merit.

There are, however, many cases where such objections would not apply, and therefore where Laplace's method would be certainly the most rational. Thus, suppose a jury or committee or board of examiners have to decide on the relative merit of a number of prize essays, designs for a building, &c.; each member should place them in what he judges to be the order of merit, beginning with the worst, and write over them the numbers 1, 2, 3, 4, &c.; then the relative merit of each essay, &c., would be represented by the sum of the numbers against it in each list. No doubt there would be cases where a juror would observe a great difference in merit between one essay and the one below it, which difference would not be adequately rendered by an excess of 1 in the number. But even then, as such superiority could not fail to be recognized by the other members of the tribunal, it is not likely that any injustice would result.

44. An argument advanced in support of a proposition differs from the case of testimony in that, if the argument is bad, the previous probability of the conclusion is unaffected. Let  $p$  be the *a priori* probability of the proposition,  $q$  the chance that the argument is correct; then, in a large number  $N$  of cases, in  $qN$  the argument is good, and therefore the proposition is true; and out of the remaining  $(1-q)N$ , where the argument is bad, there are  $p(1-q)N$  cases where the proposition is nevertheless true. Hence the probability of the conclusion is

$$p + q - pq.$$

Hence any argument, however weak, adds something to the force of preceding arguments.

<sup>1</sup> This is the same as if there was only one judge. If both presented all the causes in the same order the probabilities are the same as if there were one; if now one judge transposes two causes, he does not alter the chance that one or other of them is true; and again this chance solely depends on the positions of the two causes in the lists, and is the same whatever the arrangements as to the remaining causes.

## V. ON MEAN VALUES AND THE THEORY OF ERRORS.

45. The idea of a mean or average among many differing magnitudes of the same kind is one continually employed, and of great value. It gives us in one result, easily pictured to the mind and easily remembered, a general idea of a number of quantities which perhaps we have never seen or observed, and we can thus convey the same idea to others, without giving a long list of the quantities themselves. We could scarcely form any clear conception as to the duration of human life, unless by taking the average,—that is, finding the length of life each individual would have if the whole sum of the years attained by each were equally divided among the entire population. How, again, could we so easily form an idea of the climate of Rome or Nice as by learning the mean of the temperatures of each day for a year, or a series of years? Here, again, it will be an important addition to the information to find also the mean summer temperature and the mean in winter, as we thus learn what extremes of heat and cold are to be expected. We may even go further and inquire the diurnal variation in the temperature in summer or in winter; and for this we should know the average of a number of particular cases.

It may be said that the whole value of statistics depends on the doctrine of averages. The price of wheat and of other commodities, the increase or decrease of a particular crime, the age of marriages both for men and women, the amount of rain at a given locality, the advance of education, the distribution of wealth, the spread of disease, and numberless other subjects for inquiry—are instances where we often see hasty and misleading conclusions drawn from one or two particular cases which happen to make an impression, but where the philosophical method bids us to observe the results in a large number, and then to present them as summed up and represented by the average or mean.

46. There is another application of averages of a different nature from the foregoing. Different estimates of the same thing are given by several independent authorities: thus the precise moment of an earthquake is differently stated by correspondents in the papers; different heights are given for a mountain by travellers; or suppose I have myself measured the height of a building a number of times, never obtaining exactly the same result. In all such cases (if we have no reason to attach greater weight to one result than to another) our common sense tells us that the average of all the estimates is more likely to be the truth than any other value. In these cases, as M. Quetelet remarks, there is this important distinction from the preceding, that the mean value represents a thing actually existing; whereas in the others it merely serves to give a kind of general idea of a number of individuals essentially different, though of the same kind. Thus if I take the mean of the heights of 200 houses in a long street, it does not stand for any real entity, but is a more ideal height, representing as nearly as possible those of the individual houses, whereas, in taking 200 measurements of the same house, their mean is intended to give, and will very nearly give, the actual height of that house.

47. So far it is obvious how to proceed in such cases; but it becomes a most important question in the theory of probabilities, to determine how far we can rely on the mean value of the different observations giving us the true magnitude we seek,—or rather, as we never can expect it to give exactly that value, to ascertain with what probability we may expect the error not to exceed any assigned limit. Such is the inquiry on which we are about to enter.

This investigation is of the more importance, because we find what is really the same problem present itself again under circumstances different from what we have been considering. In the measurement of any whole by means of repeated partial measurements—as, for instance, in measuring a distance by means of a chain—the error in the result is the sum of all the partial errors (with their proper signs) incurred at each successive application of the chain. If we would know, then, the amount of confidence we may have in the accuracy of the result, we must determine, as well as we can, the probability of the error—that is, the sum of all the partial errors—not exceeding assigned limits; and to this end, we have in the first place to try to determine the law of facility, or frequency, of different values of this sum. The problem only differs from the preceding in that here we seek for the facility of the sum of the errors; in the former, of the  $n$ th part of that sum.

In both these cases, we may reasonably and naturally suppose that the error incurred in each observation, or each measurement, follows the same law as to the frequency of its different possible values and as to its limits, as each is made by the same observer, under the same circumstances, though what that law is may be unknown to us. But there is another class of cases where the same problem presents itself. An astronomical observation is made (say) of the zenith distance of a star at a particular instant; the error in this determination is a complex one, caused by an error in the time, an error in the refraction, errors of the instru-

ment, personal error of the observer, and others. The error of the observation is in fact the sum of the partial errors arising from these different sources; now these evidently cannot be taken each to follow the same law, so that we have here a more general problem of the same species, viz., to combine a number of partial errors, each having its own law of facility and limits.

There is every reason to suppose that the error incurred in any single observation or measurement of any kind is generally due to the operation of a large number of independent sources of error; if we adopt this hypothesis, we have the same problem to solve in order to arrive at the law of facility of any single error.

48. We will consider the question as put by Poisson (*Recherches*, p. 254; see Todhunter, *History*, p. 561), and will adopt a method which greatly shortens the way to the result.

Let  $x$  be the error arising from the combination or superposition of a large number of errors  $\epsilon_1, \epsilon_2, \epsilon_3, \dots$  each of which by itself is supposed very small, then

$$x = \epsilon_1 + \epsilon_2 + \epsilon_3 + \dots \quad (37).$$

Each partial error is capable of a number, large or small, of values, all small in themselves; and this number may be quite different for each error  $\epsilon_1, \epsilon_2, \epsilon_3, \dots$ . There may be more positive than negative, or less, for each.<sup>1</sup> If  $n_1, n_2, n_3, \dots$  be the numbers of values of the several errors, the number of different values of the compound error  $x$  will be

$$n_1 n_2 n_3 \dots$$

We will suppose it, however, to take an indefinite number of values  $N$ , some multiple of the above, so that the  $n_1, n_2, n_3, \dots$  different values are repeated, but all equally often, so as to leave the relative facility of the different values unaltered. We will suppose the same number  $N$  of values in every case, whether more or fewer of the partial errors  $\epsilon_1, \epsilon_2, \epsilon_3, \dots$  are included or not.

Let the frequency of an error of magnitude  $x$  be called  $y$ , and let the equation expressing the frequency be

$$y = f(x) \quad (38);$$

i.e.,  $y dx$  = number of values of  $x$  between  $x$  and  $x + dx$ .

The whole number of values is

$$N = \int_{\mu}^{\mu'} f(x) dx,$$

where  $\mu, \mu'$  are the sums of the higher and lower limits of all the partial errors.

If now a new partial error  $\epsilon$  be included with the others, let it have  $n$  particular values  $\epsilon, \epsilon', \epsilon'', \dots$ ; if it had but the one value  $\epsilon$ , then to every value  $x$  of the old compound error would correspond one  $x'$  of the new, such that  $x + \epsilon = x'$ ; and the number of values of the new from  $x'$  to  $x' + dx'$  is the same as of the old from  $x$  to  $x + dx$ —that is,  $f(x) dx$ , or  $f(x' - \epsilon) dx'$ . Now the next value  $\epsilon'$  gives, besides these, the number  $f(x' - \epsilon') dx'$ , and so on. Thus the whole number of values of the new compound error between  $x'$  and  $x' + dx'$  is

$$\{f(x' - \epsilon) + f(x' - \epsilon') + f(x' - \epsilon'') + \dots\} dx'.$$

Hence the equation of frequency for the new error is (dropping the accent, and dividing by  $n$ —that is, reducing the total number of values from  $Nn$  to  $N$ , the same as before)

$$y = n^{-1} \{f(x - \epsilon) + f(x - \epsilon') + f(x - \epsilon'') + \dots\} \quad (39).$$

Hence

$$y = f(x) - \frac{\epsilon + \epsilon' + \epsilon'' + \dots}{n} f'(x) + \frac{\epsilon^2 + \epsilon'^2 + \epsilon''^2 + \dots}{2n} f''(x),$$

neglecting higher powers of  $\epsilon, \epsilon', \dots$ .

Hence if a new partial error  $\epsilon$ , whose mean value =  $a$ , and whose mean square is  $\lambda$ , be superposed on the compound error (38) resulting from the combination of a large number of partial errors, the equation of frequency for the resulting error is

$$y = f(x) - a f'(x) + \frac{1}{2} \lambda f''(x) = (1 - aD + \frac{1}{2} \lambda D^2) f(x) \quad (40).$$

It thus appears that each of the small errors only enters the result by its mean value  $a$ , and mean square  $\lambda$ .

If a second error were superposed, we should thus have

$$y = (1 - a_1 D + \frac{1}{2} \lambda_1 D^2) (1 - a_2 D + \frac{1}{2} \lambda_2 D^2) f(x);$$

$$\therefore y = \{1 - (a_1 + a_2) D + \frac{1}{2} (\lambda_1 + \lambda_2) + a_1 a_2 D^2\} f(x);$$

as  $\lambda$  is a lower infinitesimal than  $a$ , we retain no other terms.

$$\therefore y = \left\{1 - (a_1 + a_2) D + \frac{\lambda_1 + \lambda_2 - a_1^2 - a_2^2 + (a_1 + a_2)^2}{2} D^2\right\} f(x).$$

Thus any two errors enter the result in terms of  $a + a_2$  and  $\lambda + \lambda' - a^2 - a_2^2$ ; as this holds for any two, it is easy to see that all the partial errors in (37) enter the equation of frequency (38) only in terms of  $m$  and  $h - i$ ; putting

$$\left. \begin{aligned} m &= a_1 + a_2 + a_3 + \dots = \text{sum of mean errors,} \\ h &= \lambda_1 + \lambda_2 + \lambda_3 + \dots = \text{sum of mean squares of errors,} \\ i &= a_1^2 + a_2^2 + a_3^2 + \dots = \text{sum of squares of mean errors,} \end{aligned} \right\} \quad (41).$$

<sup>1</sup> An error may have all its values positive, or all negative. In estimating the instant when a star crosses the meridian we may err in excess or defect, but in estimating that when it emerges from behind the moon, we can only err in excess. We have heard this instance given by Clerk Maxwell.

Thus,

$$y = f(x) \equiv F(x, m, h - i).$$

Let  $m$  receive an increment  $\delta m$ ; this is equivalent to superposing a new error whose mean value is  $\delta m$ , and mean square infinitely smaller (e.g., let its values be all  $+$ , or indeed we may take it to have but the single value  $\delta m$ );

$$\therefore \delta y = \frac{dy}{dm} \delta m = - \frac{dy}{dx} \delta m, \text{ by (40);}$$

$$\therefore \frac{dy}{dm} = - \frac{dy}{dx}.$$

Hence  $y$  is a function of  $x - m$ ; so our equation must be of the form

$$y = F(x - m, h - i) \quad (42).$$

Let  $h$  receive an increment  $\delta h$ ; or conceive a new error whose mean value  $a = 0$ , and whose mean square =  $\delta h$ ; we have (40)

$$\frac{dy}{dh} \delta h = \frac{1}{2} \frac{d^2 y}{dx^2} \delta h.$$

$$\text{Hence} \quad \frac{d^2 y}{dx^2} = 2 \frac{dy}{dh} \quad (43).$$

Let us now suppose in (37) that all the values of every error are increased in the ratio  $r$ ; all the values of  $x$  are increased in the same ratio; consequently there are the same number of values of  $x$  from  $rx$  to  $r(x + dx)$  as there were before from  $x$  to  $x + dx$ . This gives

$$F(x - m, h - i) dx = F(rx - rm, r^2(h - i)) r dx,$$

for  $m$  is increased in the ratio  $r$ , and  $h$  and  $i$  in the ratio  $r^2$ .

Let us write for shortness

$$\xi = x - m, \quad \eta = h - i,$$

$$\text{so that} \quad y = F(\xi, \eta) \quad (44);$$

$$\text{we have} \quad r^{-1} F(\xi, \eta) \equiv F(r\xi, r^2\eta).$$

Let  $r = 1 + \omega$ , where  $\omega$  is infinitesimal;

$$(1 - \omega)y \equiv F(\xi + \omega\xi, \eta + 2\omega\eta);$$

$$\therefore y - \omega y = y + \omega \xi \frac{dy}{d\xi} + 2\omega \eta \frac{dy}{d\eta};$$

$$\therefore \xi \frac{dy}{d\xi} + 2\eta \frac{dy}{d\eta} + y = 0 \quad (45).$$

$$\text{This equation, and} \quad \frac{d^2 y}{d\xi^2} = 2 \frac{dy}{d\eta} \quad (46),$$

identical with (43), contain the solution of the problem.

Thus, (45) gives by integration

$$y = \eta^{\frac{1}{2}} \psi(\xi \eta^{-1}) \quad (47).$$

Again, combining (45) and (46),

$$\frac{d^2 y}{d\xi^2} + \xi \frac{dy}{d\xi} + y = 0,$$

$$\text{or} \quad \frac{d}{d\xi} \left( \eta \frac{dy}{d\xi} + \xi y \right) = 0;$$

$$\therefore \eta \frac{dy}{d\xi} + \xi y = \chi(\eta).$$

Substitute for  $y$  the value (47); and we find

$$2\xi \eta^{-\frac{1}{2}} \psi'(\xi \eta^{-1}) + \xi \eta^{-\frac{1}{2}} \psi(\xi \eta^{-1}) = \chi(\eta);$$

that is, a function of  $\xi \eta^{-1}$  identical with a function of  $\eta$ . This cannot be, unless both sides are constant. Hence  $\eta \frac{dy}{d\xi} + \xi y = c$ .

Now  $c = 0$ , for  $\frac{dy}{d\xi}$  vanishes with  $\xi$ , by (47); and,  $y$  being always finite, the left hand number vanishes with  $\xi$ ;

$$\therefore 2\psi'(\xi \eta^{-1}) + \psi(\xi \eta^{-1}) = 0.$$

$$\therefore \psi(\xi \eta^{-1}) = C e^{-\frac{1}{2} \xi^2 \eta^{-1}}.$$

Substituting in (47) and restoring the values of  $\xi, \eta$ , we find the form of the function (42) to be

$$y = C(h - i)^{-\frac{1}{2}} e^{-\frac{(x - m)^2}{2(h - i)}} \quad (48).$$

$C$  is a constant depending on the number  $N$ .

The probability of the error  $x$  falling between  $x$  and  $x + dx$  is found by dividing  $y dx$  by the whole area of the curve (48); i.e.,

$$p = \{2\pi(h - i)\}^{-\frac{1}{2}} e^{-\frac{(x - m)^2}{2(h - i)}} dx \quad (49).$$

49. If, instead of eq. (37), we had put

$$x = \gamma_1 \epsilon_1 + \gamma_2 \epsilon_2 + \gamma_3 \epsilon_3 + \dots \quad (50),$$

where  $\gamma_1, \gamma_2, \gamma_3, \dots$  are any numerical factors, the formula (49) gives the probability for  $x$ , provided  $h, i, m$  are taken to be

$$\left. \begin{aligned} m &= \gamma_1 a_1 + \gamma_2 a_2 + \gamma_3 a_3 + \dots \\ h &= \gamma_1^2 \lambda_1 + \gamma_2^2 \lambda_2 + \gamma_3^2 \lambda_3 + \dots \\ i &= \gamma_1^2 a_1^2 + \gamma_2^2 a_2^2 + \gamma_3^2 a_3^2 + \dots \end{aligned} \right\} \quad (51),$$

instead of the values in (41).

50. If we take the integral of eq. (49), between any two limits  $\mu, \nu$ , it gives us the probability that the sum  $x$  of the errors lies

between  $\mu$  and  $\nu$ —that is, that the mean of all the errors lies between  $\mu r^{-1}$  and  $\nu r^{-1}$ , if  $r$  is the number of the partial errors in (37).

The most likely value of  $x$  (that is, for which the frequency is greatest) is of course  $x=m$ , and the chance that  $x$  does not differ from  $m$  by more than  $\pm\delta$  is

$$w = \frac{1}{\sqrt{2\pi(h-i)}} \int_{m-\delta}^{m+\delta} e^{-\frac{(x-m)^2}{2(h-i)}} dx.$$

In this put  $(x-m)\{2(h-i)\}^{-1/2} = t$ ;  $\therefore dx = dt\sqrt{2(h-i)}$ .

The limits  $m \pm \delta$  for  $x$  become  $\pm\delta\{2(h-i)\}^{-1/2}$  for  $t$ ; hence, putting

$$\tau = \delta\{2(h-i)\}^{-1/2},$$

and remembering that  $\int_{-\tau}^{\tau} e^{-t^2} dt = 2 \int_0^{\tau} e^{-t^2} dt$ ,

we find 
$$w = \frac{2}{\sqrt{\pi}} \int_0^{\tau} e^{-t^2} dt \dots (52)$$

is the probability that the sum  $x$  of the errors in (37) lies between the limits  $m \pm \tau\sqrt{2(h-i)}$ ;  $w$  is also the probability that the mean of all the errors,  $x/r^{-1}$ , lies between the limits

$$mr^{-1} \pm \tau r^{-1} \sqrt{2(h-i)}.$$

51. The important result (48), which is the key to the whole theory of errors, contains several particular cases which Laplace gives in his fourth chapter. We may first make one or two remarks on it.

(1)  $h-i$  is always positive; for in (41)

$$\lambda_1 > a_1^2, \lambda_2 > a_2^2, \&c.,$$

because the mean of the squares of  $n$  numbers is always greater than the square of the mean.<sup>1</sup>

(2) To find the mean value  $M(x)$  of the sum  $x$ , and the mean value of its square  $M(x^2)$ , we have

$$M(x) = \frac{\int x y dx}{\int y dx}; \quad M(x^2) = \frac{\int x^2 y dx}{\int y dx},$$

the limits being  $\pm\infty$ . Hence

$$M(x) = m;$$

$$M(x^2) = m^2 + h - i.$$

The first is obvious from the fact that to every value  $m+x$  for  $x$  there corresponds another  $m-x$ . Both results also easily follow from common algebra: the case is that of a sum,  $x$ ,

$$x = e_1 + e_2 + e_3 + \&c.,$$

where each quantity  $e_1, e_2, e_3, \dots$  goes through an independent series of values; and it is easily proved that

$$M(x) = M(e_1) + M(e_2) + M(e_3) + \dots = \sum M(e_i);$$

$$M(x^2) = M(e_1^2) + M(e_2^2) + M(e_3^2) + \dots + 2\sum\{M(e_i)M(e_j)\} \\ = \sum M(e_i^2) + 2\sum\{M(e_i)M(e_j)\} + \sum M(e_i^2).$$

52. One particular case of the general problem in art. 48 is when the errors  $e_1, e_2, e_3, \dots$  in (37) all follow exactly the same law; as, for instance, if  $e_1, e_2, e_3, \dots$  are the errors committed in observing the same magnitude, under exactly the same circumstances, a great number of times; and we are asked to find the chance that the sum of the errors, or that their arithmetical mean, shall fall between given limits. Here the law of facility for each error is of course the same, though we may not know what it is.

We have then from (41)

$$m = ra_1, \quad h = r\lambda_1, \quad i = ra_1^2,$$

so that in eq. (52),

$$w = \frac{2}{\sqrt{\pi}} \int_0^{\tau} e^{-t^2} dt$$

is the probability that the mean of all the errors shall lie between

$$a_1 \pm \tau \sqrt{2r^{-1}(\lambda_1 - a_1^2)}$$

$a_1$  here is the mean of all the possible values of the error in this particular observation, which are of course infinite in number; and (53) shows us, what is evident beforehand, that the more the number  $r$  of observations is increased the narrower do the limits for the mean error become for a given probability  $w$ ; so that if, suppose, we take  $w=1$ , and  $r=\infty$ , we have very nearly  $w=1$ , and it becomes practically certain that the mean of the actual observations will differ from  $a_1$  by an infinitesimal deviation.

53. What we have found hitherto would be of very little practical use, because the constants involved suppose the amounts of the errors known, and therefore the true value known of the quantity which is observed or measured. It is, however, precisely this true value which we usually do not know and are trying to find. Let us now suppose a large number  $r$  of measurements, which we will call

$$a_1, a_2, \dots, a_r,$$

made of a magnitude whose true but unknown value is  $A$ .

<sup>1</sup> This may be very easily proved by reasoning precisely analogous to that employed in the note on article 24.

The (unknown) errors of the observations will be

$$e_1 = a_1 - A, \quad e_2 = a_2 - A, \quad e_3 = a_3 - A, \dots;$$

$$\therefore r^{-1}(e_1 + e_2 + \dots + e_r) = r^{-1}(a_1 + a_2 + \dots + a_r) - A;$$

or

$$M(e_1) = M(a_1) - A;$$

or the mean of the errors is the error committed in taking the mean of the observations as the value of  $A$ .

Hence (53)  $w$  is the probability that the error committed in taking the mean of the observations as the truth shall lie between

$$a_1 \pm \tau \sqrt{2r^{-1}(\lambda_1 - a_1^2)}.$$

Here  $a_1$  is the true mean of the errors of an infinite number of observations,  $\lambda_1$  the mean of their squares. As we have no means of determining  $a_1$  (except that it is nearly equal to the mean of the errors we are dealing with, which would give us no result), we have to limit the generality of the question by assuming that the law of error of the observation gives positive and negative errors with equal facility; if so  $a_1=0$ , and we have the probability  $w$  that the error lies between

$$\pm \tau \sqrt{2r^{-1}\lambda_1}.$$

Here  $\lambda_1$ , which is the mean of the squares of all possible values of the error of the observation, will be at least very nearly the mean square of the actual values of the errors, if  $r$  is large;

$$\therefore \lambda_1 = r^{-1}(e_1^2 + e_2^2 + \dots + e_r^2);$$

$$\therefore \lambda_1 = r^{-1}\{(a_1 - A)^2 + (a_2 - A)^2 + \dots + (a_r - A)^2\};$$

or

$$\lambda_1 = M(a_1^2) - 2AM(a_1) + A^2 \\ = M(a_1^2) - (Ma_1)^2 + (Ma_1 - A)^2.$$

Rejecting the last term, as the square of a very small quantity,

$$\lambda_1 = M(a_1^2) - (Ma_1)^2,$$

and we have the probability  $w$  (in (53)) that the error in taking the mean of the observations as the truth lies between

$$\pm \tau \sqrt{2r^{-1}\{M(a_1^2) - (Ma_1)^2\}} \dots (54),$$

a value depending on the mean square, and mean first power, of the observed values.

These limits may be put in a different form, rather easier for calculation. If  $f_1, f_2, f_3, \dots, f_r$  be the apparent errors, that is, not the real ones, but what they would be on the hypothesis that the mean is the true value, then, putting  $M$  for  $r^{-1}(a_1 + a_2 + \dots + a_r)$ ,

$$f_1 = a_1 - M, \quad f_2 = a_2 - M, \dots, \quad f_r = a_r - M;$$

$$\therefore M(f_1^2) = M(a_1^2) - 2M \cdot M + M^2 = M(a_1^2) - (Ma_1)^2;$$

so that  $\lambda = M(f_1^2)$ , and (54) may be written

$$\pm \tau \sqrt{2r^{-1} \cdot (f_1^2 + f_2^2 + \dots + f_r^2) r^{-1}} \dots (55).$$

54. In the last article we have made no assumption as to the law of frequency of the error in the observation we are considering, except that it gives positive and negative values with equal facility. If, however, we adopt the hypothesis (see art. 47) that every error in practice arises from the joint operation of a number of independent causes, the partial error due to each of which is of very small importance, then the process in art. 48 will apply, and we may conclude that the errors of every series of observations of the same magnitude made in the same circumstances follow the law of frequency in formula (48); and if we suppose, as is universally done, that positive and negative values are equally probable, the law will be

$$y = C e^{-1/2 c^2 x^2}$$

and the probability (49) will be

$$p = c^{-1} \pi^{-1/2} e^{-1/2 c^2 x^2} dx \dots (56),$$

where  $c$  is a constant, which is sometimes called the modulus of the system.

Every error in practice, then, is of the form (56), and is similar to every other. If  $c$  be small, the error has small amplitudes, and the series of observations are accurate.

If, as supposed in art. 53, a set of observations have been made, we can determine the modulus  $c$ , with an accuracy increasing with the number in the set. For (art. 51)

$$\frac{1}{2}c^2 = \text{true mean square of all possible values of the error.}$$

This we have called  $\lambda_1$  in last article, and have shown it nearly equal to  $M(a_1^2) - (Ma_1)^2$  or  $M(f_1^2)$ ; so that  $\frac{1}{2}c^2 = \text{mean square of obs.} - (\text{mean of obs.})^2 = \text{mean square of apparent errors.}$

55. Thus, if a set of observations have been made, and  $c$  thus determined from them, it is easy to see that

$$\left. \begin{aligned} \text{Mean error} &= \pm c \pi^{-1/2} = 0.5642c \\ \text{Mean square of error} &= \frac{1}{2}c^2 \\ \text{Probable error} &= \pm 0.4769c \end{aligned} \right\} \dots (57).$$

The mean error means that of all the positive or all the negative errors. The probable error is the value which half the errors exceed and half fall short of, so that it is an even chance that the error of any particular observation lies between the limits  $\pm 0.4769c$ . Its value is found from the table in art. 9, taking  $1=\frac{1}{2}$ .

56. We have often to consider the law of error of the sum of

several magnitudes, each of which has been determined by a set of observations. Suppose A and B two such magnitudes, and X their sum, to find the law of error in

$$X = A + B.$$

Let the functions of error for A and B be

$$c^{-1}e^{-\frac{1}{2}e^2}dx, \quad f^{-1}e^{-\frac{1}{2}f^2}dx.$$

In formula (49) let  $m=0$ ,  $i=0$ ,  $2h=c^2$ ; then the function for A is the law for the sum of a number of errors (37) the sum of whose mean squares is  $h=\frac{1}{2}c^2$ ; likewise that for B is the law for the sum of a number the sum of whose mean squares is  $\frac{1}{2}f^2$ ; the same formula (49) shows us that the law for the sum of these two series of errors—that is, for the sum of the errors of A and B—is

$$\left\{ \pi(c^2 + f^2) \right\}^{-\frac{1}{2}} e^{-\frac{1}{2}(c^2 + f^2)x^2} dx;$$

that is, the modulus for X or A + B is

$$\sqrt{c^2 + f^2}$$

Hence

$$\text{Probable error of } X = .4769 \sqrt{c^2 + f^2}$$

$$\therefore (\text{p.e. of } X)^2 = (\text{p.e. of } A)^2 + (\text{p.e. of } B)^2 \dots (58).$$

So likewise for the mean error.

If X were the difference A - B, (58) still holds.

If X be the sum of m magnitudes A, B, C, . . . instead of two, its probable error is in like manner

$$(\text{p.e. } X)^2 = (\text{p.e. } A)^2 + (\text{p.e. } B)^2 + \dots, \text{ \&c.};$$

and if the function of error for A, B, C, . . . be the same for all

$$(\text{p.e. } X)^2 = m(\text{p.e. } A)^2.$$

Also the probable error in the mean

$$M(A) = m^{-1}(A + B + C + \dots)$$

is the mth part of the above;

$$\therefore \text{p.e. of } M(A) = m^{-1}(\text{p.e. of } A) \dots (59).$$

Airy gives the following example. The co-latitude of a place is found by observing m times the Z.D. of a star at its upper culmination and n times its Z.D. at its lower culmination; to find the probable error.

By (59)

$$\text{p.e. upper Z.D.} = m^{-1}(\text{p.e. of an upper obs.});$$

$$\text{p.e. lower Z.D.} = n^{-1}(\text{p.e. of a lower obs.});$$

Now

$$\text{co-latitude} = \frac{1}{2}(\text{U. Z.D.} + \text{L. Z.D.}).$$

Hence (58)

$$(\text{p.e. co-lat.})^2 = \frac{1}{4}m^{-1}(\text{p.e. up. obs.})^2 + \frac{1}{4}n^{-1}(\text{p.e. low. obs.})^2.$$

If the upper Z.D. observations are equally good with the lower,

$$\text{p.e. co-lat.} = \frac{1}{2}(\text{p.e. an obs.})\sqrt{m^{-1} + n^{-1}}.$$

57. The magnitude to be found is often not observed directly, but another magnitude of which it is some function. Let A = true but unknown value of a quantity depending on another whose true unknown value is a, by the given function

$$A = f(a);$$

let an observed value for a be r, the corresponding value for A being V, then

$$V = f(r).$$

Let e = error of r, then the error of V is

$$V - A = f(a + e) - f(a) = ef'(r) \dots (60),$$

as r is nearly equal to a.

Suppose now the same magnitude A also a given function  $f_1(a_1)$  of a second magnitude  $a_1$ , which is also observed and found to be  $r_1$ ; also for a third, and so on; hence, writing  $C = f'(r)$ ,  $C_1 = f'_1(r_1)$ , &c.

$$\left. \begin{aligned} V - A &= f'(r) \cdot e = Ce \\ V_1 - A &= f'_1(r_1) \cdot e_1 = C_1e_1 \\ V_2 - A &= f'_2(r_2) \cdot e_2 = C_2e_2 \end{aligned} \right\} \dots (61);$$

and we have to judge of the best value for the unknown quantity, whose true value is called A. The arithmetical mean of  $V, V_1, V_2, \dots$  seems the simplest, but it is not here the most probable, and we shall assume it to be a different mean, viz.,

$$X = \frac{mV + m_1V_1 + m_2V_2 + \dots}{m + m_1 + m_2 + \dots}.$$

(As  $V, V_1, V_2, \dots$  are very nearly equal, it would be easy to show that any other way of combining them would be equivalent to this.) The factors  $m, m_1, m_2, \dots$  remain to be determined. From (61) the error of X is

$$X - A = \frac{mCe + m_1C_1e_1 + m_2C_2e_2 + \dots}{m + m_1 + m_2 + \dots} \dots (62).$$

Let the moduli of the errors  $e, e_1, e_2, \dots$  be  $c, c_1, c_2, \dots$  (see art. 56); then (see art. 42) for modulus of the error  $X - A$  we have

$$(\text{mod.})^2 = \frac{m^2C^2c^2 + m_1^2C_1^2c_1^2 + m_2^2C_2^2c_2^2 + \dots}{(m + m_1 + m_2 + \dots)^2} \dots (63).$$

If the factors  $mm_1m_2, \dots$  are determined so as to make this

modulus the least possible, the importance of the error  $X - A$  is the least possible.

Differentiate with regard to m, and we find

$$mC^2c^2 = \frac{m^2C^2c^2 + m_1^2C_1^2c_1^2 + \dots}{m + m_1 + m_2 + \dots}.$$

Likewise for  $m_1$ , and so on. Hence

$$mC^2c^2 = m_1C_1^2c_1^2 = m_2C_2^2c_2^2 = \dots, \text{ \&c.};$$

so that the most accurate mean to take is

$$X = \frac{\frac{V}{C^2c^2} + \frac{V_1}{C_1^2c_1^2} + \frac{V_2}{C_2^2c_2^2} + \dots}{\frac{1}{C^2c^2} + \frac{1}{C_1^2c_1^2} + \frac{1}{C_2^2c_2^2} + \dots} \dots (64).$$

The modulus of error in this value is, from (63),

$$\frac{1}{(\text{mod.})^2} = \frac{1}{C^2c^2} + \frac{1}{C_1^2c_1^2} + \frac{1}{C_2^2c_2^2} + \dots \dots (65).$$

58. The errors  $e, e_1, e_2, \dots$  are unknown. We have as to the first

$$V - A = ef'(r) = (r - a)f'(r).$$

Let the values of the quantities observed corresponding to the value X for that sought be  $x, x_1, x_2, \dots$

so that

$$X = f(x) = f_1(x_1) = f_2(x_2) \dots$$

then

$$X - A = (x - a)f'(r);$$

and, subtracting,

$$V - X = (r - x)f'(r) = (r - x)C.$$

Here  $V - X$  is the apparent error in V,  $r - x$  the apparent error of the observation r, taking X, x as the true values.

Of course we have also

$$V_1 - X = (r_1 - x_1)C_1, \quad V_2 - X = (r_2 - x_2)C_2, \dots$$

If now we were to determine X so as to render the sum of squares of apparent errors of the observations, each divided by the square of its modulus, a minimum,—that is,

$$\frac{(r - x)^2}{C^2} + \frac{(r_1 - x_1)^2}{C_1^2} + \dots = \frac{(V - X)^2}{C^2c^2} + \frac{(V_1 - X)^2}{C_1^2c_1^2} + \frac{(V_2 - X)^2}{C_2^2c_2^2} + \dots, \text{ \&c.},$$

a minimum,—we shall find the same value (64) for X.

Of course if the modulus is the same for all the observations the sum of squares simply is to be made a minimum.

To take a very simple instance. An observed value of a quantity is P; an observed value of a quantity known to be the square root of the former is Q; what is the most probable value?

If X be taken for the quantity, the apparent error of P is  $P - X$ ; the apparent error of Q is found from

$$(Q - e)^2 = X;$$

$$\therefore e = (Q^2 - X)/2Q;$$

$$\therefore (P - X)^2 + (Q^2 - X)^2/4Q^2 = \text{minimum};$$

$$\therefore X = (4P^2 + 1/Q^2)/(4Q^2 + 1);$$

the weight of both observations being supposed the same.

Again, suppose a circle is divided by a diameter into two semicircles; the whole circumference is measured and found to be L; also the two semicircles are found to be M and N respectively. What is the most probable value of the circumference?

If X be taken as the circumference, the apparent error in L is  $L - X$ ; those of M and N are  $M - \frac{1}{2}X$ ,  $N - \frac{1}{2}X$ . Hence, if all the measurements are equally good,

$$(L - X)^2 + (M - \frac{1}{2}X)^2 + (N - \frac{1}{2}X)^2 = \text{minimum},$$

$$\therefore X = \frac{1}{2}(M + N + 2L)$$

is the most probable value.

The modulus of error of this result is (65) found to be

$$(\text{mod.})^2 = \frac{1}{2}(\text{mod. of measurements})^2$$

so that

$$\text{probable error} = (\text{prob. error of a measurement})/\sqrt{2}.$$

59. In the last article we have explained the method of least squares, as applied to determine one unknown element from more than one observation of the element itself or of others with which it is connected by known laws. If several observations of the element itself are made, it is obvious that the method of least squares gives the arithmetical mean of the observations as the best value, thus justifying what common sense seems to indicate. If the observations are not equally good, the best value will be

$$X = \frac{wV + w_1V_1 + w_2V_2 + \dots}{w + w_1 + w_2 + \dots}$$

calling  $w, w_1, w_2, \dots$  the weights of the different observations  $V, V_1, V_2, \dots$

$$\text{i.e., } w = c^{-2}, \quad w_1 = c_1^{-2}, \quad w_2 = c_2^{-2}, \text{ \&c.}$$

It would carry us beyond our assigned limits in this article to attempt to demonstrate and explain the method of least squares when several elements have to be determined from a number of observations exceeding the elements in number. We must therefore refer the reader to the works already named, and also to the following:—Gauss, *Theoria Combinationis Observationum*; Gauss, *Theoria Motus*; Airy, *Theory of Errors of Observation*; Leslie Ellis, in *Camb. Phil. Trans.*, vol. viii.

The rule in such cases is that the sum of squares of the apparent errors is to be made a minimum, as in the case of a single element. To take a very simple example:—

A substance is weighed, and the weight is found to be  $W$ . It is then divided into two portions, whose weights are found to be  $P$  and  $Q$ . What is the most probable weight of the body?

Taking  $A$  and  $B$  as the weights of the two portions, the apparent errors are  $P - A$ ,  $Q - B$ , and that of the whole is  $W - A - B$ ; hence

$$(P - A)^2 + (Q - B)^2 + (W - A - B)^2 = \text{minimum}$$

there being two independent variables  $A$ ,  $B$ .

$$\therefore P - A + W - A - B = 0;$$

$$Q - B + W - A - B = 0;$$

or

$$2A + B = P + W$$

$$2B + A = Q + W$$

$$\therefore A + B = \frac{1}{2}(P + Q + 2W);$$

$$A = \frac{1}{2}(2P + W - Q);$$

$$B = \frac{1}{2}(2Q + W - P);$$

which are the most probable weights of the whole and the two parts.

#### VI. ON LOCAL PROBABILITY.

60. It remains to give a brief account of the methods of determining the probabilities of the fulfilment of given conditions by variable geometrical magnitudes, as well as the mean values of such magnitudes. Recent researches on this subject have led to many very remarkable results; and we may observe that to English mathematicians the credit almost exclusively belongs. It is a new instance, added to not a few which have gone before, of a revival for which we have to thank the eminent men who during the 19th century have enabled the country of Newton to take a place less unworthy of her in the world of mathematical science.

At present the investigations on this subject have not gone beyond the theoretical stage; but they should not be undervalued on this account. The history of the theory of probabilities has sufficiently shown that what at first seems merely ingenious and a matter of curiosity may turn out to have valuable applications to practical questions. How little could Pascal, James Bernoulli, and De Moivre have anticipated the future of the science which they were engaged in creating!

61. The great naturalist Buffon was the first who proposed and solved a question of this description. It was the following:—

A floor is ruled with equidistant parallel lines; a rod, shorter than the distance between each pair, being thrown at random on the floor, to find the chance of its falling on one of the lines.

Let  $x$  be the distance of the centre of the rod from the nearest line,  $\theta$  the inclination of the rod to a perpendicular to the parallels,  $2a$  the common distance of the parallels,  $2c$  the length of rod; then, as all values of  $x$  and  $\theta$  between their extreme limits are equally probable, the whole number of cases will be represented by

$$\int_0^a \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} dx d\theta = \pi a.$$

Now if the rod crosses one of the lines we must have  $c > \frac{x}{\cos \theta}$ ; so that the favourable cases will be measured by

$$\int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} d\theta \int_0^{c \cos \theta} dx = 2c.$$

Thus the probability required is  $p = 2c/\pi a$ .

Laplace in solving this question suggests that by making a great number of trials, and counting the cases where the rod falls on a line, we could determine the value of  $\pi$  from this result. He further considers, for a given value of  $a$ , what length  $2c$  should be chosen for the rod so as to give the least chance of error in a given large number  $N$  of throws.

In art. 8 we have shown that the chance that the number of successes shall lie between  $pN \pm r$  is

$$\frac{1}{\sqrt{\pi}} \int_0^{\frac{r}{\sqrt{p(1-p)}}} e^{-x^2} dx,$$

where

$$a^2 = \frac{1}{2p(1-p)N}.$$

For a given probability  $p$ ,  $ra$  is given. We have then a given chance that the number of successes shall differ from its most probable value  $pN$  by an error  $r$  which is the least possible fraction of the latter when  $r/pN$ , or when  $1/\sqrt{p(1-p)}$ , or when  $\sqrt{p(1-p)}/p$  is the least possible; that is, when  $p^{-1} - 1 = \pi a/2c - 1$  is the least

<sup>1</sup> If  $S$  = number of successes, we have an assigned chance  $\omega$  that  $S$  lies between  $pN \pm r$ ; that is, the value of  $\pi$  lies between  $\frac{2c}{a} \frac{N}{S \pm r}$ , or  $\frac{2c}{a} \left( \frac{N}{S} \pm \frac{Nr}{S^2} \right)$ . Hence the error in  $\pi$  is least when  $2c/rS^2$  is least. Now  $\frac{2c}{a} \sqrt{p(1-p)}$ ,  $2c\omega/p$ , and  $S\omega c/p$  nearly; hence  $\sqrt{p(1-p)}/p$  is to be the least possible.

possible, or when  $c$  is the greatest possible. Now the greatest value of  $c$  is  $a$ ; the rod therefore should be equal to the distance between the lines.

Laplace's answer is incorrect, though originally given right, (see Todhunter, p. 591; also Czuber, p. 90).

62. Questions on local probability and mean values are of course reducible, by the employment of Cartesian or other coordinates, to multiple integrals. Thus any one relating to the position of two variable points, by introducing their coordinates, can be made to depend on quadruple integrals,—whether in finding the sum of the values of a given function of the coordinates, with a view to obtaining its mean value, or in finding the number of the favourable cases, when a probability is sought. The intricacy and difficulty to be encountered in dealing with such multiple integrals and their limits is so great that little success could be expected in attacking such questions directly by this method; and most of what has been done in the matter consists in turning the difficulty by various considerations, and arriving at the result by evading or simplifying the integrations. We have a certain analogy here in the variety of contrivances and artifices used in arriving at the values of definite integrals without performing the integrations. We will now select a few of such questions.

63. If a given space  $S$  is included within a given space  $A$ , the chance of a point  $P$ , taken at random on  $A$ , falling on  $S$ , is

$$p = S/A.$$

But if the space  $S$  be variable, and  $M(S)$  be its mean value

$$p = M(S)/A \dots \dots \dots (66).$$

For, if we suppose  $S$  to have  $n$  equally probable values  $S_1, S_2, S_3, \dots$ , the chance of any one  $S_1$  being taken, and of  $P$  falling on  $S_1$ , is

$$p_1 = n^{-1} S_1/A;$$

now the whole probability  $p = p_1 + p_2 + p_3 + \dots$ , which leads at once to the above expression.

The chance of two points falling on  $S$  is, in the same way,

$$p = M(S^2)/A^2 \dots \dots \dots (67);$$

and so on.

In such a case, if the probability be known, the mean value follows, and *vice versa*. Thus, we might find the mean value of the  $n$ th power of the distance  $XY$  between two points taken at random in a line of length  $l$ , by considering the chance that, if  $n$  more points are so taken, they shall all fall between  $X$  and  $Y$ . This chance is

$$M(XY)^n/l^n = 2(n+1)^{-1}(n+2)^{-1};$$

for the chance that  $X$  shall be one of the extreme points, out of the whole  $(n+2)$ , is  $2(n+2)^{-1}$ ; and, if it is, the chance that the other extreme point is  $Y$  is  $(n+1)^{-1}$ . Therefore

$$M(XY)^n = 2l^n(n+1)^{-1}(n+2)^{-1}.$$

64. A line  $l$  is divided into  $n$  segments by  $n-1$  points taken at random; to find the mean value of the product of the  $n$  segments.

Let  $a, b, c, \dots$  be the segments in one particular case. If  $n$  new points are taken at random in the line, the chance that one falls on each segment is

$$1.2.3 \dots n.ab.c \dots /l^n;$$

hence the chance that this occurs, however the line is divided, is  $[n!^{-1} M(ab.c \dots)]$ .

Now the whole number of different orders in which the whole  $2n-1$  points may occur is  $[2n-1]$ ; out of these the number in which one of the first series falls between every two of the second is easily found by the theory of permutations to be

$$[n][n-1].$$

Hence the required mean value of the product is

$$M(ab.c \dots) = \frac{[n-1]}{[2n-1]} l^n.$$

65. If  $M$  be the mean value of any quantity depending on the positions of two points (*e.g.*, their distance) which are taken, one in a space  $A$ , the other in a space  $B$  (external to  $A$ ); and if  $M'$  be the same mean when both points are taken indiscriminately in the whole space  $A+B$ ;  $M_a, M_b$  the same mean when both points are taken in  $A$  and both in  $B$  respectively; then

$$(A+B)^2 M' = 2ABM + A^2 M_a + B^2 M_b.$$

If the space  $A=B$ ,

$$4M' = 2M + M_a + M_b;$$

if, also,  $M_a = M_b$ ,

$$2M' = M + M_a.$$

66. The mean distance of a point  $P$  within a given area from a fixed straight line (which does not meet the area) is evidently the distances of the centre of gravity  $G$  of the area from the line. Thus, if  $A, B$  are two fixed points on a line outside the area, the mean value of the area of the triangle  $APB$  = the triangle  $AGB$ .

From this it will follow that, if  $X, Y, Z$  are three points taken at random in three given spaces on a plane (such that they cannot

all be cut by any one straight line), the mean value of the area of the triangle XYZ is the triangle GG'G'', determined by the three centres of gravity of the spaces. For example—

Two points X, Y are taken at random within a triangle. What is the mean area M of the triangle XYZ, formed by joining them with one of the angles of the triangle?

Bisect the triangle by the line CD; let  $M_1$  be the mean value when both points fall in the triangle ACD, and  $M_2$  the value when one falls in ACD and the other in BCD; then  $2M = M_1 + M_2$ . But  $M_1 = \frac{1}{2}M$ ; and  $M_2 = GG'C$ , where G, G' are the centres of gravity of ACD, BCD, this being a case of the above theorem; hence  $M_2 = \frac{1}{3}ABC$ , and

$$M = \frac{4}{7}ABC.$$

Hence the chance that a new point Z falls on the triangle XYZ is  $\frac{4}{7}$ ; and the chance that three points X, Y, Z taken at random form, with a vertex C, a re-entrant quadrilateral, is  $\frac{3}{7}$ .

67. If M be a mean value depending on the positions of n points falling on a space A; and if this space receive a small increment a, and M' be the same mean when the n points are taken on A + a, and  $M_1$  the same mean when one point falls on a and the remaining n-1 on A; then, the sum of all the cases being  $M'(A+a)^n$ , and this sum consisting of the cases (1) when all the points are on A, (2) when one is on a the others on A (as we may neglect all where two or more fall on a), we have

$$M'(A+a)^n = M A^n + n M_1 a A^{n-1};$$

$$\therefore (M' - M)A = n a (M_1 - M) \dots \dots (65),$$

as  $M'$  nearly = M.

As an example, suppose two points X, Y are taken in a line of length l, to find the mean value M of (XY)<sup>n</sup>, as in art. 63.

If l receives an increment dl, formula (63) gives

$$ldM = 2dl(M_1 - M).$$

Now  $M_1$  here—the mean nth power of the distance of a single point taken at random in l from one extremity of l; and this is  $l^{n+1}(n+1)^{-1}$  (as is shown by finding the chance of n other points falling on that distance); hence

$$ldM = 2dl \{ l^n (n+1)^{-1} - M \};$$

$$\therefore ldM + 2Mdl = 2l^n (n+1)^{-1} dl,$$

or

$$l^{-1} d. Ml^n = 2(n+1)^{-1} l^n dl;$$

$$\therefore Ml^n = 2(n+1)^{-1} \int l^{n+1} dl = 2l^{n+2} (n+1)^{-1} (n+2)^{-1} C;$$

$$\therefore M = 2l^n (n+1)^{-1} (n+2)^{-1},$$

as in art. 63, C being evidently 0.

63. If p is the probability of a certain condition being satisfied by the n points within A in art. 67, p' the same probability when they fall on the space A + a, and  $p_1$  the same when one point falls on a and the rest on A, then, since the numbers of favourable cases are respectively  $p'(A+a)^n$ ,  $pA^n$ ,  $np_1 a A^{n-1}$ , we find

$$(p' - p)A = n a (p_1 - p) \dots \dots (69).$$

Hence if  $p' = p$  then  $p_1 = p$ ; this result is often of great value. Thus if we have to find the chance of three points within a circle forming an acute-angled triangle, by adding an infinitesimal concentric ring to the circle, we have evidently  $p' = p$ ; hence the required chance is unaltered by assuming one of the three points taken on the circumference.

Again, in finding the chance that four points within a triangle shall form a convex quadrilateral, adding to the triangle a small band between the base and a line parallel to it, the chance is clearly unaltered. Therefore by (69) we may take one of the points at random in the base of the triangle without altering the probability.

69. Historically, it would seem that the first question given on local probability, since Buffon, was the remarkable four-point problem of Prof. Sylvester. It is, in general, to find the probability that four points taken at random within a given boundary shall form a re-entrant quadrilateral. It is easy to see that this problem is identical with the problem of finding the mean area of the triangle formed by three points taken at random; for, if M be this mean, and A the given area, the chance of a fourth point falling on the triangle is  $M/A$ ; and the chance of a re-entrant quadrilateral is four times this, or  $4M/A$ .

Let the four points be taken within a triangle. We may take one of them W (fig. 3) at random on the base (art. 68); the others X, Y, Z within the triangle. Now the four lines from the vertex B to the four points are as likely to occur in any specified order as any other. Hence it is an even chance that X, Y, Z fall on one of the triangles ABW, CBW, or that two fall on one of these triangles and the

Fig. 3.

remaining one on the other. Hence the probability of a re-entrant quadrilateral is

$$\frac{1}{2}p_1 + \frac{1}{2}p_2,$$

where  $p_1$  = prob. (WXYZ re-entrant), X, Y, Z in one triangle;

$p_2$  = do., X in one triangle, Y in the other, Z in either.

But  $p_1 = \frac{1}{2}$  (art. 65). Now to find  $p_2$ ; the chance of Z falling within the triangle WXY is the mean area of WXY divided by ABC. Now by the principle in art. 66, for any particular position of W,  $M(WXY) = WGG'$ , where G, G' are the centres of gravity of ABW, CBW. It is easy to see that  $WGG' = \frac{1}{3}ABC$ , putting  $ABC = 1$ . Now, if Z falls in CBW, the chance of WXYZ re-entrant is  $2M(WY)W$ , for Y is as likely to fall in WXZ as Z to fall in WXY; also if Z falls in ABW the chance of WXYZ re-entrant is  $2M(WX)W$ . Thus the whole chance is  $p_2 = 2M(WY)W + 2M(WX)W = \frac{2}{3}$ .

Hence the probability of a re-entrant quadrilateral is

$$\frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{2}{3} = \frac{5}{12}.$$

That of its being convex is  $\frac{7}{12}$ .

70. If three points X, Y, Z are taken at random in a triangle. the mean value of the triangle XYZ =  $\frac{1}{7}$  of the given triangle. For we have seen that the chance of four points forming a re-entrant figure is  $4M/A$ , where M is the required mean and A the given triangle; as this has been shown to be  $\frac{5}{12}$ ,

$$M = \frac{1}{12}A.$$

71. Let the three points be taken within a circle; and let M be the mean value of the triangle formed. Adding a concentric ring a we have (65) since  $M':M$  as the areas of the circles,  $M' = \frac{A+a}{A}M$ .

$$\therefore \frac{A+a}{A}M = 3a(M_1 - M); \therefore M = \frac{3}{2}M_1,$$

where  $M_1$  is the value of M when one of the points is on the circumference.

Take O fixed; we have to find the mean value of OXY (fig. 4). Taking  $(\rho, \theta)$  as coordinates of X, Y,

$$M_1 = (a^2)^{-2} \iint \rho^2 d\rho d\theta \iint \rho^2 d\rho d\theta' . (OXY).$$

$$\therefore M_1 = (a^2 a^4)^{-1} \iiint \frac{1}{2} \rho \rho' \sin(\theta - \theta') \rho \rho' d\rho d\rho' d\theta d\theta'$$

$$= (a^2 a^4)^{-1} \cdot \frac{1}{2} \iint \frac{1}{2} r^2 r'^2 \sin(\theta - \theta') d\theta d\theta',$$

putting  $r = OH$ ,  $r' = OK$ ; as  $r = 2a \sin \theta$ ,  $r' = 2a \sin \theta'$ ,

$$M_1 = \frac{1}{2a^2} \cdot \frac{(2a)^2}{9} \int_0^\pi \int_0^\pi \sin^2 \theta \sin^2 \theta' \sin(\theta - \theta') d\theta d\theta'.$$

Professor Sylvester has remarked that this double integral, by means of the theorem

$$\int_0^a \int_0^a f(x, y) dx dy = \int_0^a \int_0^a f(a-y, a-x) dx dy,$$

is easily shown to be identical with

$$2 \int_0^\pi \int_0^\pi \sin^4 \theta \sin^2 \theta' \cos \theta' d\theta d\theta' = \frac{1}{2} \int_0^\pi \sin^2 \theta d\theta = \frac{1}{2} \cdot \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6 \cdot 8}.$$

$$\therefore M_1 = \frac{35a^2}{26\pi}; \therefore M = \frac{35}{48\pi} a^2.$$

Hence the probability that four points within a circle shall form a re-entrant figure is

$$p = \frac{35}{12\pi^2}.$$

72. Professor Sylvester has remarked that it would be a novel question in the calculus of variations to determine the form of the convex contour which renders the probability a maximum or minimum that four points taken within it shall give a re-entrant quadrilateral. It will not be difficult to show, by means of the principles we have been examining, that the circle is the contour which gives the minimum.

For, if p be the probability of a re-entrant figure for four points within a circle of area A, p' the same probability when a small addition a, of any kind which still leaves the whole contour convex, is made to the circle, we have by (69)

$$(p' - p)A = 4a(p_1 - p),$$

where  $p_1$  = the probability when one point is taken in a—that is, in the limit, when one point is taken on the circumference of the circle. But  $p_1 = p$ , as is shown in art. 65; hence

$$p' - p = 0.$$

Hence any infinitesimal variation of the contour from the circumference of the circle gives  $\delta p$ , the variation of the probability, zero,—the same method being applicable when portions are taken away, instead of being added, provided the contour is left convex.

Fig. 4.

Hence, for the circle, the probability is a maximum or minimum. It will be a minimum, because in the formula (68) for the mean triangle formed by three points

$$(M' - M)A - 3a(M_1 - M).$$

$M_1$ , which is the mean triangle when one point is in  $a$ , is really greater than when it is on the circumference, though the same in the limit; hence

$$\begin{aligned} M_1 &> \frac{1}{2}M; \\ \therefore (M' - M)A &> aM; \\ \therefore M'/(A + a) &> M/A. \end{aligned}$$

Therefore, if we consider infinitesimals of the second order, the chance of a re-entrant figure is increased by the addition of the space  $a$  to the circle. It will be an exercise for the reader to verify this when the space is subtracted.

For an ellipse, being derived by projection from the circle, the probability is the same, and a minimum.

It is pretty certain that a triangle will be found to be the contour which gives the probability the greatest.

Mr Woolhouse has given (*Educ. Times*, Dec. 1867) the values of  $p$  for

	Triangle.	Parallelogram.	Reg. Hexagon.	Circle.
$p =$	$\frac{1}{2}$ or .3333	$\frac{1}{3}$ .3056	$\frac{2}{3}$ .2973	$\frac{1}{2}\pi^{-2}$ .2955

73. Many questions may be made to depend upon the four-point problem. Thus, if two points A, B are taken at random in a given convex area, to find the chance that two others C, D, also taken at random, shall lie on opposite sides of the line AB.

Let  $p$  be the chance that ABCD is re-entrant. If it is, the chance is easily seen to be  $\frac{1}{2}$  that any two of the four lie on opposite sides of the line joining the two others. If ABCD is convex, the same chance is  $\frac{1}{2}$ ; hence the required probability is

$$\omega = \frac{1}{2}p + \frac{1}{2}(1 - p) = \frac{1}{2} + \frac{1}{2}p.$$

Or we might proceed as follows, e.g., in the case of a triangle:—

The sides of the triangle ABC (fig. 5) produced divide the whole triangle into seven spaces. Of these, the mean value of those marked  $\alpha$  is the same, viz., the mean value of ABC, or  $\frac{1}{4}$  of the whole triangle, as we have shown,—the mean value of those marked  $\beta$  being  $\frac{3}{4}$  of the triangle.

This is easily seen: for instance, if the whole area = 1, the mean value of the space PBQ gives the chance that if the fourth point D be taken at random B shall fall within the triangle ADC; now the mean value of ABC gives the chance that D shall fall within ABC; but these two chances are equal. Hence we see that if A, B, C be taken at random, the mean value of that portion of the whole triangle which lies on the same side of AB as C does is  $\frac{1}{4}$  of the whole, and that of the opposite portion is  $\frac{3}{4}$ . Hence the chance of C and D falling on opposite sides of AB is  $\frac{1}{2}$ .

74. We can give but few of the innumerable questions depending on the position of points in a plane, or in space. Some may be solved without any aid from the integral calculus, by using a few very evident subsidiary principles. As an instance, we will state the following two propositions, and proceed to apply them to one or two questions:—

(1) In a triangle ABC, the frequency of any direction for the line CX is the same when X is a point taken at random on the base AB as when X is taken at random in the area of the triangle.

(2) If X (fig. 6) is a point taken at random in the triangle ABQ (BQ being infinitesimal), the frequency of the distance AX is the same as that of AZ, Y and Z being two points taken at random in AB, and Z denoting always that one of the two which is nearest to B. For the frequency in each case is proportional to the distance AX or AZ.

Let us apply these to the following question:—

A point O is taken at random in a triangle (fig. 7); if  $n$  more points are taken at random, to find the chance that they shall all lie on some one of the three triangles AOB, AOC, BOC.

If C be joined with all the points in question, every joining line is equally likely to be nearest to CB. Hence the chance that all the  $n$  points fall on the triangle ACD is

$$(n+1)^{-1}.$$

Fig. 5.

Fig. 6.

Fig. 7.

If this is so, we have to find the chance that all lie on AOC. Now if O range over the infinitesimal triangle DCd, we may, by principle (2) above, suppose it to be the nearest to D of two points taken at random in CD. If so, the chance that AO is nearer to AD than any of the lines from A to the  $n$  points is

$$2(n+2)^{-2};$$

for, by (1) above, we may suppose all the points taken at random in CD; now any one of the  $n+2$  is equally likely to be the last; and O is the last of the two additional points. Hence, if O is in the triangle CDd, the chance that the  $n$  points fall on AOC is

$$2(n+1)^{-1}(n+2)^{-1};$$

therefore this is the chance wherever O falls in ABC.

Therefore the required chance that the  $n$  points fall on some one of the triangles AOB, AOC, BOC is

$$P = 6(n+1)^{-1}(n+2)^{-1}.$$

Again, if O be taken at random in the triangle, and three more points X, Y, Z be also taken at random in it, to find the chance that they shall fall, one on each of the triangles AOB, AOC, BOC.

First, two of the points are to fall on one of the triangles ACD, BCD, and the remaining one on the other; say two on ACD, the chance of this is  $\frac{1}{2}$ , as CO must then be the third in order of the four distances from C. If this is so, the chance that the point X in BCD falls on BOC is  $\frac{1}{2}$ . For, as above, if O ranges over the triangle CDd, we may take it to be the lowest of two points taken at random on CD; and the chance that, if another point be also taken at random in CD, it shall be lower than O is  $\frac{1}{2}$ . Now if one of the points X is in BOC, the frequency of O in CDd will be the same as that of the lowest of three points taken on CD; and the chance that one of the remaining points shall fall in AOC and the other in AOD is the chance that O, the lowest of three particular points out of five, all taken at random in CD, shall be the fourth in order from C. It is easy to see that this chance is  $\frac{1}{7}$ . Hence the chance that one point falls on BOC, one on AOC, and the third on AOD is

$$\frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{7} = \frac{1}{14}.$$

And it will be the same for the case where the third falls on BOD. Hence the chance that one point falls on each of the three triangles above is double this, or  $\frac{1}{7}$ .

75. *Straight lines falling at random on a Plane.*—If an infinite number of straight lines be drawn at random in a plane, there will be as many parallel to any given direction as to any other, all directions being equally probable; also those having any given direction will be disposed with equal frequency all over the plane. Hence, if a line be determined by the coordinates  $p, \omega$ , the perpendicular on it from a fixed origin O, and the inclination of that perpendicular to a fixed axis, then, if  $p, \omega$  be made to vary by equal infinitesimal increments, the series of lines so given will represent the entire series of random straight lines. Thus the number of lines for which  $p$  falls between  $p$  and  $p+dp$ , and  $\omega$  between  $\omega$  and  $\omega+d\omega$ , will be measured by  $dpd\omega$ , and the integral

$$\iint dpd\omega,$$

between any limits, measures the number of lines within those limits.

It is easy to show from this that the number of random lines which meet any closed convex contour of length  $L$  is measured by  $L$ . For, taking O inside the contour, and integrating first for  $p$ , from 0 to  $p$ , the perpendicular on the tangent to the contour, we have  $\int p d\omega$ ; taking this through four right angles for  $\omega$ , we have by Legendre's theorem on rectification,  $N$  being the measure of the number of lines,

$$N = \int_0^{2\pi} p d\omega = L.$$

Thus, if a random line meet a given contour, of length  $L$ , the chance of its meeting another convex contour, of length  $l$ , internal to the former, is

$$p = l/L.$$

If the given contour be not convex, or not closed,  $N$  will evi-

1 This result also follows by considering that, if an infinite plane be covered by an infinity of lines drawn at random, it is evident that the number of these which meet a given finite straight line is proportional to its length, and is the same whatever be its position. Hence, if we take  $l$  the length of the line as the measure of this number, the number of random lines which cut any element  $ds$  of the contour is measured by  $ds$ , and the number which meet the contour is therefore measured by  $\int ds$ , half the length of the boundary. If we take  $2l$  as the measure for the line, the measure for the contour will be  $L$ , as above. Of course we have to remember that each line must meet the contour twice. It would be possible to rectify any closed curve by means of this principle. Suppose it traced on the surface of a circular disk, of circumference  $L$ , and the disk thrown a great number of times on a system of parallel lines, whose distance asunder equals the diameter, if we count the number of cases in which the closed curve meets one of the parallels, the ratio of this number to the whole number of trials will be ultimately the ratio of the circumference of the curve to that of the circle.

dently be the length of an endless string, drawn tight around the contour.

76. If a random line meet a closed convex contour, of length  $L$ , the chance of it meeting another such contour, external to the former, is

$$p = (X - Y)/L,$$

where  $X$  is the length of an endless band enveloping both contours, and crossing between them, and  $Y$  that of a band also enveloping both, but not crossing. This may be shown by means of Legendre's integral above; or as follows:—

Call, for shortness,  $N(A)$  the number of lines meeting an area  $A$ ;  $N(A, A')$  the number which meet both  $A$  and  $A'$ ; then (fig. 8)

$$N(SROQPH) + N(S'Q'OR'T'H') = N(SROQPH + S'Q'OR'T'H') + N(SROQPH, S'Q'OR'T'H'),$$

since in the first member each line meeting both areas is counted twice. But the number of lines meeting the non-convex figure consisting of  $OQPHSR$  and  $OQ'S'H'P'R'$  is equal to the band  $Y$ , and the number meeting both these areas is identical with that of those meeting the given areas  $\Omega, \Omega'$ ; hence

$$X = Y + N(\Omega, \Omega').$$

Thus the number meeting both the given areas is measured by  $X - Y$ . Hence the theorem follows.

77. Two random chords cross a given convex boundary, of length  $L$ , and area  $\Omega$ ; to find the chance that their intersection falls inside the boundary.

Consider the first chord in any position; let  $C$  be its length; considering it as a closed area, the chance of the second chord meeting it is

$$2C/L;$$

and the whole chance of its coordinates falling in  $dp, d\omega$  and of the second chord meeting it in that position is

$$\frac{2C}{L} \frac{dp d\omega}{\iint \frac{dp d\omega}{L}} = \frac{2}{L^2} C dp d\omega.$$

But the whole chance is the sum of these chances for all its positions;

$$\therefore \text{prob.} = 2L^{-2} \iint C dp d\omega.$$

Now, for a given value of  $\omega$ , the value of  $\int C dp$  is evidently the area  $\Omega$ ; then, taking  $\omega$  from  $\pi$  to  $0$ ,

$$\text{required probability} = 2\pi\Omega L^{-2}.$$

The mean value of a chord drawn at random across the boundary is

$$M = \frac{\iint C dp d\omega}{\iint dp d\omega} = \frac{\pi\Omega}{L}.$$

78. A straight band of breadth  $c$  being traced on a floor, and a circle of radius  $r$  thrown on it at random; to find the mean area of the band which is covered by the circle. (The cases are omitted where the circle falls outside the band.)<sup>1</sup>

If  $S$  be the space covered, the chance of a random point on the circle falling on the band is

$$p = M(S)/\pi r^2.$$

This is the same as if the circle were fixed, and the band thrown on it at random. Now let  $A$  (fig. 9) be a position of the random point; the favourable cases are when  $HK$ , the bisector of the band, meets a circle, centre  $A$ , radius  $\frac{1}{2}c$ ; and the whole number are when  $HK$  meets a circle, centre  $O$ , radius  $r + \frac{1}{2}c$ ; hence the probability is

$$p = \frac{2\pi \cdot \frac{1}{2}c}{2\pi(r + \frac{1}{2}c)} = \frac{c}{2r + c}.$$

This is constant for all positions of  $A$ ; hence, equating these two values of  $p$ , the mean value required is

$$M(S) = c(2r + c)^{-1}\pi r^2.$$

The mean value of the portion of the circumference which falls on the band is the same fraction  $\frac{c}{2r + c}$  of the whole circumference.

Fig. 8.

If any convex area whose surface is  $\Omega$  and circumference  $L$  be thrown on the band, instead of a circle, the mean area covered is

$$M(S) = \pi c(L + \pi c)^{-1}\Omega.$$

For as before, fixing the random point at  $A$ , the chance of a random point in  $\Omega$  falling on the band is

$$p = 2\pi \cdot \frac{1}{2}c/L,$$

where  $L'$  is the perimeter of a parallel curve to  $L$ , at a normal distance  $\frac{1}{2}c$  from it. Now

$$L' = L + 2\pi \cdot \frac{1}{2}c.$$

$$\therefore \frac{M(S)}{\Omega} = \frac{\pi c}{L + \pi c}.$$

79. Buffon's problem may be easily deduced in a similar manner. Thus, if  $2r$  = length of line,  $a$  = distance between the parallels, and we conceive a circle (fig. 10) of diameter  $a$  with its centre at the middle  $O$  of the line,<sup>2</sup> rigidly attached to the latter, and thrown with it on the parallels, this circle must meet one of the parallels; if it be thrown an infinite number of times, we shall thus have an infinite number of chords crossing it at random.

Their number is measured by  $2\pi \cdot \frac{1}{2}a$ , and the number which meet  $2r$  is measured by  $4r$ . Hence the chance that the line  $2r$  meets one of the parallels is

$$p = 4r/\pi a.$$

80. To investigate the probability that the inclination of the line joining any two points in a given convex area  $\Omega$  shall lie within given limits. We give here a method of reducing this question to calculation, for the sake of an integral to which it leads, and which is not easy to deduce otherwise.

First let one of the points  $A$  (fig. 11) be fixed; draw through it a chord  $PQ$  =  $C$ , at an inclination  $\theta$  to some fixed line; put  $AP = r$ ,  $AQ = r'$ ; then the number of cases for which the direction of the line joining  $A$  and  $B$  lies between  $\theta$  and  $\theta + d\theta$  is measured by

$$\frac{1}{2}(r^2 + r'^2)d\theta.$$

Now let  $A$  range over the space between  $PQ$  and a parallel chord distant  $dp$  from it, the number of cases for which  $A$  lies in this space and the direction of  $AB$  is from  $\theta$  to  $\theta + d\theta$  is (first considering  $A$  to lie in the element  $dr dp$ )

$$\frac{1}{2}dp d\theta \int_0^C (r^2 + r'^2) dr = \frac{1}{2}C^2 dp d\theta.$$

Let  $p$  be the perpendicular on  $C$  from a given origin  $O$ , and let  $\omega$  be the inclination of  $p$  (we may put  $d\omega$  for  $d\theta$ ),  $C$  will be a given function of  $p, \omega$ ; and, integrating first for  $\omega$  constant, the whole number of cases for which  $\omega$  falls between given limits  $\omega', \omega''$  is

$$\frac{1}{2} \int_{\omega'}^{\omega''} d\omega \int C^2 dp;$$

the integral  $\int C^2 dp$  being taken for all positions of  $C$  between two tangents to the boundary parallel to  $PQ$ . The question is thus reduced to the evaluation of this double integral, which, of course, is generally difficult enough; we may, however, deduce from it a remarkable result; for, if the integral

$$\frac{1}{2} \iint C^2 dp d\omega$$

be extended to all possible positions of  $C$ , it gives the whole number of pairs of positions of the points  $A, B$  which lie inside the area; but this number is  $\Omega^2$ ; hence

$$\iint C^2 dp d\omega = 3\Omega^2,$$

the integration extending to all possible positions of the chord  $C$ ,—its length being a given function of its co-ordinates  $p, \omega$ .

Con. Hence if  $L, \Omega$  be the perimeter and area of any closed convex contour, the mean value of the cub of a chord drawn across it at random is  $3\Omega^2/L$ .

81. Let there be any two convex boundaries (fig. 12) so related that a tangent at any point  $V$  to the inner cuts off a constant segment  $S$  from the outer (e.g., two concentric similar ellipses); let the annular area between them be called  $A$ ; from a point  $X$  taken at random on this annular draw tangents

FIG. 12.

<sup>1</sup> Or the floor may be supposed painted with parallel bands, at a distance under equal to the diameter; so that the circle must fall on one.

<sup>2</sup> The line might be anywhere within the circle, but the probability of its being at a given point is given by the probability of its being at any other point, p. 146. An analytical proof was given by Buffon, *Essai sur la Probabilité*, 1777, p. 177.

XA, XB to the inner. Find the mean value of the arc AB. We shall find

$$M(AB) = LS/A,$$

L being the whole length of the inner curve ABV.

We will first prove the following lemma:—

If there be any convex arc AB (fig. 13), and if  $N_1$  be (the measure of) the number of random lines which meet it once,  $N_2$  the number which meet it twice,

$$2 \text{ arc } AB = N_1 + 2N_2.$$

Fig. 13.

For draw the chord AB; the number of lines meeting the convex figure so formed is

$$N_1 + N_2 = \text{arc} + \text{chord (the perimeter)};$$

but  $N_1$  = number of lines meeting the chord = 2 chord;

$$\therefore 2 \text{ arc} + N_1 = 2N_1 + 2N_2, \therefore 2 \text{ arc} = N_1 + 2N_2.$$

Now fix the point X, and draw XA, XB. If a random line cross the boundary L, and  $p_1$  be the probability that it meets the arc AB once,  $p_2$  that it does so twice,

$$2AB/L = p_1 + 2p_2;$$

and if the point X range all over the annulus, and  $p_1, p_2$  are the same probabilities for all positions of X,

$$2M(AB)/L = p_1 + 2p_2.$$

Let now IK (fig. 14) be any position of the random line; drawing tangents at I, K, it is easy to see that it will cut the arc AB twice when X is in the space marked  $\alpha$ , and once when X is in either space marked  $\beta$ ; hence, for this position of the line,

Fig. 14.

$$p_1 + 2p_2 = \frac{2\alpha + 2\beta}{A} = \frac{2S}{A}, \text{ which is constant; hence } \frac{M(AB)}{L} = \frac{S}{A}.$$

Hence the mean value of the arc is the same fraction of the perimeter that the constant area S is of the annulus.

If L be not related as above to the outer boundary,

$$M(AB)/L = M(S)/A,$$

M(S) being the mean area of the segment cut off by a tangent at a random point on the perimeter L.

The above result may be expressed as an integral. If  $s$  be the arc AB included by tangents from any point  $(x, y)$  on the annulus,

$$\iint s dx dy = LS.$$

It has been shown (*Phil. Trans.*, 1868, p. 191) that, if  $\theta$  be the angle between the tangents XA, XB,

$$\iint \theta dx dy = \pi(A - 2S).$$

The mean value of the tangent XA or XB may be shown to be

$$M(XA) = \frac{S}{2A} P,$$

where P = perimeter of locus of centre of gravity of the segment S.

82. If C be the length of a chord crossing any convex area  $\Omega$ ;  $z, z'$  the areas of the two segments into which it divides the area; and  $p, \omega$  the coordinates of C, viz., the perpendicular on C from any fixed pole, and the angle made by  $p$  with any fixed axis; then

$$\iint C^4 dp d\omega = 6 \iint z z' dp d\omega,$$

both integrations extending to all possible values of  $p, \omega$  which give a line meeting the area.

This identity will follow by proving that, if  $p$  be the distance between two points taken at random in the area, the mean value of  $p$  will be

$$M(p) = \Omega^{-2} \iint z z' dp d\omega. \quad (1),$$

and also

$$M(p) = \frac{1}{6} \Omega^{-2} \iint C^4 dp d\omega. \quad (2).$$

The first follows by considering that, if a random line crosses the area, the chance of its passing between the two points is  $2L^{-1}M(p)$ , L being the perimeter of  $\Omega$ . Again, for any given position of the random line C, the chance of the two points lying on opposite sides of it is  $2zz'\Omega^{-2}$ ; therefore, for all positions of C, the chance is  $2\Omega^{-2}M(zz')$ ; but the mean value  $M(zz')$ , for all positions of the chord, is

$$M(zz') = \frac{\iint z z' dp d\omega}{\iint dp d\omega} = \frac{1}{L} \iint z z' dp d\omega.$$

To prove equation (2), we remark that the mean value of  $p$  is found by supposing each of the points A, B to occupy in succession every possible position in the area, and dividing the sum of their distances in each case by the whole number of cases, the measure of which number is  $\Omega^2$ . Confining our attention to the cases in which the inclination of the distance AB to some fixed direction lies between  $\theta$  and  $\theta + d\theta$ , let the position of A be fixed (fig. 15), and draw through it a chord HH' = C, at the inclination  $\theta$ ; the sum of the cases found by giving B all its positions is

Fig. 15.

$$d\theta \int_0^r p \cdot p dr + d\theta \int_0^{r'} p \cdot p dr = \frac{1}{2} (r^2 + r'^2) d\theta,$$

where  $r = AH$ ,  $r' = AH'$ . Now let A occupy successively all positions between HH' and hh', a chord parallel to it at a distance  $= dp$ ; the sum of all the cases so given will be

$$\frac{1}{2} d\theta dp \int_0^C (r^2 + r'^2) dr = \frac{1}{2} d\theta dp \frac{1}{2} C^3 = \frac{1}{4} d\theta dp C^3.$$

Now, if A moves over the whole area, the sum of the cases will be

$$\frac{1}{4} d\theta \int C^4 dp.$$

where  $p$  = perpendicular on C from any fixed pole O, and the integration extends to all parallel positions of C between two tangents T, T' to the boundary, the inclination of which is  $\theta$ . Removing now the restriction as to the direction of the distance AB, and giving it all values from 0 to  $\pi$ , the sum of all the cases is

$$\frac{1}{4} \int_0^\pi d\theta \int C^4 dp;$$

or, if  $\omega$  = inclination of  $p$ ,  $d\omega = d\theta$ , and the sum is

$$\frac{1}{4} \iint C^4 dp d\omega.$$

The mean value of the reciprocal of the distance AB of two points taken at random in a convex area is easily shown to be

$$M p^{-1} = \Omega^{-2} \iint C^{-2} dp d\omega.$$

Thus, for a circle,

$$M p^{-1} = \frac{16}{3\pi r}.$$

It may also be shown that the mean area of the triangle formed by taking three points A, B, C within any convex area is

$$M(ABC) = \Omega - \Omega^{-3} \iint C^3 z^2 dp d\omega.$$

83. In the last question if we had sought for the mean value of the chord HH' or C, which joins A and B, the sum of the cases when A is fixed and the inclination lies between  $\theta$  and  $\theta + d\theta$  would have been

$$C \cdot \frac{1}{2} (r^2 + r'^2) d\theta,$$

and when A lies between HH' and hh'

$$\frac{1}{2} C d\theta dp \int_0^C (r^2 + r'^2) dr = \frac{1}{2} d\theta dp C^3;$$

and finally, the mean value of C is

$$M(C) = \frac{1}{6} \Omega^{-2} \iint C^4 dp d\omega.$$

Thus the mean value of a chord, passing through two points taken at random within any convex boundary, is double the mean distance of the points.

84. We have now done enough to give the reader some idea of the subject of local probability. We refer him for fuller information to the very interesting work just published by Emanuel Czuber of Prague, *Geometrische Wahrscheinlichkeiten und Mittelwerte*, Leipzig, 1884; also to the *Educational Times Journal*, in which most of the recent theorems on the subject have first appeared in the form of questions, under the able editorship of Mr Miller, who has himself largely contributed. In Williamson's *Integral Calculus*, and a paper by Prof. Crofton, *Phil. Trans.*, 1868, the subject is also treated.

*Literature.*—Besides the works named in the course of this article, see De Morgan's treatise in the *Encyclopedia Metropolitana*; Laurant, *Traité du Calcul des Probabilités*, Paris, 1873; Gouraud, *Histoire du Calcul des Prob.*, Paris, 1848; J. W. L. Glaisher, "On the Law of Facility of Errors of Observations, and the Method of Least Squares," *Trans. R.A.S.*, vol. xxxix.; Cournot, *Théorie des Chances*; Liagre, *Calcul des Prob.*; General Didion, *Calcul des Prob. appliqué au tir des projectiles*. Those who are interested in the metaphysical aspect of the question may consult Boole's *Laws of Thought*, also J. S. Mill's *Logic*. To these and the other works we have named we refer the reader for an account of what we have had to omit, but above all, to the great work of Laplace, on which it is sufficient to say that it is worthy of the genius of its author—the *Théorie analytique des Probabilités*. It is no light task to master the methods and the reasonings there employed; but it is, and will long continue to be, one that must be attempted by all who desire to understand and to apply the theory of probability. (M. W. C.)

PROBATE. See WILL.

PROBUS, MARCUS AURELIUS, Roman emperor from 276 to 282 A.D., was a native of Sirmium on the Save, and son of a military officer of moderate fortune. He early entered the army, where he recommended himself to the emperor Valerian, and against all rule became tribune while still a mere lad. In these times there were abundant opportunities for a capable officer, and Probus served with great distinction in all parts of the empire. Under Aurelian he operated against the Palmyrene realm in Egypt and had a large part in the restoration of Roman authority in the East. On Aurelian's death he was quite the most prominent military officer of Rome, and had a great hold on the troops by his constant care for their comfort, his judicious discipline, and his unselfishness. Tacitus is said to have hesitated to assume the purple which Probus was better fitted to wear, and it is certain that he felt the support of Probus indispensable, and raised him to the rank of commander of the whole East. In a few months the purple actually fell to him, for on the news of Tacitus's death his soldiers at once made him emperor, Florianus, who had claimed to succeed his brother, was put to death by his own troops, and the senate were eager to ratify the choice of the army. The reign of Probus was mainly spent in successful wars by which he re-established the security of all the frontiers; the fiercest and most bloody of these operations was directed to clearing Gaul of the Germans. Probus had also to put down three usurpers, Saturninus, Proculus, and Bonosus. One of his principles was never to allow the soldiers to be idle, and to employ them in time of peace on useful works, such as the planting of vineyards in Gaul, Pannonia, and other districts where a selfish policy had previously forbidden this form of husbandry. This increase of duties was naturally unpopular with the troops, and while the emperor was urging on the draining of the marshes of his native place he was attacked and slain by a sudden mutiny. Scarcely any emperor has left behind him so good a reputation; his death was mourned alike by senate and people, and even the soldiers presently repented and raised a monument in honour of "Probus imperator vere probus." According to the *Chron. Alex.* Probus was fifty years old at the time of his death; he left a family, but they withdrew into private life in northern Italy, and the empire fell to Carus.

PROCESS, in law, denotes in the widest sense of the word any means by which a court of justice gives effect to its authority. In the old practice of the English common law courts process was either original or judicial. Original process was a means of compelling a defendant to compliance with an original writ (see WRIT). Judicial process was any compulsory proceeding rendered necessary after the appearance of the defendant. Process was also divided in civil matters into original, mesne, and final. Original process in this sense was any means taken to compel the appearance of the defendant. A writ of summons is now the universal means in the High Court of Justice. Mesne process was either any proceeding against the defendant taken between the beginning and the end of the action, such as to compel him to give bail, or was directed to persons not parties to the action, such as jurors or witnesses. Arrest on mesne process was abolished in England by the Debtors Act, 1869. Final process is practically coexistent with execution. It includes writs of *fiery facias*, *capias*, *elegit*, sequestration, and attachment. In criminal matters process only applies where the defendant does not appear upon summons or otherwise. A warrant is now the usual form of such process. Service of process on Sunday is void, except in cases of treason, felony, or breach of the peace, 29 Car. II., c. 7. Recent legislation gives facilities for service and execution of

certain kinds of process of the courts of one part of the United Kingdom in another part. Thus by 44 & 45 Vict. c. 24 process of an English court of summary jurisdiction may be served in Scotland, and *vice versa*. A writ of summons in the High Court of Justice may be served out of the jurisdiction in certain cases (*Rules of the Supreme Court*, 1883, Ord. xi.).

*Stet processus* was a technical term used in old common law practice. It consisted of an entry on the record by consent of the parties for a stay of proceedings. Since the Judicature Acts there has been no record, and the *stet processus* has disappeared with it.

In Scotch law process is used in a much wider sense, almost equivalent to practice or procedure in English law. Process in the English sense corresponds rather to diligence. Where papers forming steps of a process are borrowed and not returned, diligence of process caption lies for their recovery.

In the United States process is governed by numerous statutes, both of Congress and of the State legislatures. The law is founded upon the English common law.

PROCIDA, an island less than 2 miles off the west coast of southern Italy between Capo Miseno (or rather Monte Procida) on the mainland and the island of Ischia, forming part of the circondario of Pozzuoli and the province of Naples. Its total area is not much more than 1½ square miles, but it is fertile, well-cultivated, and thickly peopled (10,788 inhabitants in 1871, 10,891 in 1881). Like the neighbouring mainland it is largely of volcanic origin, and the ancient Greek name Prochyte (Προχύτη), Latinized as Procita, possibly refers to this fact. The two fine bays on the south coast are remains of craters, and the soil is almost exclusively tuff. The coasts are usually a rocky scarp; the general surface of the island is comparatively low and flat. Procida, the chief town, lies on the isthmus of a peninsula, at the landward extremity, looking out over a spacious bay. It contains a castle, now used as a prison, and an old royal palace of the Bourbons, who had a hunting park in the island; and the harbour is defended by a fort. In the Piazza dei Martiri is a monument to the twelve who were executed as political offenders in 1799. The islanders are mainly engaged in market-gardening, vine-growing, the fisheries, and the coasting trade; but the number of fishing-boats belonging to Procida is much smaller than it used to be. In accordance with their claim to be of Greek descent the women are accustomed to wear on the festival of St Michael a picturesque Greek costume and to dance the tarantula.

In the 13th century the island was the feudal possession of Giovanni da Procida, the chief conspirator in the Sicilian Vespers. The capture off the coast, by the Ottoman fleet, of a number of Andrea Doria's galleys in 1522 was the last of many instances in which Procida was made to realize the hostility of Mohammedan powers. In 1799, from 1806 to 1809, and again in 1813 it was occupied by the English.

PROCLUS. See NEOPLATONISM.

PROCONSUL. See CONSUL, vol. vi. p. 315, and PROVINCE.

PROCOPIUS, the most eminent historian of the Eastern Roman empire, was born at Cæsarea in Palestine, then one of the chief cities of the Roman East, towards the end of the 5th century, probably between 485 and 495 A.D. Of his family and earlier life nothing is known, but it has been plausibly conjectured from the aristocratic sympathies he manifests that he belonged to one of the better families of his city, and from the place of his birth that he was educated at the great law school of Berytus (Beirut). He became a lawyer, probably at Constantinople, and was in 526 appointed σύμβουλος to Belisarius, who was proceeding to command the imperial army in the war against the Persians (*Proc. Pers.*, i. 12). The chief duties of this office, which is also described as that of *πάρεδρος* or *συγκάθεδρος*, seem to have been the giving of legal advice to the general,

who had a measure of judicial as well as administrative power, and have been well compared by Mr Hodgkin (*Italy and Her Invaders*, vol. iii. p. 638) to those of an English judge advocate. When the Persian War was suspended Procopius probably returned with his general to Constantinople; and when Belisarius was despatched against the Vandals of Africa in 533 Procopius again accompanied him, as he subsequently did in the war against the Ostrogoths of Italy which began in 536. Whether he held the same position of legal assessor through these campaigns or was merely a member of the large personal following which Belisarius had we do not know. Suidas calls him the secretary (*ὑπογραφεύς*) of Belisarius, but this may be merely a reference to his original appointment as *σύμβουλος* in the Persian campaign. He was evidently much valued by Belisarius, who twice employed him on difficult and important missions—once in 533 to obtain from Syracuse provisions for the Roman fleet and information as to the preparations of the Vandals, and again in 537, when the historian was despatched from Rome, which Belisarius was holding against the Goths, to collect troops and corn in Campania and bring them in a fleet to Ostia. On both occasions Procopius acquitted himself with skill and success. He passes lightly over his own performances, and nowhere strikes us as eager for an opportunity of singing his own praises.

After the capture of Ravenna in 539 Procopius would seem to have returned to Constantinople, where he was in 542, the year of the great plague, which he has minutely described (*Pers.*, ii. 22). It does not appear whether he was with the Roman armies in the later stages of the Gothic War, when Belisarius and afterwards Narses fought against Totila in Italy, though his narrative of these years is so much less full and minute than that of the earlier warfare that probably he was not an eye-witness of these campaigns. Of his subsequent fortunes we know nothing, except that he was living in 559. He was an advocate by profession (Agathias, Evagrius, and other Byzantine writers call him *ῥήτωρ*), but whether he practised law after his return from the Italian wars may be doubted, for he must have been then occupied with the composition of his histories, and his books show that he spent a good deal of time in travel. He seldom refers to legal matters, and shows little interest in them, mentioning only in the most cursory way the legislation and codification of Justinian. Whether he was the Procopius who was prefect of Constantinople in 562 (Theophanes, *Chronographia*, 201, 202) and was removed from office in the year following cannot be determined. Little can be founded on the name, for it was a common one in that age, and had this Procopius been our historian one might have expected some of the subsequent writers who refer to the latter to have mentioned this fact about him. On the other hand the historian was evidently a person of note, who had obtained the rank of *Illustis* (Suidas calls him *Ἰλλούστριος*), and a passage in the *Anecdota* looks as if he had risen to be a senator (*Anecd.*, c. 12), so that there is no improbability in his having been raised to the high office of prefect.

There has been some controversy as to his religion. So far as external profession went, he must have been a Christian; for paganism, persecuted by Justinian, would hardly have been tolerated in so conspicuous a person; nor is there any evidence for his being a heathen other than the cool indifference with which (except in the *De Edificiis*) he speaks about Christian beliefs and practices. He seems to have been so far a Christian as to have believed in a God and have held Christ to be a supernatural being, but he frequently expresses himself in sceptical language, talks of God and Fate as if practically synonymous, and entertained great contempt for the theological controversies which raged so hotly in his own time.

Procopius's writings fall into three divisions—the *Histories* (Persian, Vandal, and Gothic Wars) in eight books, the treatise on the *Buildings of Justinian* (*De Edificiis*) in six books, and the *Unpublished Memoirs* (τὰ Ἀνέκδοτα, *Historia Arcana*), here cited as the *Anecdota*.

The *Histories* are called by the author himself the *Books about the Wars* (οἱ ὑπὲρ τῶν πολέμων λόγοι). They consist of—(1) the Persian Wars, in two books, giving a narrative of the long struggle of the emperors Justin and Justinian against the Persian kings Kobad and Chosroes Anushirvan down to 550; (2) the Vandal War, in two books, describing the conquest of the Vandal kingdom in Africa and the subsequent events there from 532 down to 546 (with a few words on later occurrences); (3) the Gothic War, in four books, narrating the war against the Ostrogoths in Sicily and Italy from 536 till 552. These three treatises were written continuously to form one connected history; but, as the arrangement of events is geographical, not chronological, they overlap in time, the Persian War carrying its narrative over a large part of the period embraced in the Vandal War and the Gothic War. The fourth and last of the four books of the Gothic War is really a general history of the empire, designed to continue the Persian War as well as the Gothic. It was written after the year in which the preceding seven books had been published, and was itself published apparently in 554 or 555. These eight books of *Histories*, although mainly occupied with military matters, contain notices of some of the more important domestic events, such as the Nika insurrection at Constantinople in 532, the plague in 542, the conspiracy of Artabanes in 548. They tell us, however, comparatively little about the civil administration of the empire, and nothing about legislation. On the other hand they are rich in geographical and ethnographical information, often of the highest value for our knowledge of the barbarian and particularly of the Teutonic tribes who lived on the borders of the empire and were either its enemies or the material of its armies.

As an historian, Procopius would have deserved honour in any age, and is of quite unusual merit when one considers the generally low literary level of the age which produced him. From the 4th to the 15th century the Eastern empire has no lay writer of gifts approaching his. He is industrious in collecting facts, careful and impartial in stating them; his judgment is sound, his reflexions generally acute, his conceptions of the general march and movement of things not unworthy of the great events he has recorded. His descriptions, particularly of military operations, are clear, and his especial fondness for this part of the subject seldom leads him into unnecessary minuteness. The style, although marked by mannerisms, by occasional affectations and rhetorical devices, is on the whole direct and businesslike, nor is the Greek bad, when one considers the time. Thucydides and Herodotus are the two models whom he keeps always before his eyes: he imitates the former in the maxims (*γνώμαι*) he throws in, and the speeches which he puts into the mouth of the chief actors; the latter in his frequent geographical digressions, in the personal anecdotes, in the tendency to collect and attach some credence to marvellous tales. It need hardly be said that he falls far short of the vigour and profundity of the Attic, as well as of the genial richness, the grace, the simplicity, the moral elevation, the poetical feeling of the Ionic historian. The speeches are obviously composed by Procopius himself, rarely showing any dramatic variety in their language, but they seem sometimes to convey the substance of what was said, and even when this is not the case they frequently serve to bring out the points of a critical situation. The geographical and ethnological notices are precious. Procopius is almost as much a geo-

grapher as an historian—it is one of his merits to have perceived the importance of each science to the other—and his descriptions of the peoples and places he himself visited are generally careful and thorough. Although a warmly patriotic Roman, he does full justice to the merits of the barbarian enemies of the empire, and particularly of the Ostrogoths; although the subject of a despotic prince, he criticizes the civil and military administration of Justinian and his dealings with foreign peoples with a freedom which gives a favourable impression of the tolerance of the emperor. His chief defects are a somewhat pretentious and at the same time monotonous style, and a want of sympathy and intensity, which prevents him from giving full life and reality to the personages who figure in his narrative, or raising it to a level worthy of the great and terrible scenes which he has sometimes to describe.

The *De Edificiis*, or treatise on the Buildings of Justinian, contains an account of the chief public works executed during the reign of the emperor down to 558, in which year it seems to have been composed, particularly churches, palaces, hospitals, fortresses, roads, bridges and other river works. All these are of course ascribed to the personal action of the monarch. The treatise is a little longer than the average length of one single book of the eight books of the *Histories*. Its arrangement is geographical; beginning from Constantinople, it describes works executed in the Mesopotamian provinces, in Armenia and the Caucasian countries, in Thrace and Macedonia, in Asia Minor and Syria, in Egypt and Africa as far as the Pillars of Hercules. If not written at the command of Justinian (as some have supposed), it is at any rate semi-official, being evidently grounded on official information, and is full of gross flattery of the emperor and of the (then deceased) empress. In point of style it is greatly inferior to the *Histories*—florid, pompous, and affected, and at the same time tedious. Its chief value lies in the geographical notices which it contains.

The *Anecdota*, or Secret History, in length almost equal to the *De Edificiis*, and somewhat shorter than the average length of a book of the *Histories*, purports to be a supplement to these, containing explanations and additions which the author could not place in the *Histories* for fear of Justinian and Theodora. It is a furious invective against these sovereigns, their characters, personal conduct, and government, with attacks on Belisarius and his wife Antonina, and on other official persons of note in the civil and military services of the empire—attacks whose effect is weakened by the passion the author betrays. Frequent references to the *Histories* are interspersed, but the events of the wars are seldom referred to, the main topic being the personal and official misdeeds of the rulers as shown in domestic affairs. The ferocity and brutality of this scandalous chronicle astonish us, for modern writings of the same order have usually been the work of vulgar and anonymous scribblers, not of an able, accomplished, and highly placed man such as Procopius was. Hence its authenticity has been often called in question, and a few words are needed both on that question and on the further question of the credibility of its contents.

It was unknown to Agathias and Evagrius, younger contemporaries of Procopius who frequently mention his *Histories*, and is first referred to by Suidas (writing in the 10th century), who ascribes it to Procopius. Two MSS. (since lost) are mentioned as having been brought to Italy in the days of the Renaissance, but the first publication was made by Nicholas Alemanni, an official of the Vatican, who found a MS. in that library and edited it with copious and learned notes and a Latin translation (Lyons, 1623). Since his day several jurists (led thereto by jealousy for

Justinian's reputation) and other scholars have denied it to be the work of Procopius, among whom it is sufficient to refer to the latest, J. H. Reinkens.<sup>1</sup> The external argument against its genuineness, drawn from its not being mentioned till four centuries after the death of Procopius, appears weak when we recollect that it was obviously not written to be published at the time, and may well have remained concealed for generations. The internal argument from the difference between the view of Justinian it presents and that given in the *De Edificiis* will impress no one who has observed the almost patent insincerity of the latter book, and the censure, severe though carefully guarded, which the *Histories* frequently bestow on Justinian's policy. On the other hand the agreement in many points of fact between the *Histories* and the *Anecdota*, and the exactness of the references from the latter to the former, point to unity of authorship; while the similarity of opinions, ideas, beliefs, prejudices, and still more the similarities of literary manner, style, and language, supply an overwhelming body of evidence that the *Anecdota* are a genuine, and so far as his deep-seated feelings go the most genuine, work of Procopius. The question, which ought never to have been deemed doubtful, has been set at rest by the careful comparison of the use of words and phrases in the acknowledged works of Procopius and in the *Anecdota*, which we owe to the industry of Dr Felix Dahn, and which is set forth in his excellent book mentioned at the close of this article. It is less easy to pronounce on the credibility of the picture which the *Anecdota* give of the court and government of Justinian. Plainly there are many exaggerations and some absurdities; yet, when we find some of the severest statements of the book confirmed by other annalists and others substantially tallying with or explaining those made by Procopius himself in the *Histories*, we are led to conclude that there is a substantial basis of fact for the charges it brings. It is of course often difficult, sometimes impossible, to say what deductions must be made from the form these charges take; but after studying the book closely one becomes rather less than more sceptical.

In point of style, the *Anecdota* are inferior to the *Histories*, and have the air of being unfinished or at least unrevised. Their merit lies in the furious earnestness with which they are written, and which gives them a force and reality sometimes wanting in the more elaborate books written for publication.

The character of a man who could revenge himself for having been obliged to bestow gross flattery on his sovereign by ferocious invective meant to be launched after his death inspires little respect. Otherwise Procopius is a favourable specimen of his age. He is patriotic, with a strong feeling for the greatness of the empire, its dignity, the preservation of its ancient order. He is a worshipper of the past, whose ideal is such a government as that of Trajan or Hadrian. His ethical standard is scarcely affected by Christianity, but is that of a Greek of classical times, with too great a tolerance of deceit when practised against barbarian enemies, and doubtless also with a deficient sense of honour and personal independence. Yet his patriotism does not prevent him from doing justice to the valour of the Persians, or the still finer qualities of the Goths as he had learnt to know them in Italy. He is, however, frigid in sentiment as well as in style, and throws little geniality into his narratives and descriptions. In his attitude towards the unseen world he is at once sceptical and superstitious—sceptical in that he speaks with equal hesitation about the practices

<sup>1</sup> *Anecdota sicut scripta a Procopio Cæsariensi inquiruntur*, Breslau, 1858.

and doctrines of different faiths, and declares his persuasion that nothing more can be known about God than that He is all-wise and all-powerful; superstitious in his readiness to accept all kinds of marvels, omens, prophecies, apparitions, and to find in the sudden changes of human affairs the action of a spiteful fortune which delights to startle men and confound their schemes. Procopius has little philosophy in his history; he is a vague and inconsistent thinker, and is strongest when he is describing events or facts, or drawing such direct inferences from them as strike an acute man of the world.

The best edition of Procopius is that by Dindorf in the *Corpus Scriptorum Historiæ Byzantinæ*, 3 vols., Bonn, 1833-38. The best criticisms and examinations of his writings are those by W. S. Teuffel, in his *Studien und Charakteristiken zur Literaturgeschichte*, Leipzig, 1871; and F. Dahn, *Procopius von Cæsarea*, Berlin, 1865. (J. BR.)

**PROCOPIUS.** Two leaders of this name are mentioned in connexion with the wars of the HUSSITES (*q.v.*).

**I. ANDREAS PROCOPIUS**, surnamed "the Great" or "the Bald," was a native of Bohemia, born about 1380. He had travelled extensively in Europe, and had even visited Jerusalem before he received priestly orders. On the outbreak of the Hussite War he joined Zizka, and was chosen to succeed him after his death in 1425. From 1426 onwards he met with a succession of military successes in Austria, Moravia, Silesia, and Hungary which compelled various potentates to purchase peace, and disposed even the council of Basel to a spirit of compromise. Procopius and his "Taborites" were, however, dissatisfied with the "Compactata" which the "Calixtines" accepted, and resolved to carry on the contest. He perished in the decisive battle fought near Böhmschbrod on May 30, 1434.

**II. Of PROCOPIUS** surnamed "the Little" nothing is known save that he co-operated with Procopius "the Great" from 1427 onwards, and that he shared his fate.

**PROCTER, BRYAN WALLER** (1787-1874), poet and miscellaneous writer, was born on the 21st November 1787. At an early age he was sent to a small boarding school near London, and thence in his thirteenth year to Harrow, where he had for contemporaries Lord Byron and Sir Robert Peel. On leaving school he was placed in the office of a solicitor at Calne, Wiltshire, remaining there until about 1807, when he returned to pursue his legal studies in London. By the death of his father in 1816 he became possessed of a small property, and soon after entered into partnership with a solicitor; but in 1820 the partnership was dissolved, and during the temporary difficulties thus occasioned he supported himself in part by literary work under the pseudonym of Barry Cornwall. After his marriage in 1824 to Miss Skepper, a daughter of Mrs Basil Montagu, he returned to his professional work as conveyancer, and was called to the bar in 1831. In the following year he was appointed metropolitan commissioner of lunacy—an appointment annually renewed until his election to the permanent commission constituted by the Act of 1842. He resigned office in 1861. During the last years of his life a failure of speech led him to withdraw increasingly from society, and his death took place on October 4, 1874. The period of his poetic productiveness had closed many years previously, the larger proportion of his verse having been composed between 1815, when he began to contribute to the *Literary Gazette*, and 1823, or at latest 1832.

His principal works in the verse form were—*Dramatic Scenes and other Poems* (1819), *A Sicilian Story* (1820), *Mirandola*, a tragedy performed at Covent Garden with Maeready, Charles Kemble, and Miss Foote in the leading parts (1821), *The Flood of Thessaly* (1823), and *English Songs* (1832). He was also the author of *Effigies Poeticæ* (1824), *Life of Edmund Kean* (1835), *Essays and Tales in Prose* (1851), *Charles Lamb; a Memoir* (1866), and of memoirs of Ben Jonson and Shakespeare for editions of their works.

A posthumous autobiographical fragment with notes of his literary friends, of whom he had a wide range from Bowles to Browning, was published in 1877. His genius cannot be said to have been entirely mimetic, but his works are full of subdued echoes. His songs have caught some notes from the Elizabethan and Cavalier lyrics, and blended them with others from the leading poets of his own time; and his dramatic fragments show a similar infusion of the early Victorian spirit into pre-Restoration forms and cadences. The results are somewhat heterogeneous, and without the impress of a pervading and dominant personality to give them unity, but they abound in pleasant touches, with here and there the flash of a higher, though casual, inspiration.

His daughter, **ADELAIDE ANNE PROCTER** (1825-1864), also attained some distinction as a poet, her principal works being her *Legends and Lyrics*, of which a first series, published in 1858, ran through nine editions in seven years, and a second series issued in 1860 met with a similar success. Her unambitious verses dealing with simple emotional themes in a simple manner have a charm which is scarcely explicable on the ground of high literary merit, but which is due rather to the fact that they are the cultured expression of an earnest and beneficent life. Latterly she became a convert to Roman Catholicism, and her philanthropic zeal appears to have hastened her death, which took place February 3, 1864.

**PROCTOR**, the English form of the Latin *procurator*, denotes a person who acts for another, and so approaches very nearly in meaning to **AGENT** (*q.v.*). The word is used in three senses. (1) A particular kind of university official. (2) A representative of the clergy in convocation. A proctor represents either the chapter of a cathedral or the beneficed clergy of a diocese. In the province of Canterbury two proctors represent the clergy of each diocese; in that of York there are two for each archdeaconry. In both alike each chapter is represented by one. (3) A practitioner in the ecclesiastical and admiralty courts. A proctor is a qualified person licensed by the archbishop of Canterbury to undertake duties such as are performed in other courts by solicitors. The word in this sense is now only of historical interest. The effect of recent legislation is that all the business formerly confined to proctors may now be conducted by solicitors. The instrument by which a procurator or proctor is appointed is called a *proxy*, a term also applied to the representative himself. Proxies are still in use in bankruptcy and in some of the Vice-Admiralty Courts. Formerly peers could give their vote in parliament by proxy, but this right was discontinued by the standing order of March 31, 1868. A shareholder in a joint-stock company may vote by proxy. A proxy must, by the Stamp Act, 1870, bear a penny stamp.

There are no proctors in the United States. In Scotland the original term procurator is used to denote a law agent who practises in an inferior court. A procurator has been, since the Law Agents Act, 1873, exactly in the same legal position as other law agents. The procurator-fiscal is a local officer charged with the prosecution of crimes. He is appointed by the sheriff. He also performs the duties of an English coroner by holding inquiries into the circumstances of suspicious deaths.

**PRODICUS** of Ceos, whose birth is conjecturally assigned to 465-460 B.C., was a humanist of the first period of the Sophistical movement. He was still living in 399 B.C. Visiting Athens, in the first instance (it is said) as the accredited agent of his native island, he became known in the intellectual capital as a good speaker and a successful teacher. Like Protagoras, he professed to train his pupils for domestic and civic affairs; but it would appear that, while Protagoras's chief instruments of education were rhetoric and style, Prodicus made ethics prominent in his curriculum. As a moralist he seems to have been orthodox, neither impugning nor developing traditional notions. In his literary teaching he laid special stress upon distinctions in the use of words. The Platonic Socrates (as well as Aristophanes) speaks of Prodicus with a certain respect, earned perhaps by his simple though conventional morality; but it is easy to see that Plato thought him affected and pedantic, and did not rank him either with Protagoras as a thinker or with Gorgias as

a stylist. Two of Prodicus's discourses were especially famous: one, "on propriety of language," is repeatedly alluded to by Plato; the other, entitled *ἑρμῆς*, contained the celebrated apologue of the choice of Heracles, of which the Xenophontean Socrates (*Mem.*, ii. 1, 21 sq.) gives a summary. Theramenes, Euripides, and Isocrates are said to have been pupils or hearers of Prodicus. For some personal traits, and a caricature of his teaching, see Plato's *Protagoras*, 315 C sq., 337 A sq.

On the Sophistical movement, as well as for bibliographical information, see SOPHISTS.

PROHIBITION is defined by Blackstone as "a writ directed to the judge and parties of a suit in any inferior court, commanding them to cease from the prosecution thereof, upon a surmise either that the cause originally or some collateral matter arising therein does not belong to that jurisdiction, but to the cognizance of some other court." A writ of prohibition is a prerogative writ—that is to say, it does not issue as of course, but is granted only on proper grounds being shown. Before the Judicature Acts prohibition was granted by one of the Superior Courts at Westminster; it also issued in certain cases from the Court of Chancery. It is now granted by the High Court of Justice. Up to 1875 the High Court of Admiralty was for the purposes of prohibition an inferior court. But now by the Judicature Act, 1873, 36 & 37 Vict. c. 66, § 24, it is provided that no proceeding in the High Court of Justice or the Court of Appeal is to be restrained by prohibition, a stay of proceedings taking its place where necessary. The Admiralty Division being now one of the divisions of the High Court can therefore no longer be restrained by prohibition. The courts to which it most frequently issues in the present day are the ecclesiastical courts, and county and other local courts, such as the Lord Mayor's Court of London, the Court of Passage of the city of Liverpool, and the Court of Record of the hundred of Salford. In the case of courts of quarter sessions, the same result is generally obtained by *certiorari*. The extent to which the ecclesiastical courts were restrainable by prohibition led to continual disputes for centuries between the civil and ecclesiastical authorities. Attempts were made at different times to define the scope of the writ, the most conspicuous instances being the statute *Circumspecte Agatis*, 13 Edw. I. st. 4; the *Articuli Cleri*, 9 Edw. II. st. 1; and the later *Articuli Cleri* of 3 Jac. I., consisting of the claims asserted by Archbishop Bancroft and the reply of the judges. The law seems to be undoubted that the spiritual court acting in spiritual matters *pro salute animæ* cannot be restrained. The difficulties arise in the application of the principle to individual cases.

Prohibition lies either before or after judgment. In order that proceedings should be restrained after judgment it is necessary that want of jurisdiction in the inferior court should appear upon the face of the proceedings, that the party seeking the prohibition should have taken his objection in the inferior court, or that he was in ignorance of a material fact. A prohibition goes either for excess of jurisdiction, as if an ecclesiastical court were to try a claim by prescription to a pew, or for transgression of clear laws of procedure, as if such a court were to require two witnesses to prove a payment of tithes. It will not as a rule be awarded on a matter of practice. The remedy in such a case is appeal. Nor will it go, unless in exceptional cases, at the instance of a stranger to the suit. The procedure in prohibition is partly common law, partly statutory. By 50 Edw. III. c. 4 prohibition is not to be awarded after consultation, i.e., after the judges of the superior court have remitted the case as within the jurisdiction of the inferior court. 1 Will. IV. c. 21 (an Act to improve the proceedings in prohibition and on writs of

mandamus) was repealed as to England by 46 & 47 Vict. c. 49, but it still applies to Ireland, to which it was extended by 9 & 10 Vict. c. 113. Application for a prohibition is usually made *ex parte* to a judge in chambers on affidavit. The application may be granted or refused. If granted, a rule to show cause why a writ of prohibition should not issue goes to the inferior judge and the other party. In prohibition to courts other than county courts pleadings in prohibition may be ordered. These pleadings are as far as possible assimilated to pleadings in actions. They are rare in practice, and are only ordered in cases of great difficulty and importance. In prohibition to county courts they cannot be ordered, 19 & 20 Vict. c. 108, § 42. Further statutory regulations as to prohibition to county courts are contained in §§ 40, 41, and 44 of the same Act, and in 13 & 14 Vict. c. 61, § 22. Much learning on the subject of prohibition will be found in the opinion of Mr Justice Wills delivered to the House of Lords in *The Mayor and Aldermen of London v. Cox* (*Law Reports*, 2 Eng. and Ir. Appeals, 239).

In Scotch law prohibition is not used in the English sense. The same result is obtained by suspension or reduction. In the United States the supreme court has power to issue a prohibition to the district courts when proceeding as courts of admiralty and maritime jurisdiction. Most of the States have also their own law upon the subject, generally giving power to the supreme judicial authority in the State to prohibit courts of inferior jurisdiction.

PROJECTILES. See MECHANICS (vol. xv. pp. 682 sq., 706 sq.) and GUNNERY.

PROJECTION. If from a fixed point S in space lines or rays be drawn to different points A, B, C, . . . in space, and if these rays are cut by a plane in points A', B', C', . . . the latter are called the projections of the given points on the plane. Instead of the plane another surface may be taken, and then the points are projected to that surface instead of to a plane. In this manner any figure, plane or in space of three dimensions, may be projected to any surface from any point which is called the centre of projection. If the figure projected is in three dimensions then this projection is the same as that used in what is generally known as *perspective*.

In modern mathematics the word *projection* is often taken with a slightly different meaning, supposing that plane figures are projected into plane figures, but three-dimensional ones into three-dimensional figures. Projection in this sense, when treated by coordinate geometry, leads in its algebraical aspect to the theory of linear substitution and hence to the theory of invariants and co-variants.

In this article projection will be treated from a purely geometrical point of view.

We shall first and principally treat of the projection of plane figures into plane figures, and consider a number of special cases due to special positions of the two planes or of the centre of projection. We shall next consider the representation of figures of three dimensions by plane figures (orthographic projections, drawing in plan and elevation, &c.), then treat of perspective in its ordinary sense, and speak shortly of projections to curved surfaces.

References like (G. § 87) relate to section II. of the article GEOMETRY, vol. x. pp. 388 sq.

§ 1. PROJECTION OF PLANE FIGURES.—Let us suppose we have in space two planes  $\pi$  and  $\pi'$ . In the plane  $\pi$  a figure is given having known properties; then we have the problem to find its projection from some centre S to the plane  $\pi'$ , and to deduce from the known properties of the given figure the properties of the new one.

If a point A is given in the plane  $\pi$  we have to join it to the centre S and find the point A' where this ray SA cuts the plane  $\pi'$ ; it is the projection of A. On the other hand if A' is given in the plane  $\pi'$ , then A will be its projection in  $\pi$ . Hence if one figure in  $\pi'$  is the projection of another in  $\pi$ , then conversely the latter is also the projection of the former.

A point and its projection are therefore also called corresponding points, and similarly we speak of corresponding lines and curves, &c.

§ 2. We at once get the following properties:—

*The projection of a point is a point, and one point only.*

*The projection of a line (straight line) is a line; for all points in a line are projected by rays which lie in the plane determined by S and the line, and this plane cuts the plane  $\pi$  in a line which is the projection of the given line.*

*If a point lies in a line its projection lies in the projection of the line.*

*The projection of the line joining two points A, B is the line which joins the projections A', B' of the points A, B. For the projecting plane of the line AB contains the rays SA, SB which project the points A, B.*

*The projection of the point of intersection of two lines  $a, b$  is the point of intersection of the projections  $a', b'$  of those lines.*

Similarly we get—

*The projection of a curve will be a curve.*

*The projections of the points of intersection of two curves are the points of intersection of the projections of the given curves.*

*If a line cuts a curve in  $n$  points, then the projection of the line cuts the projection of the curve in  $n$  points. Or*

*The order of a curve remains unaltered by projection.*

*The projection of a tangent to a curve is a tangent to the projection of the curve. For the tangent is a line which has two coincident points in common with a curve.*

*The number of tangents that can be drawn from a point to a curve remains unaltered by projection. Or*

*The class of a curve remains unaltered by projection.*

*Example.*—The projection of a circle is a curve of the second order and second class.

§ 3. Two figures of which one is a projection of the other obtained in the manner described may be moved out of the position in which they are obtained. They are then still said to be one the projection of the other, or to be projective or homographic. But when they are in the position originally considered they are said to be in *perspective position*, or (shorter) to be *perspective*.

All the properties stated in §§ 1, 2 hold for figures which are projective, whether they are perspective or not. There are others which hold only for projective figures when they are in perspective position, which we shall now consider.

If two planes  $\pi$  and  $\pi'$  are perspective, then their line of intersection is called the *axis of projection*. Any point in this line coincides with its projection. Hence

*All points in the axis are their own projections. Hence also*

*Every line meets its projection on the axis.*

The property that the lines joining corresponding points all pass through a common point, that any pair of corresponding points and the centre are in a line, is also expressed by saying that the figures are *co-linear*; and the fact that both figures have a line, the axis, in common on which corresponding lines meet is expressed by saying that the figures are *co-axial*.

The connexion between these properties has to be investigated.

For this purpose we consider in the plane  $\pi$  a triangle ABC, and let the lines BC, CA, AB be denoted by  $a, b, c$ . The projection will consist of three points A', B', C' and three lines  $a', b', c'$ . These have such a position that the lines AA', BB', CC' meet in a point, viz., at S, and the points of intersection of  $a$  and  $a'$ ,  $b$  and  $b'$ ,  $c$  and  $c'$  lie on the axis (by § 2). The two triangles therefore are said to be both *co-linear* and *co-axial*. Of these properties either is a consequence of the other, as will now be proved.

§ 4. **DESARGUE'S THEOREM.**—If two triangles, whether in the same plane or not, are co-linear they are co-axial. Or

*If the lines AA', BB', CC' joining the vertices of two triangles meet in a point, then the intersections of the sides BC and B'C', CA and C'A', AB and A'B' are three points in a line. Conversely,*

*If two triangles are co-axial they are co-linear. Or*

*If the intersection of the sides of two triangles ABC and A'B'C', viz., of BC and B'C', of CA and C'A', and of AB and A'B', lie in a line, then the lines AA', BB', and CC' meet in a point.*

*Proof.*—Let us first suppose the triangles to be in different planes. By supposition the lines AA', BB', CC' (fig. 1) meet in a point S. But three intersecting lines determine three planes, SBC, SCA, and SAB. In the first lie the points B, C and also B', C'. Hence the lines BC and B'C' will intersect at some point P, because any two lines in the same plane intersect. Similarly CA and C'A' will intersect at some point Q, and AB and A'B' at some point R. These points P, Q, R lie in the plane of the triangle ABC because they are points on the sides of this triangle, and similarly in the plane of the triangle A'B'C'. Hence they lie in the intersection of two planes,—that is, in a line.

Fig. 1.

Secondly, If the triangles ABC and A'B'C' lie both in the same plane, the above proof does not hold. In this case we may consider the plane figure as the projection of the figure in space of which we have just proved the theorem. Let ABC, A'B'C' be the co-linear triangles with S as centre, so that AA', BB', CC' meet at S. Take now any point in space, say your eye E, and from it draw the rays projecting the figure. In the line ES take any point S<sub>1</sub>, and in EA, EB, EC take points A<sub>1</sub>, B<sub>1</sub>, C<sub>1</sub> respectively, but so that S<sub>1</sub>, A<sub>1</sub>, B<sub>1</sub>, C<sub>1</sub> are not in a plane. In the plane ESA which projects the line S<sub>1</sub>A<sub>1</sub> fix then the line S<sub>1</sub>A<sub>1</sub> and also EA'; these will therefore meet in a point A'<sub>1</sub>, of which A' will be the projection. Similarly points B'<sub>1</sub>, C'<sub>1</sub> are found. Hence we have now in space two triangles A<sub>1</sub>B<sub>1</sub>C<sub>1</sub> and A'<sub>1</sub>B'<sub>1</sub>C'<sub>1</sub> which are co-linear. They are therefore co-axial, that is, the points P<sub>1</sub>, Q<sub>1</sub>, R<sub>1</sub>, where A<sub>1</sub>B<sub>1</sub> &c., meet will lie in a line. Their projections therefore lie in a line. But these are the points P, Q, R, which were to be proved to lie in a line.

This proves the first part of the theorem. The second part or converse theorem is proved in exactly the same way. For another proof see (G. § 37).

§ 5. By aid of Desargue's theorem we can now prove a fundamental property of two projective planes.

Let  $s$  be the axis, S the centre, and let A, A' and B, B' be two pairs of corresponding points which we suppose fixed, and C, C' any other pair of corresponding points. Then the triangles ABC and A'B'C' are co-axial, and they will remain co-axial if the one plane  $\pi$  be turned relative to the other about the axis. They will therefore, by Desargue's theorem, remain co-linear, and the centre will be the point S', where AA' meets BB'. Hence the line joining any pair of corresponding points C, C' will pass through the centre S'. The figures are therefore perspective. This will remain true if the planes are turned till they coincide, because Desargue's theorem remains true.

**THEOREM.**—If two planes are perspective, then if the one plane be turned about the axis through any angle, especially if the one plane be turned till it coincides with the other, the two planes will remain perspective; corresponding lines will still meet on a line called the axis, and the lines joining corresponding points will still pass through a common centre S situated in the plane.

*Whilst the one plane is turned this point S will move in a circle whose centre lies in the plane  $\pi$ , which is kept fixed, and whose plane is perpendicular to the axis.*

The last part will be proved presently. As the plane  $\pi'$  may be turned about the axis in one or the opposite sense, there will be two perspective positions possible when the planes coincide.

§ 6. Let (fig. 2)  $\pi, \pi'$  be the planes intersecting in the axis  $s$  whilst S is the centre of projection.

To project a point A in  $\pi$  we join A to S and see where this line cuts  $\pi'$ . This gives the point A'. But if we draw through S any line parallel to  $\pi$ , then this line will cut  $\pi'$  in some point I', and if all lines through S be drawn which are parallel to  $\pi$  these will form a plane parallel to  $\pi$  which will cut the plane  $\pi'$  in a line  $i'$  parallel to the axis  $s$ . If we say that a line parallel to a plane cuts the latter at an infinite distance, we may say that all points at an infinite distance in  $\pi$  are projected into points which lie in a straight line  $i'$ , and conversely all points in the line are projected to an infinite distance in  $\pi$ , whilst all other points are projected to finite points. We say therefore that all points in the plane  $\pi$  at an infinite distance may be considered as lying in a straight line, because their projections lie in a line. Thus we are again led to consider points at infinity in a plane as lying in a line (comp. G. §§ 2-4).

Similarly there is a line  $j$  in  $\pi$  which is projected to infinity in  $\pi'$ ; this projection shall be denoted by  $j'$  so that  $i$  and  $j'$  are lines at infinity.

§ 7. If we suppose through S a plane drawn perpendicular to the axis  $s$  cutting it at T, and in this plane the two lines SI' parallel to  $\pi$  and SJ parallel to  $\pi'$ , then the lines through I' and J parallel to the axis will be the lines  $i'$  and  $j'$ . At the same time a parallelogram SJTI' has been formed. If now the plane  $\pi'$  be turned about the axis, then the points I' and J will not move in their planes; hence the lengths TJ and TI', and therefore also SI' and SJ, will not change. If the plane  $\pi$  is kept fixed in space the point J will remain fixed, and S describes a circle about J as centre and with SJ as radius. This proves the last part of the theorem, in § 5.

§ 8. The plane  $\pi'$  may be turned either in the sense indicated by the arrow at Z or in the opposite sense till  $\pi'$  falls into  $\pi$ . In the first case we get a figure like fig. 3;  $i'$  and  $j'$  will be on the same side of the axis, and on this side will also lie the centre S;

Fig. 2.

their point of intersection  $E$ , will coincide with their corresponding elements. The row  $AB$  has thus three points  $A, B, E$  coincident with their corresponding points, and is therefore identical with it (§ 10). As there are six lines which join two and two of the four points  $A, B, C, D$ , there are six lines such that each point in either coincides with its corresponding point. Every other line will thus have the six points in which it cuts these, and therefore all points, coincident with their corresponding points. The proof of the second part is exactly the same. It follows—

§ 14. *If two projective figures which are not identical lie in the same plane, then not more than three points which are not in a line, or three lines which do not pass through a point, can be coincident with their corresponding points or lines.*

If the figures are in perspective position, then they have in common one line, the axis, with all points in it, and one point, the centre, with all lines through it. No other point or line can therefore coincide with its corresponding point or line without the figures becoming identical.

It follows also that—

*The correspondence between two projective planes is completely determined if there are given—either to four points in the one the corresponding four points in the other provided that no three of them lie in a line, or to any four lines the corresponding lines provided that no three of them pass through a point.*

To show this we observe first that two planes  $\pi, \pi'$  may be made projective in such a manner that four given points  $A, B, C, D$  in the one correspond to four given points  $A', B', C', D'$  in the other; for to the lines  $AB, CD$  will correspond the lines  $A'B'$  and  $C'D'$ , and to the intersection  $E$  of the former the point  $E'$  where the latter meet. The correspondence between these rows is therefore determined, as we know three pairs of corresponding points. But this determines a correspondence (by § 12). To prove that in this case and also in the case of § 12 there is but one correspondence possible, let us suppose there were two, or that we could have in the plane  $\pi'$  two figures which are each projective to the figure in  $\pi$  and which have each the points  $A'B'C'D'$  corresponding to the points  $ABCD$  in  $\pi$ . Then these two figures will themselves be projective and have four corresponding points coincident. They are therefore identical by § 13.

**THEOREM.**—*Two projective planes will be in perspective position if one row coincides with its corresponding row. The line containing these rows will be the axis of projection.*

*Proof.*—As in this case every point on  $s$  coincides with its corresponding point, it follows that every row  $a$  meets its corresponding row  $a'$  on  $s$  where corresponding points are united. The two rows  $a, a'$  are therefore perspective (G. § 30), and the lines joining corresponding points will meet in a point  $S$ . If  $r$  be any one of these lines cutting  $a, a'$  in the points  $A$  and  $A'$  and the line  $s$  at  $K$ , then to the line  $AK$  corresponds  $A'K$ , or the ray  $r$  corresponds to itself. The points  $B, B'$  in which  $r$  cuts another pair  $b, b'$  of corresponding rows must therefore be corresponding points. Hence the lines joining corresponding points in  $b$  and  $b'$  also pass through  $S$ . Similarly all lines joining corresponding points in the two planes  $\pi$  and  $\pi'$  meet in  $S$ ; hence the planes are perspective.

The following proposition is proved in a similar way:—

**THEOREM.**—*Two projective planes will be in perspective position if one pencil coincides with its corresponding one. The centre of these pencils will be the centre of perspective.*

In this case the two planes must of course coincide, whilst in the first case this is not necessary.

§ 15. We shall now show that two planes which are projective according to definition § 12 can be brought into perspective position, hence that the new definition is really equivalent to the old. We use the following property:—If two coincident planes  $\pi$  and  $\pi'$  are perspective with  $S$  as centre, then any two corresponding rows are also perspective with  $S$  as centre. This therefore is true for the rows  $j$  and  $j'$  and for  $i$  and  $i'$ , of which  $i$  and  $j$  are the lines at infinity in the two planes. If now the plane  $\pi'$  be made to slide on  $\pi$  so that each line moves parallel to itself, then the point at infinity in each line, and hence the whole line at infinity in  $\pi'$ , remains fixed. So does the point at infinity on  $j$ , which thus remains coincident with its corresponding point on  $j'$ , and therefore the rows  $j$  and  $j'$  remain perspective, that is to say the rays joining corresponding points in them meet at some point  $T$ . Similarly the lines joining corresponding points in  $i$  and  $i'$  will meet in some point  $T'$ . These two points  $T$  and  $T'$  originally coincided with each other and with  $S$ .

Conversely, if two projective planes are placed one on the other, then as soon as the lines  $j$  and  $i'$  are parallel the two points  $T$  and  $T'$  can be found by joining corresponding points in  $j$  and  $j'$ , and also in  $i$  and  $i'$ . If now a point at infinity is called  $A$  as a point in  $\pi$  and  $B'$  as a point in  $\pi'$ , then the point  $A'$  will lie on  $i'$  and  $B$  on  $j$ , so that the line  $AA'$  passes through  $T'$  and  $BB'$  through  $T$ . These two lines are parallel. If then the plane  $\pi'$  be moved parallel to itself till  $T'$  comes to  $T$ , then these two lines will coincide with each other, and with them will coincide the lines  $AB$  and  $A'B'$ . This line and similarly every line through  $T$  will thus now coincide

with its corresponding line. The two planes are therefore according to the last theorem in § 14 in perspective position.

It will be noticed that the plane  $\pi'$  may be placed on  $\pi$  in two different ways, viz., if we have placed  $\pi'$  on  $\pi$  we may take it off and turn it over in space before we bring it back to  $\pi$ , so that what was its upper becomes now its lower face. For each of these positions we get one pair of centres  $T, T'$ , and only one pair, because the above process must give every perspective position. It follows—

*In two projective planes there are in general two and only two pencils in either such that angles in one are equal to their corresponding angles in the other. If one of these pencils is made coincident with its corresponding one, then the planes will be perspective.*

This agrees with the fact that two perspective planes in space can be made coincident by turning one about their axis in two different ways (§ 8).

In the reasoning employed it is essential that the lines  $j$  and  $i'$  are finite. If one lies at infinity, say  $j$ , then  $i$  and  $j$  coincide, hence their corresponding lines  $i'$  and  $j'$  will coincide; that is,  $i'$  also lies at infinity, so that the lines at infinity in the two planes are corresponding lines. If the planes are now made coincident and perspective, then it may happen that the lines at infinity correspond point for point, or can be made to do so by turning the one plane in itself. In this case the line at infinity is the axis, whilst the centre may be a finite point. This gives similar figures (see § 16). In the other case the line at infinity corresponds to itself without being the axis; the lines joining corresponding points therefore all coincide with it, and the centre  $S$  lies on it at infinity. The axis will be some finite line. This gives parallel projection (see § 17). For want of space we do not show how to find in these cases the perspective position, but only remark that in the first case any pair of corresponding points in  $\pi$  and  $\pi'$  may be taken as the points  $T$  and  $T'$ , whilst in the other case there is a pencil of parallels in  $\pi$  such that any one line of these can be made to coincide point for point with its corresponding line in  $\pi'$ , and thus serve as the axis of projection. It will therefore be possible to get the planes in perspective position by first placing any point  $A'$  on its corresponding point  $A$  and then turning  $\pi'$  about this point till lines joining corresponding points are parallel.

§ 16. **SIMILAR FIGURES.**—If the axis is at infinity every line is parallel to its corresponding line. Corresponding angles are therefore equal. The figures are similar, and (§ 10) the ratio of similitude of any two corresponding rows is constant.

If similar figures are in perspective position they are said to be similarly situated, and the centre of projection is called the centre of similitude. To place two similar figures in this position, we observe that their lines at infinity will coincide as soon as both figures are put in the same plane, but the rows on them are not necessarily identical. They are projective, and hence in general not more than two points on one will coincide with their corresponding points in the other (G. § 84). To make them identical it is either sufficient to turn one figure in its plane till three lines in one are parallel to their corresponding lines in the other, or it is necessary before this can be done to turn the one plane over in space. It can be shown that in the former case all lines are, or no line is, parallel to its corresponding line, whilst in the second case there are two directions, at right angles to each other, which have the property that each line in either direction is parallel to its corresponding line. We also see that—

*If in two similar figures three lines, of which no two are parallel, are parallel respectively to their corresponding lines, then every line has this property and the two figures are similarly situated; or*

*Two similar figures are similarly situated as soon as two corresponding triangles are so situated.*

If two similar figures are perspective without being in the same plane, their planes must be parallel as the axis is at infinity. Hence

*Any plane figure is projected from any centre to a parallel plane into a similar figure.*

If two similar figures are similarly situated, then corresponding points may either be on the same or on different sides of the centre. If, besides, the ratio of similitude is unity, then corresponding points will be equidistant from the centre. In the first case therefore the two figures will be identical. In the second case they will be identically equal but not coincident. They can be made to coincide by turning one in its plane through two right angles about the centre of similitude  $S$ . The figures are in involution, as is seen at once, and they are said to be *symmetrical with regard to the point  $S$  as centre*. If the two figures be considered as part of one, then this is said to have a centre. Thus regular polygons of an even number of sides and parallelograms have each a centre, which is a centre of symmetry.

§ 17. **PARALLEL PROJECTION.**—If, instead of the axis, the centre be moved to infinity, all the projecting rays will be parallel, and we get what is called *Parallel Projection*. In this case the line at infinity passes through the centre and therefore corresponds to itself, — but not point for point as in the case of similar figures. To any point  $I$  at infinity corresponds therefore a point  $I'$  also at infinity but different from the first. Hence to parallel lines meeting at  $I$  cor-

The moment of inertia of a plane figure does not change if the figure undergoes a shear in the direction of the axis with regard to which the moment has been taken.

If a figure has an axis of skew-symmetry, then this axis and the conjugate direction are conjugate diameters of the momental ellipse for every point in the axis.

If a figure has an axis of symmetry, then this is an axis of the momental ellipse for every point in it.

The truth of the last propositions follows at once from the fact that the product of inertia for the lines in question vanishes.

It is of interest to notice how a great many propositions of Euclid are only special cases of projection. The theorems Encl. I. 35-41 about parallelograms or triangles on equal bases and between the same parallels are examples of shear, whilst I. 43 gives a case of skew-symmetry, hence of involution. Figures which are identically equal are of course projective, and they are perspective when placed so that they have an axis or a centre of symmetry (comp. Henrici, *Elementary Geometry, Congruent Figures*). In this case again the relation is that of involution. The importance of treating similar figures when in perspective position has long been recognized; we need only mention the well-known proposition about the centres of similitude of circles.

#### APPLICATIONS TO CONICS.

§ 21. THEOREM.—Any conic can be projected into any other conic. This may be done in such a manner that three points on one conic and the tangents at two of them are projected to three arbitrarily selected points and the tangents at two of them on the other.

*Proof.*—If  $u$  and  $u'$  are any two conics, then we have to prove that we can project  $u$  in such a manner that five points on it will be projected to points on  $u'$ . As the projection is determined as soon as the projections of any four points or four lines are selected, we cannot project any five points of  $u$  to any five arbitrarily selected points on  $u'$ . But if  $A, B, C$  be any three points on  $u$ , and if the tangents at  $B$  and  $C$  meet at  $D$ , if further  $A', B', C'$  are any three points on  $u'$ , and if the tangents at  $B'$  and  $C'$  meet at  $D'$ , then the plane of  $u$  may be projected to the plane of  $u'$  in such a manner that the points  $A, B, C, D$  are projected to  $A', B', C', D'$ . This determines the correspondence (§ 14). The conic  $u$  will be projected into a conic, the points  $A, B, C$  and the tangents  $BD$  and  $CD$  to the points  $A', B', C'$  and the lines  $B'D'$  and  $C'D'$ , which are tangents to  $u'$  at  $B'$  and  $C'$ . The projection of  $u$  must therefore (G. § 52) coincide with  $u'$ , because it is a conic which has three points and the tangents at two of them in common with  $u'$ .

Similarly we might have taken three tangents and the points of contact of two of them as corresponding to similar elements on the other.

If the one conic be a circle which cuts the line  $j$ , the projection will cut the line at infinity in two points; hence it will be an hyperbola. Similarly, if the circle touches  $j$ , the projection will be a parabola; and, if the circle has no point in common with  $j$ , the projection will be an ellipse. These curves appear thus as sections of a circular cone, for in case that the two planes of projection are separated the rays projecting the circle form such a cone.

Any conic may be projected into itself.

If we take any point  $S$  in the plane of a conic as centre, the polar of this point as axis of projection, and any two points in which a line through  $S$  cuts the conic as corresponding points, then these will be harmonic conjugates with regard to the centre and the axis. We therefore have involution (§ 11), and every point is projected into its harmonic conjugate with regard to the centre and the axis, hence every point  $A$  on the conic into that point  $A'$  on the conic in which the line  $SA'$  cuts the conic again, as follows from the harmonic properties of pole and polar (G. § 62 sq.).

Two conics which cut the line at infinity in the same two points are similar figures and similarly situated, the centre of similitude being in general some finite point.

To prove this, we take the line at infinity and the asymptotes of one as corresponding to the line at infinity and the asymptotes of the other, and besides a tangent to the first as corresponding to a parallel tangent to the other. The line at infinity will then correspond to itself point for point; hence the figures will be similar and similarly situated.

§ 22. AREAS OF PARABOLIC SEGMENTS.—One parabola may always be considered as a parallel projection of another in such a manner that any two points  $A, B$  on the one correspond to any two points  $A', B'$  on the other; that is, the points  $A, B$  and the point at infinity on the one may be made to correspond respectively to the points  $A', B'$  and the point at infinity on the other, whilst the tangents at  $A$  and at infinity of the one correspond to the tangent at  $B'$  and at infinity of the other. This completely determines the correspondence, and it is parallel projection because the line at infinity corresponds to the line at infinity. Let the tangents at  $A$  and  $B$  meet at  $C$ , and those at  $A', B'$  at  $C'$ ; then  $C, C'$  will correspond, and so will the triangles  $ABC$  and  $A'B'C'$  as well as the parabolic segments cut off by the chords  $AB$  and  $A'B'$ . If  $(AB)$

denotes the area of the segment cut off by the chord  $AB$  we have therefore

$$(AB)/ABC = (A'B')/A'B'C'; \text{ or}$$

The area of a segment of a parabola stands in a constant ratio to the area of the triangle formed by the chord of the segment and the tangents at the end points of the chord.

If then (fig. 8) we join the point  $C$  to the mid-point  $M$  of  $AB$ , then this line  $l$  will be bisected at  $D$  by the parabola (G. § 74), and the tangent at  $D$  will be parallel to  $AB$ . Let this tangent cut  $AC$  in  $E$  and  $CB$  in  $F$ , then by the last theorem

$$\frac{(AB)}{ABC} = \frac{(AD)}{ADE} = \frac{(BD)}{BFD} = m,$$

where  $m$  is some number to be determined. The figure gives

$$(AB) = ABD + (AD) + (BD).$$

Combining both equations, we have

$$ABD = m(ABC - ADE - BFD).$$

But we have also  $ABD = \frac{1}{2} ABC$ , and  $ADE = BFD = \frac{1}{2} ABC$ ; hence

$$\frac{1}{2} ABC = m(1 - \frac{1}{2} - \frac{1}{2}) ABC, \text{ or } m = \frac{3}{2}.$$

The area of a parabolic segment equals two-thirds of the area of the triangle formed by the chord and the tangents at the end points of the chord.

§ 23. ELLIPTIC AREAS.—To consider one ellipse a parallel projection of another we may establish the correspondence as follows. If  $AC, BD$  are any pair of conjugate diameters of the one and  $A'C', B'D'$  any pair of conjugate diameters of the other, then these may be made to correspond to each other, and the correspondence will be completely determined if the parallelogram formed by the tangents at  $A, B, C, D$  is made to correspond to that formed by the tangents at  $A', B', C', D'$  (§§ 17 and 21). As the projection of the first conic has the four points  $A', B', C', D'$  and the tangents at these points in common with the second, the two ellipses are projected one into the other. Their areas will correspond, and so do those of the parallelograms  $ABCD$  and  $A'B'C'D'$ . Hence

The area of an ellipse has a constant ratio to the area of any inscribed parallelogram whose diagonals are conjugate diameters, and also to every circumscribed parallelogram whose sides are parallel to conjugate diameters.

It follows at once that

All parallelograms inscribed in an ellipse whose diagonals are conjugate diameters are equal in area; and

All parallelograms circumscribed about an ellipse whose sides are parallel to conjugate diameters are equal in area.

If  $a, b$  are the length of the semi-axes of the ellipse, then the area of the circumscribed parallelogram will be  $4ab$  and of the inscribed one  $2ab$ .

For the circle of radius  $r$  the inscribed parallelogram becomes the square of area  $2r^2$  and the circle has the area  $\pi r^2$ ; the constant ratio of an ellipse to the inscribed parallelogram has therefore also the value  $\frac{1}{2}\pi$ . Hence

The area of an ellipse equals  $ab\pi$ .

§ 24. PROJECTIVE PROPERTIES.—The properties of the projection of a figure depend partly on the relative position of the planes of the figure and the centre of projection, but principally on the properties of the given figure. Points in a line are projected into points in a line, harmonic points into harmonic points, a conic into a conic; but parallel lines are not projected into parallel lines nor right angles into right angles, neither are the projections of equal segments or angles again equal. There are then some properties which remain unaltered by projection, whilst others change. The former are called projective or descriptive, the latter metrical properties of figures, because the latter all depend on measurement.

To a triangle and its median lines correspond a triangle and three lines which meet in a point, but which as a rule are not median lines.

In this case, if we take the triangle together with the line at infinity, we get as the projection a triangle  $ABC$ , and some other line  $j$  which cuts the sides  $a, b, c$  of the triangle in the points  $A_1, B_1, C_1$ . If we now take on  $BC$  the harmonic conjugate  $A_2$  to  $A_1$  and similarly on  $CA$  and  $AB$  the harmonic conjugates to  $B_1$  and  $C_1$  respectively, then the lines  $AA_2, BB_2, CC_2$  will be the projections of the median lines in the given figure. Hence these lines must meet in a point.

As the triangle and the fourth line we may take any four given lines, because any four lines may be projected into any four given lines (§ 14). This gives a theorem:—

If each vertex of a triangle be joined to that point in the opposite side which is, with regard to the vertices, the harmonic conjugate of the point in which the side is cut by a given line, then the three lines thus obtained meet in a point.

We get thus out of the special theorem about the median lines

Fig. 8.

of a triangle a more general one. But before this could be done we had to add the line at infinity to the lines in the given figure.

In a similar manner a great many theorems relating to metrical properties can be generalized by taking the line at infinity or points at infinity as forming part of the original figure. Conversely special cases relating to measurement are obtained by projecting some line in a figure of known properties to infinity. This is true for all properties relating to parallel lines or to bisection of segments, but not immediately for angles. It is, however, possible to establish for every metrical relation the corresponding projective property. To do this it is necessary to consider imaginary elements. These have originally been introduced into geometry by aid of coordinate geometry, where imaginary quantities constantly occur as roots of equations.

Their introduction into pure geometry is due principally to Poncelet, who by the publication of his great work *Traité des Propriétés Projectives des Figures* became the founder of projective geometry in its widest sense. Monge had considered parallel projection and had already distinguished between permanent and accidental properties of figures, the latter being those which depended merely on the accidental position of one part to another. Thus in projecting two circles which lie in different planes it depends on the accidental position of the centre of projection whether the projections be two conics which do or do not meet. Poncelet introduced the principle of continuity in order to make theorems general and independent of those accidental positions which depend analytically on the fact that the equations used have real or imaginary roots. But the correctness of this principle remained without a proof. Von Staudt has, however, shown how it is possible to introduce imaginary elements by purely geometrical reasoning, and we shall now try to give the reader some idea of his theory.

§ 25. IMAGINARY ELEMENTS.—If a line cuts a curve and if the line be moved, turned for instance about a point in it, it may happen that two of the points of intersection approach each other till they coincide. The line then becomes a tangent. If the line is still further moved in the same manner it separates from the curve and two points of intersection are lost. Thus in considering the relation of a line to a conic we have to distinguish three cases—the line cuts the conic in two points, touches it, or has no point in common with it. This is quite analogous to the fact that a quadratic equation with one unknown quantity has either two, one, or no roots. But in algebra it has long been found convenient to express this differently by saying a quadratic equation has always two roots, but these may be either both real and different, or equal, or they may be imaginary. In geometry a similar mode of expressing the fact above stated is not less convenient.

We say therefore a line has always two points in common with a conic, but these are either distinct, or coincident, or invisible. The word imaginary is generally used instead of invisible; but, as the points have nothing to do with imagination, we prefer the word "invisible" recommended originally by Clifford.

Invisible points occur in pairs of conjugate points, for a line loses always two visible points of intersection with a curve simultaneously. This is analogous to the fact that an algebraical equation with real coefficients has imaginary roots in pairs. Only one real line can be drawn through an invisible point, for two real lines meet in a real or visible point. The real line through an invisible point contains also its conjugate.

Similarly there are invisible lines—tangents, for instance, from a point within a conic—which occur in pairs of conjugates, two conjugates having a real point in common.

The introduction of invisible points would be nothing but a play upon words unless there is a real geometrical property indicated which can be used in geometrical constructions—that it has a definite meaning, for instance, to say that two conics cut a line in the same two invisible points, or that we can draw one conic through three real points and the two invisible ones which another conic has in common with a line that does not actually cut it. We have in fact to give a geometrical definition of invisible points. This is done by aid of the theory of involution (G. § 76 sq.).

An involution of points on a line has (according to G. § 77 (2)) either two or one or no foci. Instead of this we now say it has always two foci which may be distinct, coincident, or invisible. These foci are determined by the involution, but they also determine the involution. If the foci are real this follows from the fact that conjugate points are harmonic conjugates with regard to the foci. That it is also the case for invisible foci will presently appear. If we take this at present for granted we may replace a pair of real, coincident, or invisible points by the involution of which they are the foci.

Now any two pairs of conjugate points determine an involution (G. § 77 (6)).

Hence any point-pair, whether real or invisible, is completely determined by any two pairs of conjugate points of the involution which has the given point-pair as foci and may therefore be replaced by them.

Two pairs of invisible points are thus said to be identical if, and only if, they are the foci of the same involution.

We know (G. § 82) that a conic determines on every line an involution in which conjugate points are conjugate poles with regard to the conic—that is, that either lies on the polar of the other. This holds whether the line cuts the conic or not. Furthermore, in the former case the points common to the line and the conic are the foci of the involution. Hence we now say that this is always the case, and that the invisible points common to a line and a conic are the invisible foci of the involution in question. If then we state the problem of drawing a conic which passes through two points given as the intersection of a conic and a line as that of drawing a conic which determines a given involution on the line, we have it in a form in which it is independent of the accidental circumstance of the intersections being real or invisible. So is the solution of the problem, as we shall now show.

§ 26. We have seen (§ 21) that a conic may always be projected into itself by taking any point  $S$  as centre and its polar  $s$  as axis of projection, corresponding points being those in which a line through  $S$  cuts the conic. If then (fig. 9)  $A, A'$  and  $B, B'$  are pairs of corresponding points so that the lines  $AA'$  and  $BB'$  pass through  $S$ , then the lines  $AB$  and  $A'B'$ , as corresponding lines, will meet at a point  $R$  on the axis, and the lines  $AB'$  and  $A'B$  will meet at another point  $R'$  on the axis. These points  $R, R'$  are conjugate points in the involution which the conic determines on the line  $s$ , because the triangle  $RSR'$  is a polar triangle (G. § 62), so that  $R'$  lies on the polar of  $R$ .

Fig. 9.

This gives a simple means of determining for any point  $Q$  on the line  $s$  its conjugate point  $Q'$ . We take any two points  $A, A'$  on the conic which lie on a line through  $S$ , join  $Q$  to  $A$  by a line cutting the conic again in  $C$ , and join  $C$  to  $A'$ . This line will cut  $s$  in the point  $Q'$  required.

PROBLEM.—To draw some conic which shall determine on a line  $s$  a given involution.

Solution.—We have here to reconstruct the fig. 9, having given on the line  $s$  an involution. Let  $Q, Q'$  and  $R, R'$  (fig. 9) be two pairs of conjugate points in this involution. We take any point  $B$  and join it to  $R$  and  $R'$ , and another point  $C$  to  $Q$  and  $Q'$ . Let  $BR$  and  $CQ$  meet at  $A$ , and  $BR'$  and  $CQ'$  at  $A'$ . If now a point  $P$  be moved along  $s$  its conjugate point  $P'$  will also move and the two points will describe projective rows. The two rays  $AP$  and  $A'P'$  will therefore describe projective pencils, and the intersection of corresponding rays will lie on a conic which passes through  $A, A', B$ , and  $C$ . This conic determines on  $s$  the given involution.

Of these four points not only  $B$  and  $C$  but also the point  $A$  may be taken arbitrarily, for if  $A, B, C$  are given, the line  $AB$  will cut  $s$  in some point  $R$ . As the involution is supposed known, we can find the point  $R'$  conjugate to  $R$ , which we join to  $B$ . In the same way the line  $CA$  will cut  $s$  in some point  $Q$ . Its conjugate point  $Q'$  we join to  $C$ . The line  $CQ'$  will cut  $BR'$  in a point  $A'$ , and then  $AA'$  will pass through the pole  $S$  (comp. fig. 9). We may now interchange  $A$  and  $B$  and find the point  $B'$ . Then  $BB'$  will also pass through  $S$ , which is thus found. At the same time five points  $A, B, C, A', B'$  on the conic have been found, so that the conic is completely known which determines on the line  $s$  the given involution. Hence—

THEOREM.—Through three points we can always draw one conic, and only one, which determines on a given line a given involution, all the same whether the involution has real, coincident, or invisible foci.

In the last case the theorem may now also be stated thus:—  
THEOREM.—It is always possible to draw a conic which passes through three given real points and through two invisible points which any other conic has in common with a line.

§ 27. The above theory of invisible points gives rise to a great number of interesting consequences of which we state a few.

The theorem at the end of § 21 may now be stated:—

THEOREM.—Any two conics are similar and similarly situated if they cut the line at infinity in the same two points—real, coincident, or invisible.

It follows that  
Any two parabolas are similar; and they are similarly situated as soon as their axes are parallel.

The involution which a circle determines at its centre is circular (G. § 79); that is, every line is perpendicular to its conjugate line. This will be cut by the line at infinity in an involution which has the following property:—The lines which join any finite point to two conjugate points in the involution are at right angles to each other. Hence all circular involutions in a plane determine the

same involution on the line at infinity. The latter is therefore called the *circular involution on the line at infinity*; and the involution which a circle determines at its centre is called the *circular involution at that point*. All circles determine thus on the line at infinity the same involution; in other words, they have the same two invisible points in common with the line at infinity.

**THEOREM.**—All circles may be considered as passing through the same two points at infinity.

These points are called the *circular points at infinity*, and by Prof. Cayley the *absolute* in the plane. They are the foci of the circular involution in the line at infinity.

Conversely—Every conic which passes through the circular points is a circle; because the involution at its centre is circular, hence conjugate diameters are at right angles, and this property only circles possess.

We now see why we can draw always one and only one circle through any three points: these three points together with the circular points at infinity are five points through which one conic only can be drawn.

Any two circles are similar and similarly situated because they have the same points at infinity (§ 21).

Any two concentric circles may be considered as having double contact at infinity, because the lines joining the common centre to the circular points at infinity are tangents to both circles at the circular points, as the line at infinity is the polar of the centre.

Any two lines at right angles to one another are harmonic conjugates with regard to the rays joining their intersection to the circular points, because these rays are the focal rays of the circular involution at the intersection of the given lines.

To bisect an angle with the vertex  $A$  means (G. § 23) to find two rays through  $A$  which are harmonic conjugates with regard to the limits of the angle and perpendicular to each other. These rays are therefore harmonic with regard to the limits of the given angle and with regard to the rays through the circular points. Thus perpendicularity and bisection of an angle have been stated in a projective form.

It must not be forgotten that the circular points do not exist at all; but to introduce them gives us a short way of making a statement which would otherwise be long and cumbersome.

We can now generalize any theorem relating to metrical properties. For instance, the simple fact that the chord of a circle is touched by a concentric circle at its mid point proves the theorem:

If two conics have double contact, then the points where any tangent to one of them cuts the other are harmonic with regard to the point of contact and the point where the tangent cuts the chord of contact.

## DESCRIPTIVE GEOMETRY.

For many, especially technical, purposes it is of the utmost importance to represent solids and other figures in three dimensions by a drawing in one plane.

A variety of methods have been introduced for this purpose. The most important is that which towards the end of the last century was invented by Monge under the name of "descriptive geometry." We give the elements of his method. It is based on parallel projections to a plane by rays perpendicular to the plane. Such a projection is called *orthographic* (§ 18). If the plane is horizontal the projection is called the *plan* of the figure, and if the plane is vertical the *elevation*. In Monge's method a figure is represented by its plan and elevation. It is therefore often called *drawing in plan and elevation*, and sometimes simply *orthographic projection*.

§ 23. We suppose then that we have two planes, one horizontal, the other vertical, and these we call the planes of plan and of elevation respectively, or the horizontal and the vertical plane, and denote them by the letters  $\pi_1$  and  $\pi_2$ . Their line of intersection is called the axis, and shall be denoted by the letter  $x$ .

If the surface of the drawing paper is taken as the plane of the plan, then the vertical plane will be the plane perpendicular to it through the axis  $x$ . To bring this also into the plane of the drawing paper we turn it about the axis till it coincides with the horizontal plane. This process of turning one plane down till it coincides with another is called *rabatting* one to the other. Of course there is no necessity to have one of the two planes horizontal, but even when this is not the case it is convenient to retain the above names.

The whole arrangement will be better understood by a glance at fig. 10. A point  $A$  in space is there projected by the perpendicular  $AA_1$  and  $AA_2$  to the planes  $\pi_1$  and  $\pi_2$ , so that  $A_1$  and  $A_2$  are the horizontal and vertical projections of  $A$ .

If we remember that a line is perpendicular to a plane that

is perpendicular to every line in the plane if only it is perpendicular to any two intersecting lines in the plane,<sup>1</sup> we see that the axis which is perpendicular both to  $AA_1$  and to  $AA_2$  is also perpendicular to  $A_1A_2$  and to  $A_2A_1$  because these four lines are all in the same plane. Hence, if the plane  $\pi_2$  be turned about the

Fig. 10.

Fig. 11.

axis till it coincides with the plane  $\pi_1$ , then  $A_2A_1$  will be the continuation of  $A_1A_3$ . This position of the planes is represented in fig. 11, in which the line  $A_1A_2$  is perpendicular to the axis  $x$ .

Conversely any two points  $A_1, A_2$  in a line perpendicular to the axis will be the projections of some point in space when the plane  $\pi_2$  is turned about the axis till it is perpendicular to the plane  $\pi_1$ , because in this position the two perpendiculars to the planes  $\pi_1$  and  $\pi_2$  through the points  $A_1$  and  $A_2$  will be in a plane and therefore meet at some point  $A$ .

**REPRESENTATION OF POINTS.**—We have thus the following method of representing in a single plane the position of points in space:—we take in the plane a line  $x$  as the axis, and then any pair of points  $A_1, A_2$  in the plane on a line perpendicular to the axis represent a point  $A$  in space. If the line  $A_1A_2$  cuts the axis at  $A_0$ , and if at  $A_1$  a perpendicular be erected to the plane, then the point  $A$  will be in it at a height  $A_1A = A_0A_2$  above the plane. This gives the position of the point  $A$  relative to the plane  $\pi_1$ . In the same way, if in a perpendicular to  $\pi_2$  through  $A_2$  a point  $A$  be taken such that  $A_2A = A_0A_1$ , then this will give the point  $A$  relative to the plane  $\pi_2$ .

§ 29. The two planes  $\pi_1, \pi_2$  in their original position divide space into four parts. These are called the four quadrants. We suppose that the plane  $\pi_2$  is turned as indicated in fig. 10, so that the point  $P$  comes to  $Q$  and  $R$  to  $S$ , then the quadrant in which the point  $A$  lies is called the first, and we say that in the first quadrant a point lies above the horizontal and in front of the vertical plane. Now we go round the axis in the sense in which the plane  $\pi_2$  is turned and come in succession to the second, third, and fourth quadrant. In the second a point lies above the plane of the plan and behind the plane of elevation, and so on. In fig. 12, which represents a side view of the planes in fig. 10, the quadrants are marked, and in each a point with its projection is taken. Fig. 11 shows how these are represented when the plane  $\pi_2$  is turned down. We see that

A point lies in the first quadrant if the plan lies below, the elevation above the axis; in the second if plan and elevation both lie above; in the third if the plan lies above, the elevation below; in the fourth if plan and elevation both lie below the axis.

If a point lies in the horizontal plane, its elevation lies in the axis and the plan coincides with the point itself. If a point lies in the vertical plane, its plan lies in the axis and the elevation coincides with the point itself. If a point lies in the axis, both its plan and elevation lie in the axis and coincide with it.

Of each of these propositions, which will easily be seen to be true, the converse holds also.

§ 30. **REPRESENTATION OF A PLANE.**—As we are thus enabled to represent points in a plane, we can represent any finite figure by representing its separate points. It is, however, not possible to represent a plane in this way, for the projections of its points completely cover the planes  $\pi_1$  and  $\pi_2$ , and no plane would appear different from any other. But any plane  $\alpha$  cuts each of the planes  $\pi_1, \pi_2$  in a line. These are called the traces of the plane. They cut each other in the axis at the point where the latter cuts the plane  $\alpha$ .

A plane is determined by its two traces, which are two lines that meet on the axis, and, conversely, any two lines which meet on the axis determine a plane.

<sup>1</sup> It is very convenient here to make use of the modern extension of the meaning of an angle according to which we take as the angle between two non-intersecting lines the angle between two intersecting lines parallel respectively to the given ones. If this angle is a right angle, the lines are called perpendiculars. Euclid's definition (XI. def. 3), and theorem (XI. 4) may then be stated as in the text. Compare also ARITHMETIC (EUCLIDIAN), § 76, vol. x. p. 386.

Fig. 12.

If the plane is parallel to the axis its traces are parallel to the axis. Of these one may be at infinity; then the plane will cut one of the planes of projection at infinity and will be parallel to it. Thus a plane parallel to the horizontal plane of the plan has only one finite trace, viz., that with the plane of elevation.

If the plane passes through the axis both its traces coincide with the axis. This is the only case in which the representation of the plane by its two traces fails. A third plane of projection is therefore introduced, which is best taken perpendicular to the other two. We call it simply the third plane, and denote it by  $\pi_3$ . As it is perpendicular to  $\pi_1$ , it may be taken as the plane of elevation, its line of intersection  $y$  with  $\pi_1$  being the axis, and be turned down to coincide with  $\pi_1$ . This is represented in fig. 13. OC is the axis  $x$  whilst OA and OB are the traces of the third plane. They lie in one line  $y$ . The plane is rabatted about  $y$  to the horizontal plane. A plane  $\alpha$  through the axis  $x$  will then show in it a trace  $\alpha_3$ . In fig. 13 the lines OC and OP will thus be the traces of a plane through the axis  $x$  which makes an angle POQ with the horizontal plane.

We can also find the trace which any other plane makes with  $\pi_3$ . In rabutting the plane  $\pi_3$  its trace OB with the plane  $\pi_2$  will come to the position OD. Hence a plane  $\beta$  having the traces CA and CB will have with the third plane the trace  $\beta_3$ , or AD if OD=OB.

It also follows immediately that—

If a plane  $\alpha$  is perpendicular to the horizontal plane, then every point in it has its horizontal projection in the horizontal trace of the plane, as all the rays projecting these points lie in the plane itself.

Any plane which is perpendicular to the horizontal plane has its vertical trace perpendicular to the axis.

Any plane which is perpendicular to the vertical plane has its horizontal trace perpendicular to the axis and the vertical projections of all points in the plane lie in this trace.

§ 31. REPRESENTATION OF A LINE.—A line is determined either by two points in it or by two planes through it. We get accordingly two representations of it either by projections or by traces.

First.—A line  $a$  is represented by its projections  $a_1$  and  $a_2$  on the two planes  $\pi_1$  and  $\pi_2$ . These may be any two lines, for, bringing the planes  $\pi_1$ ,  $\pi_2$  into their original position, the planes through these lines perpendicular to  $\pi_1$  and  $\pi_2$  respectively will intersect in some line  $a$  which has  $a_1$ ,  $a_2$  as its projections.

Secondly.—A line  $a$  is represented by its traces—that is, by the points in which it cuts the two planes  $\pi_1$ ,  $\pi_2$ . Any two points may be taken as the traces of a line in space, for it is determined when the planes are in their original position as the line joining the two traces. This representation becomes undetermined if the two traces coincide in the axis. In this case we again use a third plane, or else the projections of the line.

§ 32. The fact that there are different methods of representing points and planes, and hence two methods of representing lines, suggests the principle of duality (G. § 41). It is worth while to keep this in mind. It is also worth remembering that traces of planes or lines always lie in the planes or lines which they represent. Projections do not as a rule do this excepting when the point or line projected lies in one of the planes of projection.

§ 33. Having now shown how to represent points, planes, and lines, we have to state the conditions which must hold in order that these elements may lie one in the other, or else that the figure formed by them may possess certain metrical properties. It will be found that the former are very much simpler than the latter.

Before we do this, however, we shall explain the notation used; for it is of great importance to have a systematic notation. We shall denote points in space by capitals A, B, C; planes in space by Greek letters  $\alpha$ ,  $\beta$ ,  $\gamma$ ; lines in space by small letters  $a$ ,  $b$ ,  $c$ ; horizontal projections by suffixes 1, like  $A_1$ ,  $a_1$ ; vertical projections by suffixes 2, like  $A_2$ ,  $a_2$ ; traces by single and double dashes  $a'$ ,  $a''$ ,  $a'$ ,  $a''$ . Hence  $P_1$  will be the horizontal projection of a point P in space; a line  $a$  will have the projections  $a_1$ ,  $a_2$  and the traces  $a'$  and  $a''$ ; a plane  $\alpha$  has the traces  $\alpha'$  and  $\alpha''$ .

§ 34. If a point lies in a line, the projections of the point lie in the projections of the line.

If a line lies in a plane, the traces of the line lie in the traces of the plane.

These propositions follow at once from the definitions of the projections and of the traces.

If a point lies in two lines its projections must lie in the projections of both. Hence

If two lines, given by their projections, intersect, the intersection of their plans and the intersection of their elevations must lie in a line perpendicular to the axis, because they must be the projections of the point common to the two lines.

Similarly.—If two lines given by their traces lie in the same plane or intersect, then the lines joining their horizontal and vertical traces respectively must meet on the axis, because they must be the traces of the plane through them.

§ 35. To find the projections of a line which joins two points A, B given by their projections  $A_1$ ,  $A_2$  and  $B_1$ ,  $B_2$ , we join  $A_1$ ,  $B_1$  and  $A_2$ ,  $B_2$ ; these will be the projections required. For example, the traces of a line are two points in the line whose projections are known or at all events easily found. They are the traces themselves and the feet of the perpendiculars from them to the axis.

Hence if  $a'$ ,  $a''$  (fig. 14) are the traces of a line  $a$ , and if the perpendiculars from them cut the axis in P and Q respectively, then the line  $a'Q$  will be the horizontal and  $a''P$  the vertical projection of the line.

Conversely, if the projections  $a_1$ ,  $a_2$  of a line are given, and if these cut the axis in Q and P respectively, then the perpendiculars  $Pa'$  and  $Qa''$  to the axis drawn through these points cut the projections  $a_1$  and  $a_2$  in the traces  $a'$  and  $a''$ .

To find the line of intersection of two planes, we observe that this line lies in both planes; its traces must therefore lie in the traces of both. Hence the points where the horizontal traces of the given planes meet will be the horizontal, and the point where the vertical traces meet the vertical trace of the line required.

§ 36. To decide whether a point A, given by its projections, lies in a plane  $\alpha$ , given by its traces, we draw a line  $p$  by joining A to some point in the plane  $\alpha$  and determine its traces. If these lie in the traces of the plane, then the line, and therefore the point A, lies in the plane; otherwise not. This is conveniently done by joining A to some point  $p'$  in the trace  $\alpha'$ ; this gives  $p_1$ ; and the point where the perpendicular from  $p'$  to the axis cuts the latter we join to  $A_2$ ; this gives  $p_2$ . If the vertical trace of this line lies in the vertical trace of the plane, then, and then only, does the line  $p$ , and with it the point A, lie in the plane  $\alpha$ .

§ 37. Parallel planes have parallel traces, because parallel planes are cut by any plane, hence also by  $\pi_1$ , and by  $\pi_2$ , in parallel lines.

Parallel lines have parallel projections, because points at infinity are projected to infinity.

If a line is parallel to a plane, then lines through the traces of the line and parallel to the traces of the plane must meet on the axis, because these lines are the traces of a plane parallel to the given plane.

§ 38. To draw a plane through two intersecting lines or through two parallel lines, we determine the traces of the lines; the lines joining their horizontal and vertical traces respectively will be the horizontal and vertical traces of the plane. They will meet, at a finite point or at infinity, on the axis if the lines do intersect.

To draw a plane through a line and a point without the line, we join the given point to any point in the line and determine the plane through this and the given line.

To draw a plane through three points which are not in a line, we draw two of the lines which each join two of the given points and draw the plane through them. If the traces of all three lines AB, BC, CA be found, these must lie in two lines which meet on the axis.

§ 39. We have in the last example got more points, or can easily get more points, than are necessary for the determination of the figure required—in this case the traces of the plane. This will happen in a great many constructions and is of considerable importance. It may happen that some of the points or lines obtained are not convenient in the actual construction. The horizontal traces of the lines AB and AC may, for instance, fall very near together, in which case the line joining them is not well defined. Or, one or both of them may fall beyond the drawing paper, so that they are practically non-existent for the construction. In this case the traces of the line BC may be used. Or, if the vertical traces of AB and AC are both in convenient position, so that the vertical trace of the required plane is found and one of the horizontal traces is got, then we may join the latter to the point where the vertical trace cuts the axis.

Furthermore the draughtsman will never forget that the lines which he draws are not mathematical lines without thickness. For this reason alone every drawing is affected by some errors. And inaccuracies also come in in drawing the lines required in the construction. It is therefore very desirable to be able constantly to check the latter. Such checks always present themselves when the same result can be obtained by different constructions, or

when, as in the above case, some lines must meet on the axis, or if three points must lie in a line. A careful draughtsman will always avail himself of these checks.

§ 40. To draw a plane through a given point parallel to a given plane  $\alpha$ , we draw through the point two lines which are parallel to the plane  $\alpha$ , and determine the plane through them; or, as we know that the traces of the required plane are parallel to those of the given one (§ 37), we need only draw one line  $l$  through the point parallel to the plane and find one of its traces, say the vertical trace  $l'$ ; a line through this parallel to the vertical trace of  $\alpha$  will be the vertical trace  $\beta'$  of the required plane  $\beta$ , and a line parallel to the horizontal trace of  $\alpha$  meeting  $\beta'$  on the axis will be the horizontal trace  $\beta''$ .

Let  $A_1, A_2$  (fig. 15) be the given point,  $\alpha'$  the given plane, a line  $l_1$  through  $A_1$  parallel to  $\alpha'$  and a horizontal line  $l_2$  through  $A_2$  will be the projections of a line  $l$  through  $A$  parallel to the plane, because the horizontal plane through this line will cut the plane  $\alpha$  in a line  $c$  which has its horizontal projection  $c_1$  parallel to  $\alpha'$ .

§ 41. We now come to the metrical properties of figures.

A line is perpendicular to a plane if the projections of the line are perpendicular to the traces of the plane. We prove it for the horizontal projection. If a line  $p$  is perpendicular to a plane  $\alpha$ , every plane through  $p$  is perpendicular to  $\alpha$ ; hence also the vertical plane which projects the line  $p$  to  $p_1$ . As this plane is perpendicular both to the horizontal plane and to the plane  $\alpha$ , it is also perpendicular to their intersection—that is, to the horizontal trace of  $\alpha$ . It follows that every line in this projecting plane, therefore also  $p_1$ , the plan of  $p$ , is perpendicular to the horizontal trace of  $\alpha$ . Q.E.D.

To draw a plane through a given point  $A$  perpendicular to a given line  $p$ , we first draw through some point  $O$  in the axis lines  $\gamma', \gamma''$  perpendicular respectively to the projections  $p_1, p_2$  of the given line. These will be the traces of a plane  $\gamma$  which is perpendicular to the given line. We next draw through the given point  $A$  a plane parallel to the plane  $\gamma$ ; this will be the plane required.

Other metrical properties depend on the determination of the real size or shape of a figure.

In general the projection of a figure differs both in size and shape from the figure itself. But figures in a plane parallel to a plane of projection will be identical with their projections, and will thus be given in their true dimensions. In other cases there is the problem, constantly recurring, either to find the true shape and size of a plane figure when plan and elevation are given, or, conversely, to find the latter from the known true shape of the figure itself. To do this, the plane is turned about one of its traces till it is laid down into that plane of projection to which the trace belongs. This is technically called *rabatting* the plane respectively into the plane of the plan or the elevation. As there is no difference in the treatment of the two cases, we shall consider only the case of rabatting a plane  $\alpha$  into the plane of the plan. The plan of the figure is a parallel (orthographic) projection of the figure itself. The results of parallel projection (§§ 17 and 18) may therefore now be used. The trace  $\alpha'$  will hereby take the place of what formerly was called the axis of projection. Hence we see that corresponding points in the plan and in the rabatted plane are joined by lines which are perpendicular to the trace  $\alpha'$  and that corresponding lines meet on this trace. We also see that the correspondence is completely determined if we know for one point or one line in the plan the corresponding point or line in the rabatted plane.

Before, however, we treat of this we consider some special cases.

§ 42. To determine the distance between two points  $A, B$  given by their projections  $A_1, B_1$  and  $A_2, B_2$ .

Solution.—The two points  $A, B$  in space lie vertically above their plans  $A_1, B_1$  (fig. 16) and  $A_2, B_2$ . The four points  $A, B, A_1, B_1$  therefore form a plane quadrilateral on the base  $A_1B_1$  and having right angles at the base. This plane we rabatt about  $A_1B_1$  by drawing  $A_1A$  and  $B_1B$  perpendicular to  $A_1B_1$  and making  $A_1A = A_0A_2, B_1B = B_0B_2$ . Then  $AB$  will give the length required.

The construction might have been performed in the elevation by

Fig. 15.

making  $A_1A = A_0A_2$  and  $B_1B = B_0B_2$ , on lines perpendicular to  $A_1B_1$ . Of course  $AB$  must have the same length in both cases.

This figure may be turned into a model. We cut the paper along  $A_1A, AB$ , and  $BB_1$  and fold the piece  $A_1ABB_1$  over along  $A_1B_1$  till it stands upright at right angles to the horizontal plane. The points  $A, B$  will then be in their true position in space relative to  $\pi_1$ . Similarly if  $B_2BAA_2$  be cut out and turned along  $A_2B_2$  through a right angle we shall get  $AB$  in its true position relative to the plane  $\pi_2$ . Lastly we fold the whole plane of the paper along the axis  $x$  till the plane  $\pi_2$  is at right angles to  $\pi_1$ . In this position the two sets of points  $AB$  will coincide in the drawing has been accurate.

Models of this kind can be made in many cases and their construction cannot be too highly recommended in order to realize orthographic projection.<sup>1</sup>

§ 43. To find the angle between two given lines  $a, b$  of which the projections  $a_1, b_1$  and  $a_2, b_2$  are given.

Solution.—Let  $a_1, b_1$  (fig. 17) meet in  $P_1, a_2, b_2$  in  $T$ , then if the line  $P_1T$  is not perpendicular to the axis the two lines will not meet. In this case we draw a line parallel to  $b$  to meet the line  $a$ . This is easiest done by drawing first the line  $P_1P_2$  perpendicular to the axis to meet  $a_2$  in  $P_2$ , and then drawing through  $P_2$  a line  $c_2$  parallel to  $b_2$ ; then  $b_1, c_2$  will be the projections of a line  $c$  which is parallel to  $b$  and meets  $a$  in  $P$ . The plane  $\alpha$  which these two lines determine we rabatt to the plan. We determine the traces  $\alpha'$

Fig. 17.

and  $\alpha''$  of the lines  $a$  and  $c$ ; then  $\alpha'\alpha''$  is the trace  $\alpha'$  of their plane. On rabatting the point  $P$  comes to a point  $S$  on the line  $P_1Q$  perpendicular to  $\alpha'$ , so that  $QS = QP$ . But  $QP$  is the hypotenuse of a triangle  $PP_1Q$  with a right angle  $P_1$ . This we construct by making  $QR = P_0P_2$ ; then  $P_1R = PQ$ . The lines  $\alpha'S$  and  $c'S$  will therefore include angles equal to those made by the given lines. It is to be remembered that two lines include two angles which are supplementary. Which of these is to be taken in any special case depends upon the circumstances.

To determine the angle between a line and a plane, we draw through any point in the line a perpendicular to the plane (§ 41) and determine the angle between it and the given line. The complement of this angle is the required one.

To determine the angle between two planes, we draw through any point two lines perpendicular to the two planes and determine the angle between the latter as above.

In special cases it is simpler to determine at once the angle between the two planes by taking a plane section perpendicular to the intersection of the two planes and rabatt this. This is especially the case if one of the planes is the horizontal or vertical plane of projection.

Thus in fig. 18 the angle  $P_1QR$  is the angle which the plane  $\alpha$  makes with the horizontal plane.

§ 44. We return to the general case of rabatting a plane  $\alpha$  of which the traces  $\alpha', \alpha''$  are given.

Here it will be convenient to determine first the position which the trace  $\alpha''$ —which is a line in  $\alpha$ —assumes when rabatted. Points in this line coincide with their elevations. Hence it is given in its true dimension, and we can measure off along it the true distance between two points in it. If therefore (fig. 18)  $P$  is any point in  $\alpha''$  originally coincident with its elevation  $P_2$ , and if  $O$  is the point where  $\alpha''$  cuts the axis  $x$ , so that  $O$  is also in  $\alpha'$ , then the point  $P$  will after rabatting the plane assume such a position that  $OP = OP_2$ . At the same time the plan is an orthographic projection of the plane  $\alpha$ . Hence the line joining  $P$  to the plan  $P_1$  will after rabatting be perpendicular to  $\alpha'$ . But  $P_1$  is known; it is the foot of the perpendicular from  $P_2$  to the axis  $x$ . We draw therefore, to find  $P$ , from  $P_1$  a perpendicular  $P_1Q$  to  $\alpha'$  and find on it a point  $P$  such that  $OP = OP_2$ .

Fig. 18.

<sup>1</sup> In order to make a sharp crease along  $A_1B_1$ , it is well to place a straight edge along this line, and then to turn the piece  $A_1ABB_1$  up against it.

Then the line  $OP$  will be the position of  $a''$  when rabatted. This line corresponds therefore to the plan of  $a''$ —that is, to the axis  $x$ , corresponding points on these lines being those which lie on a perpendicular to  $a'$ .

We have thus one pair of corresponding lines and can now find for any point  $B_1$  in the plan the corresponding point  $B$  in the rabatted plane. We draw a line through  $B_1$ , say  $B_1P_1$ , cutting  $a'$  in  $C$ . To it corresponds the line  $CP$ , and the point where this is cut by the projecting ray through  $B_1$ , perpendicular to  $a'$ , is the required point  $B$ .

Similarly any figure in the rabatted plane can be found when the plan is known; but this is usually found in a different manner without any reference to the general theory of parallel projection. As this method and the reasoning employed for it have their peculiar advantages, we give it also.

Supposing the planes  $\pi_1$  and  $\pi_2$  to be in their positions in space perpendicular to each other, we take a section of the whole figure by a plane perpendicular to the trace  $a'$  about which we are going to rabatt the plane  $a$ . Let this section pass through the point  $Q$  in  $a'$ . Its traces will then be the lines  $QP_1$  and  $P_1P_2$  (fig. 18). These will be at right angles, and will therefore, together with the section  $QP_2$  of the plane  $a$ , form a right-angled triangle  $QP_1P_2$  with the right angle at  $P_1$ , and having the sides  $P_1Q$  and  $P_1P_2$  which both are given in their true lengths. This triangle we rabatt about its base  $P_1Q$ , making  $P_1R = P_1P_2$ . The line  $QR$  will then give the true length of the line  $QP$  in space. If now the plane  $a$  be turned about  $a'$  the point  $P$  will describe a circle about  $Q$  as centre with radius  $QP = QR$ , in a plane perpendicular to the trace  $a'$ . Hence when the plane  $a$  has been rabatted into the horizontal plane the point  $P$  will lie in the perpendicular  $P_1Q$  to  $a'$ , so that  $QP = QR$ .

If  $A_1$  is the plan of a point  $A$  in the plane  $a$ , and if  $A_1$  lies in  $QP_1$ , then the point  $A$  will lie vertically above  $A_1$  in the line  $QP$ . On turning down the triangle  $QP_1P_2$ , the point  $A$  will come to  $A_0$ , the line  $A_1A_0$  being perpendicular to  $QP_1$ . Hence  $A$  will be a point in  $QP$  such that  $QA = QA_0$ .

If  $B_1$  is the plan of another point, but such that  $A_1B_1$  is parallel to  $a'$ , then the corresponding line  $AB$  will also be parallel to  $a'$ . Hence, if through  $A$  a line  $AB$  be drawn parallel to  $a'$ , and  $B_1B$  perpendicular to  $a'$ , then their intersection gives the point  $B$ . Thus of any point given in plan the real position in the plane  $a$ , when rabatted, can be found by this second method. This is the one most generally given in books on geometrical drawing. The first method explained is, however, in most cases preferable as it gives the draughtsman a greater variety of constructions. It requires a somewhat greater amount of theoretical knowledge.

If instead of our knowing the plan of a figure the latter is itself given; then the process of finding the plan is the reverse of the above and needs little explanation. We give an example.

§ 45. PROBLEM.—It is required to draw the plan and elevation of a polygon of which the real shape and position in a given plane  $a$  are known.

Solution.—We first rabatt the plane  $a$  (fig. 19) as before so that  $P_1$  comes to  $P$ , hence

Fig. 19.

$OP_1$  to  $OP$ . Let the given polygon in  $a$  be the figure  $ABCDE$ . We project, not the vertices, but the sides. To project the line  $AB$ , we produce it to cut  $a'$  in  $F$  and  $OP$  in  $G$ , and draw  $GG_1$  perpendicular to  $a'$ ; then

$G_1$  corresponds to  $G$ , therefore  $FG_1$  to  $FG$ . In the same manner we might project all the other sides, at least those which cut  $OP$  and  $OP$  in convenient points. It will be best, however, first to produce all the sides to cut  $OP$  and  $a'$  and then to draw all the projecting rays through  $A, B, C, \dots$  perpendicular to  $a'$ , and in the same direc-

tion the lines  $G, G_1$ , &c. By drawing  $FG$  we get the points  $A_1, B_1$  on the projecting ray through  $A$  and  $B$ . We then join  $B$  to the point  $M$  where  $BC$  produced meets the trace  $a'$ . This gives  $C_1$ . So we go on till we have found  $E_1$ . The line  $A_1E_1$  must then meet  $AE$  in  $a'$ , and this gives a check. If one of the sides cuts  $a'$  or  $OP$  beyond the drawing paper this method fails, but then we may easily find the projection of some other line, say of a diagonal, or directly the projection of a point, by the former methods. The diagonals may also serve to check the drawing, for two corresponding diagonals must meet in the trace  $a'$ .

Having got the plan we easily find the elevation. The elevation of  $G$  is above  $G_1$  in  $a''$ , and that of  $F$  is at  $F_2$  in the axis. This gives the elevation  $F_2G_2$  of  $FG$  and in it we get  $A_2B_2$  in the verticals through  $A_1$  and  $B_1$ . As a check we have  $OG = OG_2$ . Similarly the elevation of the other sides and vertices are found.

§ 46. We have now obtained the  $ABC$  of descriptive geometry, and proceed to give some applications to the representation of solids and of the solution of problems connected with them.

PROBLEM.—Of a pyramid are given its base, the length of the perpendicular from the vertex to the base, and the point where this perpendicular cuts the base; it is required first to develop the whole surface of the pyramid into one plane, and second to determine its section by a plane which cuts the plane of the base in a given line and makes a given angle with it.

Solution.—(1) As the planes of projection are not given we can take them as we like, and we select them in such a manner that the solution becomes as simple as possible. We take the plane of the base as the horizontal plane and the vertical plane perpendicular to the plane of the section. Let then (fig. 20)  $ABCD$  be the base of the pyramid,  $V_1$  the plan of the vertex, then the elevations of  $A, B, C, D$  will be in the axis at  $A_2, B_2, C_2, D_2$ , and the vertex at some point  $V_2$  above  $V_1$  at a known distance

Fig. 20.

from the axis. The lines  $V_1A, V_1B$ , &c., will be the plans and the lines  $V_2A_2, V_2B_2$ , &c., the elevations of the edges of the pyramid, of which thus plan and elevation are known.

We develop the surface into the plane of the base by turning each lateral face about its lower edge into the horizontal plane by the method used in § 43. If one face has been turned down, say  $ABV$  to  $ABP$ , then the point  $Q$  to which the vertex of the next face  $BCV$  comes can be got more simply by finding on the line  $V_1Q$  perpendicular to  $BC$  the point  $Q$  such that  $BQ = BP$ , for these lines represent the same edge  $BV$  of the pyramid. Next  $R$  is found by making  $CR = CQ$ , and so on till we have got the last vertex—in this case  $S$ . The fact that  $AS$  must equal  $AP$  gives a convenient check.

(2) The plane  $a$  whose section we have to determine has its horizontal trace given perpendicular to the axis, and its vertical trace makes the given angle with the axis. This determines it. To find the section of the pyramid by this plane there are two methods applicable: we find the sections of the plane either with the faces or with the edges of the pyramid. We use the latter.

As the plane  $a$  is perpendicular to the vertical plane, the trace  $a'$  contains the projection of every figure in it: the points  $E_2, F_2, G_2, H_2$  where this trace cuts the elevations of the edges will therefore be the elevations of the points where the edges cut  $a$ . From these we find the plans  $E_1, F_1, G_1, H_1$ , and by joining them the

plan of the section. If from  $E_1$ ,  $F_1$  lines be drawn perpendicular to  $AB$ , these will determine the points  $E$ ,  $F$  on the developed face in which the plane  $\alpha$  cuts it; hence also the line  $EF$ . Similarly on the other faces. Of course  $BF$  must be the same length on  $BP$  and on  $BQ$ . If the plane  $\alpha$  be rabatted to the plan, we get the real shape of the section as shown in the figure in  $EFGH$ . This is done easily by making  $F_1F = OF_1$ , &c. If the figure representing the development of the pyramid, or better a copy of it, is cut out, and if the lateral faces be bent along the lines  $AB$ ,  $BC$ , &c., we get a model of the pyramid with the section marked on its faces. This may be placed on its plan  $ABCD$  and the plane of elevation bent about the axis  $z$ . The pyramid stands then in front of its elevations. If next the plane  $\alpha$  with a hole cut out representing the true section be bent along the trace  $\alpha'$  till its edge coincides with  $\alpha''$ , the edges of the hole ought to coincide with the lines  $EF$ ,  $FG$ , &c., on the faces.

§ 47. Polyhedra like the pyramid in § 46 are represented by the projections of their edges and vertices. But solids bounded by curved surfaces, or surfaces themselves, cannot be thus represented.

For a surface we may use, as in case of the plane, its traces—that is, the curves in which it cuts the planes of projection. We may also project points and curves on the surface. A ray cuts the surface generally in more than one point; hence it will happen that some of the rays touch the surface, if two of these points coincide. The points of contact of these rays will form some curve on the surface and this will appear from the centre of projection as the boundary of the surface or of part of the surface. The outlines of all surfaces of solids which we see about us are formed by the points at which rays through our eye touch the surface. The projections of these contours are therefore best adapted to give an idea of the shape of a surface.

Thus the tangents drawn from any finite centre to a sphere form a right circular cone, and this will be cut by any plane in a conic. It is often called the projection of a sphere, but it is better called the contour-line of the sphere, as it is the boundary of the projections of all points on the sphere.

If the centre is at infinity the tangent cone becomes a right circular cylinder touching the sphere along a great circle, and if the projection is, as in our case, orthographic, then the section of this cone by a plane of projection will be a circle equal to the great circle of the sphere. We get such a circle in the plan and another in the elevation, their centres being plan and elevation of the centre of the sphere.

Similarly the rays touching a cone of the second order will lie in two planes which pass through the vertex of the cone, the contour-line of the projection of the cone consists therefore of two lines meeting in the projection of the vertex. These may, however, be invisible if no real tangent rays can be drawn from the centre of projection; and this happens when the ray projecting the centre of the vertex lies within the cone. In this case the traces of the cone are of importance. Thus in representing a cone of revolution with a vertical axis we get in the plan a circular trace of the surface whose centre is the plan of the vertex of the cone, and in the elevation the contour, consisting of a pair of lines intersecting in the elevation of the vertex of the cone. The circle in the plan and the pair of lines in the elevation do not determine the surface, for an infinite number of surfaces might be conceived which pass through the circular trace and touch two planes through the contour lines in the vertical plane. The surface becomes only completely defined if we write down to the figure that it shall represent a cone. The same holds for all surfaces. Even a plane is fully represented by its traces only under the silent understanding that the traces are those of a plane.

§ 48. Some of the simpler problems connected with the representation of surfaces are the determination of plane sections and of the curves of intersection of two such surfaces. The former is constantly used in nearly all problems concerning surfaces. Its solution depends of course on the nature of the surface.

To determine the curve of intersection of two surfaces, we take a plane and determine its section with each of the two surfaces, rabatting this plane if necessary. This gives two curves which lie in the same plane and whose intersections will give us points on both surfaces. It must here be remembered that two curves in space do not necessarily intersect, hence that the points in which their projections intersect are not necessarily the projections of points common to the two curves. This will, however, be the case if the two curves lie in a common plane. By taking then a number of plane sections of the surfaces we can get as many points on their curve of intersection as we like. These planes have, of course, to be selected in such a way that the sections are curves as simple as the case permits of, and such that they can be easily and accurately drawn. Thus when possible the sections should be straight lines or circles. This not only saves time in drawing but determines all points on the sections, and therefore also the points where the two curves meet, with equal accuracy.

§ 49. We give a few examples how these sections have to be selected.

A cone is cut by every plane through the vertex in lines, and if

it is a cone of revolution by planes perpendicular to the axis in circles.

A cylinder is cut by every plane parallel to the axis in lines, and if it is a cylinder of revolution by planes perpendicular to the axis in circles.

A sphere is cut by every plane in a circle.

Hence in case of two cones situated anywhere in space we take sections through both vertices. These will cut both cones in lines. Similarly in case of two cylinders we may take sections parallel to the axis of both. In case of a sphere and a cone of revolution with vertical axis, horizontal sections will cut both surfaces in circles whose plans are circles and whose elevations are lines, whilst vertical sections through the vertex of the cone cut the latter in lines and the sphere in circles. To avoid drawing the projections of these circles, which would in general be ellipses, we rabatt the plane and then draw the circles in their real shape. And so on in other cases.

Special attention should in all cases be paid to those points in which the tangents to the projection of the curve of intersection are parallel or perpendicular to the axis  $z$ , or where these projections touch the contour of one of the surfaces.

## PERSPECTIVE.

§ 50. We have seen that, if all points in a figure be projected from a fixed centre to a plane, each point on the projection will be the projection of all points on the projecting ray. A complete representation by a single projection is therefore possible only when there is but one point to be projected on each ray. This is the case by projecting from one plane to another, but it is also the case if we project the *visible* parts of objects in nature; for every ray of light meeting the eye starts from that point in which the ray, if we follow its course from the eye, backward meets for the first time any object. Thus, if we project from a fixed centre the *visible* part of objects to a plane or other surface, then the outlines of the projection would give the same impression to the eye as the outlines of the things projected, provided that one eye only be used and that this be at the centre of projection. If at the same time the light emanating from the different points in the picture could be made to be of the same kind—that is, of the same colour and intensity and of the same kind of polarization—as that coming from the objects themselves, then the projection would give sensibly the same impression as the objects themselves. The art of obtaining this result constitutes a chief part of the technique of a painter, who includes the rules which guide him under the name of perspective, distinguishing between *linear* and *aerial* perspective,—the former relating to the projection, to the *drawing* of the outlines, the latter to the colouring and the shading off of the colours in order to give the appearance of distance. We have to deal only with the former, which is in fact a branch of geometry consisting in the applications of the rules of projection.

§ 51. Our problem is the following:—*There is given a figure in space, the plane of a picture, and a point as centre of projection; it is required to project the figure from the point to the plane.*

From what has been stated about projection in general it follows at once that the projection of a point is a point, that of a line a line. Further, the projection of a point at infinity in a line is in general a finite point. Hence parallel lines are projected into a pencil of lines meeting at some finite point. This point is called the *vanishing point of the direction* to which it belongs. To find it, we project the point at infinity in one of the parallel lines; that is, we draw through the eye a line in the given direction. This cuts the picture plane in the point required.

Similarly all points at infinity in a plane are projected to a line (§ 6) which is called the *vanishing line of the plane* and which is common to all parallel planes.

All lines parallel to a plane have their vanishing points in a line, viz., in the vanishing line of the plane.

All lines parallel to the picture plane have their vanishing points at infinity in the picture plane; hence *parallel lines which are parallel to the picture plane appear in the projection as parallel lines in their true direction.*

The projection of a line is determined by the projection of two points in it, these being very often its vanishing point and its trace on the picture plane. The projection of a point is determined by the projection of two lines through it.

These are the general rules which we now apply. We suppose the picture plane to be vertical.

§ 52. Let (fig. 21)  $S$  be the centre of projection, where the eye is situated, and which in perspective is called the *point of sight*,  $ABKL$  the picture plane,  $ARMN$  a horizontal plane on which we suppose the objects to rest of which a perspective drawing is to be made. The lowest plane which contains points that are to appear in the picture is generally selected for this purpose, and is therefore called the ground plane, or sometimes the geometrical plane. It cuts the picture plane in a horizontal line  $AB$  called the ground line or base line or fundamental line of the picture. A horizontal line  $SV$ , drawn through the eye  $S$  perpendicular to the picture, cuts the latter at a point  $V$  called the centre of the picture or the centre of vision. The distance  $SV$  of the eye from the picture is often called the distance simply, and the height  $ST$  of the eye above the ground the height of the eye.

Fig. 21.

The vanishing line of the ground plane, and hence of every horizontal plane, is got by drawing the projecting rays from  $S$  to the points at infinity in the plane—in other words, by drawing all horizontal rays through  $S$ . The line in a horizontal plane which cuts the picture plane in a horizontal line  $DD'$  through the centre of vision  $V$ . This line is called the horizon in the picture. It contains the vanishing points of all horizontal lines, the centre of vision  $V$  being the vanishing point of all lines parallel to  $SV$ , that is perpendicular to the picture plane. To find the vanishing point of any other line we draw through  $S$  the ray projecting the point at infinity in the line; that is, we draw through  $S$  a ray parallel to the line, and determine the point where this ray cuts the picture plane. If the line is given by its plan on the ground plane and its elevation on the picture plane, then its vanishing point can at once be determined: it is the vertical trace of a line parallel to it through the eye (comp. § 35).

§ 53. To have construction in a single plane, we suppose the picture plane turned down into the ground plane; but before this is done the ground plane is pulled forward till, say, the line  $MN$  takes the place of  $AB$ , and then the picture plane is turned down. By this we keep the plan of the figure and the picture itself separate. In this new position the plane of the picture will be that of the paper (fig. 22). On it are marked the base line  $AB$ , the centre of vision  $V$ , and the horizon  $DD'$ , and also the limits  $ABKL$  of the actual picture. The eye, however, need not necessarily be marked. In the plan the picture plane must be supposed to pass through  $A_1B_1$ , and to be perpendicular to the ground plane. If we further suppose that the horizontal plane through the eye which cuts the picture plane in the horizon  $DD'$  be turned down about the horizon, then the centre of sight will come to the point  $S$ , where  $VS$  equals the distance of the eye.

Fig. 22.

To find the vanishing point of any line in a horizontal plane, we have to draw through  $S$  a line in the given direction and see where it cuts the horizon. For instance to find the vanishing points of the two horizontal directions which make angles of  $45^\circ$  with the horizon, we draw through  $S$  lines  $SD$  and  $SD'$  making each an angle of  $45^\circ$  with the line  $DD'$ . These points can also be found by making  $VD$  and  $VD'$  each equal to the distance  $SV$ . The two points  $D, D'$  are therefore called the distance points.

§ 54. Let it now be required to find the perspective  $P$  of a point  $P_1$  (figs. 21 and 22) in the ground plane. We draw through  $P_1$  two lines of which the projection can easily be found. The most convenient lines are the perpendicular to the base line, and a line making an angle of  $45^\circ$  with the picture plane. These lines in the

ground plan are  $P_1Q_1$  and  $P_1R_1$ . The first cuts the picture at  $Q_1$  or at  $Q$ , and has the vanishing point  $V$ ; hence  $QV$  is its perspective. The other cuts the picture in  $R_1$ , or rather in  $R$ , and has the vanishing point  $D$ ; its perspective is  $RD$ . These two lines meet at  $P$ , which is the point required. It will be noticed that the line  $QR = Q_1R_1 = Q_1P_1$  gives the distance of the point  $P$  behind the picture plane. Hence if we know the point  $Q$  where a perpendicular from a point to the picture plane cuts the latter, and also the distance of the point behind the picture plane, we can find its perspective. We join  $Q$  to  $V$ , set off  $QR$  to the right equal to the distance of the point behind the picture plane, and join  $R$  to the distance point to the left; where  $RD$  cuts  $QV$  is the point  $P$  required. Or we set off  $QR'$  to the left equal to the distance and join  $R'$  to the distance point  $D'$  to the right.

If the distance of the point from the picture should be very great, the point  $R$  might fall at too great a distance from  $Q$  to be on the drawing. In this case we might set off  $QW$  equal to the  $n$ th part of the distance and join it to a point  $E$ , so that  $VE$  equals the  $n$ th part of  $VD$ . Thus if  $QW = \frac{1}{4}QR$  and  $VE = \frac{1}{4}VD$ , then  $WE$  will again pass through  $P$ . It is thus possible to find for every point in the ground plane, or in fact in any horizontal plane, the perspective; for the construction will not be altered if the ground plane be replaced by any other horizontal plane. We can in fact now find the perspective of every point as soon as we know the foot of the perpendicular drawn from it to the picture plane, that is, if we know its elevation on the picture plane, and its distance behind it. For this reason it is often convenient to draw in slight outlines the elevation of the figure on the picture plane.

Instead of drawing the elevation of the figure we may also proceed as follows. Suppose (fig. 23)  $A_1$  to be the projection of the

Fig. 23.

plan of a point  $A$ . Then the point  $A$  lies vertically above  $A_1$  because vertical lines appear in the perspective as vertical lines (§ 51). If then the line  $VA_1$  cuts the picture plane at  $Q$ , and we erect at  $Q$  a perpendicular in the picture plane to its base and set off on it  $QA_2$  equal to the real height of the point  $A$  above the ground plane, then the point  $A_2$  is the elevation of  $A$  and hence the line  $A_2V$  will pass through the point  $A$ . The latter thus is determined by the intersection of the vertical line through  $A_1$  and the line  $A_2V$ .

This process differs from the one mentioned before in this that the construction for finding the point is not made in the horizontal plane in which it lies, but that its plan is constructed in the ground plane. But this has a great advantage. The perspective of a horizontal plane from the picture to the line at infinity occupies in the picture the space between the line where the plane cuts the picture and the horizon, and this space is the greater the farther the plane is from the eye, that is, the farther its trace on the picture plane lies from the horizon. The horizontal plane through the eye is projected into a line, the horizon; hence no construction can be performed in it. The ground plane on the other hand is the lowest horizontal plane used. Hence it offers most space for constructions, which consequently will allow of greater accuracy.

§ 55. The process is the same if we know the coordinates of the point, viz., we take in the base line a point  $O$  as origin, and we take the base line, the line  $OV$ , and the perpendicular  $OZ$  as axes of coordinates. If we then know the coordinates  $x, y, z$  measured in these directions, we make  $OQ = x$ , set off on  $QV$  a distance  $QA$  such that its real length  $QR = y$ , make  $QA_2 = z$ , and find  $A$  as before. This process might be simplified by setting off to begin with along  $OQ$  and  $OZ$  scales in their true dimensions and along  $OV$  a scale obtained by projecting the scale on  $OQ$  from  $D$  to the line  $OV$ .

§ 56. The methods explained give the perspective of any point in space. If lines have to be found, we may determine the perspective of two points in them and join these, and this is in many cases the most convenient process. Often, however, it will be advantageous to determine the projection of a line directly by finding its vanishing point. This is especially to be recommended when a number of parallel lines have to be drawn.

The perspective of any curve is in general a curve. The projection of a conic is a conic, or in special cases a line. The

perspective of a circle may be any conic, not necessarily an ellipse. Similarly the perspective of the shadow of a circle on a plane is some conic.

§ 57. A few words must be said about the determination of shadows in perspective. The theory of their construction is very simple. We have given, say, a figure and a point  $L$  as source of light. We join the point  $L$  to any point of which we want to find the shadow and produce this line till it cuts the surface on which the shadow falls. These constructions must in many cases first be performed in plan and elevation, and then the point in the shadow has to be found in perspective. The constructions are different according as we take as the source of light a finite point (say, the flame of a lamp), or the sun, which we may suppose to be at an infinite distance.

If, for instance, in fig. 23,  $A$  is a source of light,  $EHGF$  a vertical wall, and  $C$  a point whose shadow has to be determined, then the shadow must lie on the line joining  $A$  to  $C$ . To see where this ray meets the floor we draw through the source of light and the point  $C$  a vertical plane. This will cut the floor in a line which contains the feet  $A_1, C_1$  of the perpendiculars drawn from the points  $A, C$  to the floor, or the plans of these points. At  $C_1$ , where the line  $A_1C_1$  cuts  $AC$ , will be the shadow of  $C$  on the floor. If the wall  $EHGF$  prevents the shadow from falling on the floor, we determine the intersection  $K$  of the line  $A_1C_1$  with the base  $EF$  of the wall and draw a vertical through it, this gives the intersection of the wall with the vertical plane through  $A$  and  $C$ . Where it cuts  $AC$  is the shadow  $C'$  of  $C$  on the wall.

If the shadow of a screen  $CDD_1C_1$  has to be found we find the shadow  $D'$  of  $D$  which falls on the floor; then  $D_1D'$  is the shadow of  $D_1D$  and  $D'C'$  is the shadow on the floor of the line  $DC$ . The shadow of  $D_1D$ , however, is intercepted by the wall at  $L$ . Here then the wall takes up the shadow, which must extend to  $D''$  as the shadow of a line on a plane is a line. Thus the shadow of the screen is found in the shaded part in the figure.

§ 58. If the shadows are due to the sun, we have to find first the perspective of the sun, that is, the vanishing point of its rays. This will always be a point in the picture plane; but we have to distinguish between the cases where the sun is in the front of the picture, and so behind the spectator, or behind the picture plane, and so in front of the spectator. In the second case only does the vanishing point of the rays of the sun actually represent the sun itself. It will be a point above the horizon. In the other case the vanishing point of the rays will lie below the horizon. It is the point where a ray of the sun through the centre of sight  $S$  cuts the picture plane, or it will be the shadow of the eye on the picture. In either case the ray of the sun through any point is the line joining the perspective of that point to the vanishing point of the sun's rays. But in the one case the shadow falls away from the vanishing point, in the other it falls towards it. The direction of the sun's rays may be given by the plan and elevation of one ray.

For the construction of the shadow of points it is convenient first to draw a perpendicular from the point to the ground and to find its shadow on the ground. But the shadows of verticals from a point at infinity will be parallel; hence they have in perspective a vanishing point  $L_1$  in the horizon. To find this point, we draw that vertical plane through the eye which contains a ray of the sun. This cuts the horizon in the required point  $L_1$ , and the picture plane in a vertical line which contains the vanishing point of the sun's rays themselves. Let then (fig. 24)  $L$  be the vanishing

Fig. 24.

point of the sun's rays,  $L_1$  be that of their projection in a horizontal plane, and let it be required to find the shadow of the vertical column  $AH$ . We draw  $AL_1$  and  $EL$ ; they meet at  $E'$ , which is the shadow of  $E$ . Similarly we find the shadows of  $F, G, H$ . Then  $E'F'G'H'$  will be the shadow of the quadrilateral  $EFGH$ . For the shadow of the column itself we join  $E'$  to  $A$ , &c., but only mark the outlines;  $F'B$ , the shadow of  $BF$ , does not appear as such in the figure.

If the shadow of  $E$  has to be found when falling on any other surface we use the vertical plane through  $E$ , determine its inter-

section with the surface, and find the point where this intersection is cut by the line  $EL$ . This will be the required shadow of  $E$ .

§ 59. If the picture is not to be drawn on a vertical but on another plane—say, the ceiling of a room—the rules given have to be slightly modified. The general principles will remain true. But if the picture is to be on a curved surface the constructions become somewhat more complicated. In the most general case conceivable it would be necessary to have a representation in plan and elevation of the figure required and of the surface on which the projection has to be made. A number of points might also be found by calculation, using coordinate geometry. But into this we do not enter. As an example we take the case of a panorama, where the surface is a vertical cylinder of revolution, the eye being in the axis. The ray projecting a point  $A$  cuts the cylinder in two points on opposite sides of the eye, hence geometrically speaking every point has two projections; of these only the one lying on the half ray from the eye to the point can be used in the picture. But the other has sometimes to be used in constructions, as the projection of a line has to pass through both. Parallel lines have two vanishing points which are found by drawing a line of the given direction through the eye; it cuts the cylinder in the vanishing points required. This operation may be performed by drawing on the ground the plan of the ray through the foot of the axis, and through the point where it cuts the cylinder a vertical, on which the point required must lie. Its height above is easily found by making a drawing of a vertical section on a reduced scale.

Parallel planes have in the same manner a vanishing curve. This will be for horizontal planes a horizontal circle of the height of the eye above the ground. For vertical planes it will be a pair of generators of the cylinder. For other planes the vanishing curves will be ellipses having their centre at the eye.

The projections of vertical lines will be vertical lines on the cylinder. Of all other lines they will be ellipses with the centre at the eye. If the cylinder be developed into a plane, then these ellipses will be changed into curves of sines. Parallel lines are thus represented by curves of sines which have two points in common. There is no difficulty in making all the constructions on a small scale on the drawing board and then transferring them to the cylinder.

§ 60. A variety of instruments have been proposed to facilitate perspective drawings. If the problem is to make a drawing from nature then a camera obscura or, better, Wollaston's camera lucida may be used. Other instruments are made for the construction of perspective drawings. It will often happen that the vanishing point of some direction which would be very useful in the construction falls at a great distance off the paper, and various methods have been proposed of drawing lines through such a point. For some of these see Stanley's *Descriptive Treatise on Mathematical Drawing Instruments*.

*Literature.*—Descriptive geometry dates from Monge, whose *Géométrie Descriptive* appeared in 1800. Before his time plans and elevations, especially of buildings, had been in use, and rules had been developed to determine by construction from drawings the shapes of the stones required in buildings, especially in vaults and arches. These rules were reduced to a consistent method by Monge.

Perspective was investigated much earlier, as painters felt the need of it. Its beginnings date from the time of the Greek mathematicians, but its modern development from the time of the Renaissance, when the first books on the subject appeared in Italy. Albrecht Dürer also published a treatise on it and constructed a machine for making perspective drawings of objects. Of later writers we mention in the 17th century Desargues, and in the 18th Dr Brook Taylor, whose *Linear Perspective* appeared first in 1715 and *New Principles of Linear Perspective* in 1719. At present perspective is generally treated as a special case of projection, and included in books on descriptive geometry.

For the literature of projection in general, we refer to the list of books given under *GEOMETRY*, vol. x. p. 467. For descriptive geometry and perspective, see Monge, *Géométrie Descriptive*; Leroy, *Traité de Géométrie Descriptive*; Fiedler, *Darstellende Geometrie*; Gournerie, *Traité de Perspective*; Mannheim, *Géométrie Descriptive* (1880) and *Éléments de la Géométrie Descriptive* (1882); J. Woolley, *Descriptive Geometry* (1856), which is based on Leroy's work, and is the only scientific publication on the subject in England. A number of other publications with titles such as "Practical Geometry" and "Geometrical Drawing" contain more or less full explanations of the methods of descriptive geometry. These are based generally on Euclidian as opposed to projective geometry, and are therefore in their theoretical part more or less unsatisfactory. We may mention Angel, *Practical Plane Geometry and Projection*. (O. H.)

**PROJECTION OF THE SPHERE.** See **GEOGRAPHY**.

**PROME**, a district in Pegu division, British Burmah, India, between  $18^{\circ} 30'$  and  $19^{\circ} 15'$  N. lat., and  $94^{\circ} 40'$  and  $96^{\circ}$  E. long., containing an area of 2887 square miles. It occupies the whole breadth of the valley of the Irawadi, between Thayet district on the north and Henzada and Tharawadi districts on the south, and originally extended as far as the frontier of the province of Burmah, but in 1870 Thayet was formed into an independent jurisdiction. There are two mountain ranges in Promé, which form respectively the eastern and western boundaries. The Arakan Yoma extends along the whole of the western side, and that portion of the district lying on the right bank of the Irawadi is broken up by thickly wooded spurs

running in a south-easterly direction, the space for cultivation being but limited and confined to the parts adjacent to the river. On the eastern side lies the Pegu Yoma, and north and north-east of the district its forest-covered spurs form numerous valleys and ravines, the torrents from which unite in one large stream called the Na-weng river. The most important of the plains lie in the south and south-west portions of Prome, and extend along the whole length of the railway that runs between the towns of Pongdè and Prome; they are mostly under cultivation, and those in the south are watered by a series of streams forming the Myitma-kha or upper portion of the Hlaing. There are in addition large tracts of land covered by tree-jungle which are available for cultivation. The principal river is the Irawadi, which intersects the district from north to south; next in importance are the Tha-ni and its tributaries and the Na-weng system of rivers. In the hills near the capital the soil is of Tertiary formation, and in the plains it is of alluvial deposit. The climate is much drier than other districts in British Burmah. The total rainfall in 1882 was 49.64 inches.

In 1881 the population was 322,342 (161,433 males and 160,909 females). Buddhists and Jains numbered 313,261, Mohammedans 1795, Hindus 978, Christians 336, Aborigines 5518, and Parsees 5. More than two-thirds of the population are agriculturists. The chief towns are Prome (see below), and Shwedoong and Pongdè, with 12,373 and 6727 inhabitants respectively. The chief products are rice, teak, cutch, silk, sugar cane, cotton, tobacco, and sesame oil; but the staple product is rice, which is cultivated mainly in the Pongdè and Shwe-doung townships. The total area under cultivation in 1882 was 234,222 acres. One of the most important manufactures is silk; others are ornamental boxes, coarse brown sugar, and cutch. The gross revenue of the district in 1882 amounted to about £92,000, of which over a third was derived from the land.

The early history of the once flourishing kingdom of Prome, like that of the other states which now form portions of the province of British Burmah, is veiled in obscurity. Fact and fable are so interwoven that it is impossible to disentangle the true from the false. After the conquest of Pegu in 1755 by Aloung-bhura, the founder of the third and present dynasty of Ava kings, Prome remained a province of the Burman kingdom till the close of the second Burmese war in 1853, when the province of Pegu was annexed to British territory.

PROME, chief town of the above district, on the left bank of the Irawadi, had a population in 1881 of 28,813 (males 14,982, females 13,831). To the south and south-east the town is closed in by low pagoda-topped hills, on one of which stands the conspicuous gilded Shwe Tsan-daw. The town was taken by the British in 1825 and again in 1852, on both occasions with hardly any opposition from the Burmese. In 1862 it was almost entirely destroyed by fire, and was afterwards relaid out in straight and broad streets. It was erected into a municipality in 1874, and since then great improvements have been made. Its principal manufactures are silk cloths and lacquer ware.

PROMETHEUS, son of the Titan Iapetus by the sea nymph Clymene, is the chief "culture hero," and, in some accounts, the Demiurge of Greek mythical legend. As a culture-hero or inventor and teacher of the arts of life, he belongs to a wide and well-known category of imaginary beings. Thus Qat, Quahteht, Pundjel, Maui, Ioskeha, Cagn, Wainamoinen, and an endless array of others represent the ideal and heroic first teachers of Melanesians, Ahts, Australians, Maoris, Algonquins, Bushmen, and Finns. Among the lowest races the culture-hero commonly wears a bestial guise, is a spider (Melanesia), an eagle hawk (Australia), a coyote (north-west America), a dog or raven (Thlinket), a mantis insect (Bushman), and so forth, yet is endowed with human or even superhuman qualities, and often shades off into a permanent and practically deathless god. Prometheus, on the other hand, is purely anthropomorphic. He is the friend and

benefactor of mankind. He defends them against Zeus, who, in accordance with a widely diffused mythical theory, desires to destroy the human race and supplant them with a new and better species, or who simply revenges a trick in which men get the better of him. The pedigree and early exploits of Prometheus are given by Hesiod (*Theog.*, 510-616). On a certain occasion gods and men met at Mecone. The business of the assembly was to decide what portions of slain animals the gods should receive in sacrifice. On one side Prometheus arranged the best parts of the ox covered with offal, on the other the bones covered with fat. Zeus was invited to make his choice, chose the fat, and found only bones beneath. A similar fable of an original choice, in which the chooser is beguiled by appearances, recurs in Africa and North America. The native tribes adapt it to explain the different modes of life among themselves and white men. In wrath at this trick, according to Hesiod, or in other versions for the purpose of exterminating the remnants of people who escaped the deluge of Deucalion, Zeus never bestowed, or later withdrew, the gift of fire. In his "philanthropic fashion," Prometheus stole fire, concealed in a hollow fennel stalk (Hesiod, *Op. et Di.*), and a fennel stalk is still used in the Greek islands as a means of carrying a light (*cf.* Pliny, *xiii.* 22). According to some legends he gained the fire by holding a rod close to the sun. Probably the hollow fennel stalk in which fire was carried got its place in myth from the very fact of its common use.

We thus find Promethens in the position of the fire-bringer, or fire-stealer, and so connected with a very wide cycle of similar mythical benefactors. Among the Murri of Gippsland, to begin with a backward people, the fire-stealer was a man, but he became a bird *Tou-e-ra*, or fire, was in the possession of two women who hated the blacks. A man who loved men cajoled the women, stole fire when their backs were turned, and was metamorphosed into "a little bird with a red mark on its tail, which is the mark of fire." The fire-bringer in Brittany is the golden or fire-crested wren. Myths like this kill two birds with one stone, and at once account for the possession of fire by men and for the marking of certain animals regarded as fire-bringers.<sup>1</sup> In another Australian legend fire was stolen by the hawk from the bandicoot, and given to men. In yet another a man held his spear to the sun, and so got a light. A bird is fire-bringer in an Andaman island tale, and a ghost in another myth of the same island.<sup>2</sup> In New Zealand, Maui stole fire from Mauika, the lord of fire. He used a bird's intervention. Among the Ahts, in North America,<sup>3</sup> fire was stolen by animals from the cuttle-fish. Among the Thlinkets, Yehl, the raven-god, was the fire-stealer. Among the Cahrocs, the coyote steals fire from "two old women." Among the Aryans of India, Soma is stolen by birds, as water is among the Thlinkets, and mead in the Edda.<sup>4</sup> Fire concealed himself, in the Veda, was dragged from his hiding place by Matarigran, and was given to the priestly clan of Bhrigu. We also hear that Matarigran "brought fire from afar" (*R. V.*, iii. 9, 5), and that Bhrigu found fire lurking in the water (*R. V.*, x. 46, 2).<sup>5</sup>

In considering the whole question, one must beware of the hasty analogical method of reasoning too common among mythologists. For example, when a bird is spoken of as the fire-bringer we need not necessarily conclude that, in each case, the bird means lightning. On the other hand, the myth often exists to explain the cause of the markings of certain actual species of birds. Again, because a hero is said to have stolen or brought fire, we need not regard that hero as the personification of fire, and explain all his myth as a fire-myth. The legend of Prometheus has too often been treated in this fashion, though he is really a culture hero, of whose exploits, such as making

PROPAGANDA, or Sacred Congregation *de Propaganda Fide*, is the name given to a commission of cardinals appointed for the direction of the missions of the Roman Church. The idea of forming such an institution was conceived by Pope Gregory XIII. and other pontiffs, but it was Gregory XV. (1621-1623) who, after having sought counsel from cardinals and information concerning the state of religion in various countries from apostolic nuncios and superiors of religious orders, published, 22nd July 1622, the bull *Inscrutabile* by which he founded the Congregation of Propaganda and provided means for its continuance. The cardinal vicar and the cardinal secretary of state were amongst its first members. Additional privileges were granted it by other bulls; and all the pontifical colleges founded up to that date as well as those which should afterwards be founded for the propagation of the faith were declared subject to the Propaganda. The deliberations of this body, embracing a great variety of important questions, when formulated in decrees and signed by the cardinal prefect and the secretary were declared by Urban VIII., in 1634, to have the force of apostolic constitutions, which should be inviolably observed. The cardinal prefect is the head of the Congregation, and as such governs the Catholic missions of the world; the secretary is assisted by five subalterns (*minutanti*), who act as heads of departments, and these again are assisted by inferior employees (*scrittari*). The more important acts of the Congregation, which are discussed in weekly meetings by the cardinal prefect and the officials, are submitted to the pope for his supreme decision. The archives of the institution were transferred, in 1660, from the Vatican to the Palazzo Farnesini in the Piazza di Spagna, Rome, which is the seat of the Congregation. They form a valuable collection of historical, ethnographical, and geographical documents, embracing a period of two hundred and fifty years, and serve as a record of past events and of precedents to be followed in decisions on questions that may arise. The funds of the institution were supplied in the first instance by Gregory XV. and by private bequests. Cardinal Barberini, brother of Urban VIII., provided for eighteen places in perpetuity for students, Mgr. Vives for ten. Pope Innocent XII. bequeathed to it 150,000 crowns in gold; Clement XII. gave it 70,000 crowns. In the second assembly of the Congregation it was proposed, and accepted as a rule, that prelates on being raised to the dignity of cardinal should pay for a ring offered them by the pope a sum which was at first fixed at 545 golden *scudi*, and which is now 600 Roman *scudi*. Large donations were made to the Propaganda by Catholics in England, Scotland, Ireland, the United States, Spain, and Italy. The cardinal prefect administers the property of the institution in the name of the Congregation. To provide for the affairs of the Church of the Oriental Rite, Pius IX., in 1862, appointed a special Congregation with its own secretary, consultants, and officials.

The primary purpose of the Propaganda being to secure laborious and pious missionaries, colleges for their education and training were established. Chief amongst these is the Propaganda or Urban College in Rome, so named from Urban VIII. It is a general missionary seminary for the whole world. Here students are received from all foreign nations, and there are special foundations for Georgian, Persian, Chaldean, Syrian, Coptic, Brahman, Abyssinian, Armenian, Greek, and Chinese students, as well as for students from England, Ireland, America, and Australia, although these last have special colleges in Rome. After the age of fourteen each student takes an oath to serve the mission during his whole life in the ecclesiastical province or vicariate assigned to him by the Congregation, to which

he must send annually an account of himself and of his work. He is maintained and clothed free of expense. His studies embrace the full course of Greek, Latin, and Italian letters, some of the chief Oriental languages, as Hebrew, Syriac, Arabic, Armenian, and, when necessary, Chinese. There are also schools for the teaching of rational and natural philosophy, a complete course of theology, and the institutions of canon law. Besides this principal seminary, the Propaganda has colleges dependent on it both in Rome and in other countries, under the direction of regular and secular priests. From its beginning it had at its disposition national colleges,—such as the English, founded by Gregory XIII.; the Irish, by Cardinal Ludovisi in 1628; the Scotch, by Clement VIII. in 1600; the German and Hungarian; the American, of the United States, opened by Pius IX. in 1859; the Greek, founded by Gregory XIII.; the Armenian, recently established by Leo XIII.; and the Bohemian, opened 4th November 1884. The jurisdiction of the Propaganda extends over the English colleges of Lisbon and Valladolid, the Irish college of Paris, and the American of Louvain. Until recently it had the Chinese college of Naples, transformed by the Italian Government, and the Illyrian college of Loreto, suppressed by the same Government; and it still has the Albanian pontifical college of Scutari. Besides these, other colleges serve for the education of missionaries for the Propaganda, as the college of SS. Peter and Paul in Rome, founded by Pius IX., in Milan the seminary of St Calocero for all foreign missions, and at Genoa the College Brignole Sale for Italian emigrants to America. The institutions at Verona for central Africa are the support of the missions in the Soudan. Chief of all the seminaries is that of Paris which, for two centuries, has supplied missionaries for India and China. To these is committed the vast college of the island of Pulo Penang, where young men from China and neighbouring countries are trained to the priesthood. In Paris many missionaries are taken from the French seminary directed by the fathers of the Congregation of the Holy Ghost, who go to French colonies. At Lyons is the college for African missions. In Belgium there are the colleges of Foreign Missions, of the Immaculate Conception, and of St Francis Xavier for Chinese missions. In Holland there was recently established the college of Stiel, whose students go to China. In All Hallows College, Ireland, the students are educated for the missions in Australia, Canada, and the Cape of Good Hope. In England a seminary has grown up within a few years at Mill Hill, which has already supplied priests to the missions of Borneo and Madras. Previous to the late changes in Rome, the Propaganda had dependent upon it the college of Reformed Minors in S. Pietro in Montorio, the Carmelites in S. Pancrazio (suppressed), the Minor Observants of S. Bartolomeo all' Isola recently re-established, the Conventuals (suppressed), and the Irish Minor Franciscans of St Isidore. Outside of Rome there were also colleges of regulars for the missions, as Ocaña in Spain, Sernache in Portugal, and others. The Propaganda, in the establishment of vicariates or new episcopal sees, has always encouraged the formation, as soon as circumstances would permit, of seminaries for the education of a native clergy, and frequently these have flourished, as the community of the "Houses of God" (*case di Dio*) in Tongking, the seminaries of Sze-chuen, of Peking, and of Nanking. The first step taken in a new mission is the erection of a chapel, followed by the opening of a school and an orphanage. As numbers increase, and more priests come to the new mission, they are united under a superior invested with special powers by the Propaganda—in fact a prefect apostolic. As churches increase and the faith spreads, a vicar apostolic, who is a bishop *in partibus*, is appointed,

and, if the progress made requires it, the mission is erected into an episcopal diocese. Such has been the method of proceeding in the American and Canadian missions; such, in part, what has happened in India, China, and Africa. Through these, whether prefects or vicars apostolic or bishops, the orders of the Propaganda, which are those of the head of the church, are transmitted to the faithful, and they are the ordinary centres of its correspondence, although it does not disdain the reports furnished by the humblest members of the Christian flock. The prelates furnish exact reports to the Propaganda of the progress and circumstances of the faith in their various missions.

The material means for the diffusion of the faith are supplied in the first place by special grants from the revenues of the Propaganda and from various associations in Europe. The greatest part is furnished by the society for the propagation of the faith of Paris and Lyons. This society is independent of the Propaganda, relying wholly on the energy of the two central councils of Paris and Lyons and on the charity of the faithful, though it attends to the suggestions of the Propaganda, which indicates to it the needs of new missions. Contributions are also furnished by other associations, as that of the Holy Infancy, or that for the education of Oriental nations. Similar societies, occupied with the support of special missions, exist in Bavaria, Germany, and Austria. The Propaganda likewise takes care that, as soon as a mission is established, pious foundations are constituted by native Christians, and become the local property of the church, and so supply it with a stable and enduring vitality. Subscriptions from Europe are given only to the poorer missions, which, however, are very numerous. One of the most powerful aids adopted by the Propaganda in the diffusion of the faith is the printing-press. The missionaries are required to study the languages of the countries to which they are sent and exhorted to publish books in these languages. Printing-presses are introduced into new missions. In China, what may be described as wooden stereotypes are employed for the printing of Catholic works in the Chinese language. Early in its career the Congregation of Propaganda established at its seat in Rome the celebrated Polyglott Printing Press, and gave it a character of universality. There people of all nations—the Copt, the Armenian, the Arab, the Hebrew, the Japanese, and the native of Malabar—may find books in their native tongue and in their special type. Although great progress has been made by other countries in polyglott printing, the Propaganda press still holds a high position.

The part of the world to which the cardinals of the Congregation of Propaganda first turned their attention was Asia. In no region of the globe has Christianity had greater difficulties to struggle against than in China. An ancient tradition exists, confirmed by documents, that in the early centuries of the Christian era Christianity had penetrated into and left traces in China. It was re-introduced in the 13th century by Franciscan fathers. It flourished at Peking for a time, but died out with the Mongolian dynasty, and China remained closed to Christian influences until 1555, when the Dominican father Gaspare della Croce introduced it into the province of Canton. After he was expelled came the Jesuits Rogeri and Ricci. They established a residence there in 1579, and were followed by Dominicans and Franciscans. These were succeeded a century later by the priests of the Paris seminary of foreign missions, in the last century by Augustinians and Lazarists, and in the present century by the missionaries of the seminary of St Calocero of Milan. Two bishoprics were created in 1688, one at Nanking, the other at Peking, and the missions of Yun-nan and Szechuen founded. At the beginning of the 18th century

the number of churches in the northern provinces reached 300, and of Christians 300,000. In 1803 a college for native clergy was opened in Sze-chuen, and the work of the Holy Infancy introduced. In 1837 the Portuguese patronage of Chinese missions was brought to an end, with the exception of that exercised over Macao, a Portuguese colony.

In 1310 B. Odorico di Friuli, a Franciscan, entered Tibet and made many converts. In 1624 Father D'Andrada penetrated into the same country, but was not allowed to remain. Others followed, and were put to death. In 1847 the Propaganda entrusted to the seminary of foreign missions the task of entering Tibet, and in 1857 a vicariate apostolic was erected on the frontiers. In Mongolia, constituted a vicariate apostolic in 1840, many converts were made and several priests educated in the seminary of Siwang-se. This mission offers great hopes. It was divided into three vicariates in 1883, and is entrusted to the Belgian congregation of the Immaculate Heart of Mary. The Manchuria mission was made a vicariate in 1839; in 1854 a church, S. Maria ad Nives, was erected, and many other churches have since been built for the increasing mission. In 1592 an attempt was made to Christianize Corea; but repeated persecutions crushed out the germs of Christianity. Its first neophyte, its first native priest, its first bishops, and its first European missionaries were martyrs. From 1784 to 1789 4000 Coreans were converted, but their number was greatly reduced by persecution. In 1831 a vicariate was established; in 1835 the number of Christians was 6280; in 1861 they reached 18,000; but in 1866 persecution began anew. Christianity was introduced into Japan in 1549 by S. Francis Xavier. In less than fifty years there were in Japan a bishopric, 380 churches, and 30,000 professing Christians. Persecution broke out in 1601, and in 1614 became so fierce that the priests were put to death and the people dispersed. In 1640 all Europeans, missionaries included, were banished from Japan, this proscription continuing for two centuries. Missionaries were admitted in 1843, but so jealously watched that little good was accomplished. In 1863 a treaty was concluded between the emperor of the French and the Japanese Government permitting the preaching of the gospel. The first church was built after a lapse of two centuries; the number of catechumens soon reached 10,000; other churches were constructed; and the descendants of the old Christians, who had still preserved the faith, came forth from their concealment. A new persecution broke out in 1870: many Christians apostatized; a great number died of hunger, and many were exiled. Peace was established in 1873. The vicariate apostolic was divided in 1876 into two—the northern and southern vicariates. By the treaty of Peking, concluded between the French and Chinese Governments, liberty of religion was granted in the Chinese empire and a new era opened. In 1873, in the eighteen provinces of the Chinese empire, the number of Catholics was 410,644, with 4054 centres, 1220 churches and public chapels, 294 bishops and missionaries, 252 native priests, 137 European female religious and 924 native, 104 orphanages with 6853 orphans, and 947 schools frequented by 10,624 pupils. In spite of popular tumults and persecutions these numbers have increased in late years.

In the year of its foundation the Propaganda established a prefecture apostolic in Burmah. Italian Barnabites penetrated into the country in 1721, and two of them, Fathers Gallizio and Nerici, were put to death. The priests of the seminary of foreign missions continue the work, and three vicariates have been established. Malacca was visited by S. Francis Xavier, and was for a long time under the Portuguese jurisdiction; but a vicariate was

PROPERTIUS. Sextus, the greatest Roman poet of Rome, was born of a good Umbrian family, who were considerable landed proprietors in the fair and fertile region between Perugia and the river Tiber. The name of Propertius is at a birth of a V. The temples of the famous St. Francis, and St. Elizabeth Propertius' home. The year of his birth uncertain, and he has been variously placed between 55 and 45 B.C. He came from one of the 22 of Ovid that Propertius was his son, but also his friend and companion; from a poet of that name lived in the service of Augustus, following Gallus, who was born in 65 B.C., and Terence, who lived in the 1st century to 55 B.C., and immediately preceding Ovid himself, who was a contemporary, was born 45 B.C. He fell out of favor with Augustus, and was banished 59 B.C., a date which agrees well with the indications of the poems themselves. His early life was full of misfortune. He hated his father before he died, and died a death followed by poverty. After the battle of Philippi and the return of Octavian to Rome, the victorious legions had to be provided for; their clamorous need and capacity of demand he appeared by moderate agrarian concessions, and the north of Italy had to be surrendered. In connection with his fellow poets Virgil and Horace, Propertius was the prince of his estate; but, unlike these, he had no patron, no court, and he was reduced from opulence to our present indigence. The idea of the poet's life, which was the province of the triumph, and his life, the province of the triumph. The insurrection which is generally known as the rebellion

India is one of the most extensive fields in which the missionaries have laboured. Previous to the founding of the Propaganda the Jesuits had established several missions in India. The introduction of their apostolic work dated the basis of Christianity, and now twenty-three vicars apostolic and a delegate apostolic direct the spiritual affairs of this great country. In Africa Catholic missionaries were the first travellers, two centuries prior to Livingstone and Stanley. The earliest mission was that of Turis (1624). The mission of the Cape of Good Hope were entrusted to the clergy of Mauritius; the Reformati and the Obervants went to Egypt, the Carmelites to Mozambique and Madagascar, the Capuchins and Jesuits

*Perusinum* from its only important incident, the fierce and fatal resistance of Perugia, deprived the poet of another of his relations, who was killed by brigands while making his escape from the lines of Octavian. The loss of his patrimony, however, thanks no doubt to his mother's providence, did not prevent Propertius from receiving a superior education. After or, it may be, during its completion he and she left Umbria for Rome; and there, about the year 34 B.C., he assumed the garb of manly freedom. He was urged to take up a pleader's profession; but the serious study went against the grain, and, like Ovid, he found in letters and gallantry a more congenial pursuit. Soon afterwards he made the acquaintance of Lycinna, about whom we know little beyond the fact that she subsequently excited the jealousy of Cynthia, and was subjected to all her powers of persecution (*vezandi*). This passing fancy was succeeded by a serious attachment, the object of which was the famous "Cynthia." Her real name was Hostia, and she was a native of Tibur. She was a courtesan of the superior class, somewhat older than Propertius, and seems to have been a woman of singular beauty and varied accomplishments. Her own predilections led her to literature; and in her society Propertius found the intellectual sympathy and encouragement which were essential for the development of his powers. Her character, as depicted in the poems, is not an attractive one; but she seems to have entertained a genuine affection for her lover. The intimacy began in 28 and lasted till 23 B.C. These six years must not, however, be supposed to have been a period of unbroken felicity. Apart from minor disagreements, an infidelity on Propertius's part excited the deepest resentment in Cynthia; and he was banished for a year. The quarrel was made up about the beginning of 25 B.C.; and soon after Propertius published his first book of poems and inscribed it with the name of his mistress. Its publication placed him in the first rank of contemporary poets, and amongst other things procured him admission to the literary circle of Mæcenas. The intimacy was renewed; but the old enchantment was lost. Neither Cynthia nor Propertius was faithful to the other. The mutual ardour gradually cooled; motives of prudence and decorum urged the discontinuance of the connexion; and disillusion changed insensibly to disgust. Although this separation might have been expected to be final, it is not certain that it was so. It is true that Cynthia, whose health appears to have been weak, does not seem to have survived the separation long. But a careful study of the seventh poem of the last book, in which Propertius gives an account of a dream of her which he had after her death, leads us to the belief that they were once more reconciled, and that in her last illness Cynthia left to her former lover the duty of carrying out her wishes with regard to the disposal of her effects and the arrangements of her funeral. Almost nothing is known of the subsequent history of the poet. He was certainly alive in 16 B.C., as some of the allusions in the last book testify. And there are two passages in the letters of the younger Pliny in which he speaks of a descendant of the poet, one Passennus Paullus. Now in 18 B.C. Augustus carried the *Leges Juliae*, which offered inducements to marriage and imposed disabilities upon the celibate. It would seem therefore at least a natural conclusion that Propertius was one of the first to comply with the provisions of the law, and that he married and had at least one child, from whom the contemporary of Pliny was descended.

Propertius appears to have had a large number of friends and acquaintances, chiefly literary, belonging to the circle of Mæcenas. Amongst these may be mentioned Virgil, the epic poet Ponticus, Bassus (probably the iambic poet of the name), and at a later period Ovid. He does not seem to have come across Tibullus; and his relations with

Horace were not particularly friendly. Horace may have regarded him as an interloper in the favour of Mæcenas; though there is nothing in the poems of Propertius to warrant the supposition. In person Propertius was pale and thin, as was to be expected in one of a delicate and even sickly constitution. He was very careful about his personal appearance, and paid an almost foppish attention to dress and gait. He was of a somewhat voluptuous and self-indulgent temperament, which shrank from danger and active exertion. He was anxiously sensitive about the opinion of others, eager for their sympathy and regard, and, in general, impressionable to their influence. His over-emotional nature passed rapidly from one phase of feeling to another; but the more melancholy moods predominated. A vein of sadness runs through his poems, sometimes breaking out into querulous exclamation, but more frequently venting itself in gloomy reflexions and prognostications. He had fits of superstition which in healthier moments he despised. It must be added that the native weakness of his character was no doubt considerably increased by his infirm and delicate constitution.

The poems of Propertius, as they have come down to us, consist of four books containing 4046 lines of elegiac verse. The unusual length of the second one (1402 lines) has led Lachmann and other critics to suppose that it originally consisted of two books, and they have placed the beginning of the third book at ii. 10, a poem addressed to Augustus. This theory, somewhat modified, has been powerfully advocated by Th. Birt (*Das Antike Buchwesen*, pp. 413-426). He divides the poems into two parts,—a single book (lib. i.), published separately and called *Cynthia Monobiblos*, as in the MSS. and the lemma to Martial (xiv. 189), and a *Tetrabiblos Syntaxis*, a collection of four books, published together, consisting of the remainder of his poems. If this view is correct, the greater part of the first book of the *Syntaxis* must have been lost, as ii. 1-9 only contain 354 lines. The first book, or *Cynthia*, was published early in the poet's literary life, and may be assigned to 25 B.C. The date of the publication of the rest is uncertain, but none of them can have been published before 24 B.C., and the last, at any rate, was probably published posthumously. The subjects of the poems are threefold:—(1) amatory and personal, mostly regarding Cynthia—seventy-two (sixty Cynthia elegies), of which the last book contains three; (2) political and social, on events of the day—thirteen, including three in the last book; (3) historical and antiquarian—six, of which five are in the last book.

The writings of Propertius are noted for their difficulty; and this has undoubtedly prejudiced his reputation as a poet. His style seems to unite every element by which a reader could be deterred. Not to speak of the unequal quality of his workmanship, in which curtness alternates with redundancy, and carelessness with elaboration, the indistinctness and discontinuousness of his thought is a serious strain upon the attention. An apparently desultory sequence of ideas, sudden and often arbitrary changes of subject, frequent vagueness and indirectness of expression, a peculiar and abnormal Latinity, a constant tendency to exaggeration, and an excessive indulgence in learned and literary allusions,—all these are obstacles lying in the way of a study of Propertius. But those who have the will and the patience to surmount them will find their trouble well repaid. In power and compass of imagination, in freshness and vividness of conception, in truth and originality of presentation, few Roman poets can compare with him. If these qualities are <sup>scarcely</sup> <sup>at all</sup> eminent for long together, if his flights are rarely <sup>long</sup> <sup>steady</sup> and sustained, this is matter for regret rather than <sup>irritate</sup> <sup>cavil</sup> or even astonishment. Propertius was essentially <sup>incapable</sup>

of self-criticism, constitutionally intolerant of the slow labour of the file. His work is ever best when done under the urgency of a supreme and rapid excitement, and when, so to say, the discordant qualities of his genius are fused together by the electric spark of an immediate inspiration. Two of his merits seem to have impressed the ancients themselves. The first is most obvious in the scenes of quiet description and emotion in whose presentation he particularly excels. Softness of outline, warmth of colouring, a fine and almost voluptuous feeling for beauty of every kind, and a pleading and almost melancholy tenderness—such were the elements of the spell which he threw round the sympathies of his reader, and which his compatriots expressed by the vague but expressive word *blatitia*. His *furor*, or command of striking and appropriate language, is more noticeable still. Not only is his vocabulary very extensive, but his employment of it extraordinarily bold and unconventional. New settings of use, idiom, and construction continually surprise us, and, in spite of occasional harshness, secure for his style an unusual freedom and freedom. His handling of the elegiac couplet, and especially of its second line, deserves especial recognition. It is vigorous, varied, and even picturesque. In the matter of the rhythms, caesuras, and elisions which it allows, the metrical treatment is much more severe than that of Catullus, whose elegiacs are comparatively rude and barbarous; but it is not beyond hand and foot, like that of the Ovidian distich, in a formal and conventional system. It only now remains to call attention to the elaborate symmetry of construction which is observable in many of his elegies. Often indeed the correspondence between different parts of his poem is so close that critics have endeavoured with more or less success to divide them into strophes.

Propertius's poems bear evident marks of the study of his predecessors in both Greek and Latin, and of the influence of his contemporaries. He tells us himself that Callimachus and Philotas were his masters, and that it was his ambition to be the Roman Callimachus. We can trace obligations to Theocritus, Apollonius Rhodius, and other Alexandrians, but above all to Melager, and amongst earlier writers to Homer, Pindar, Æschylus, and others. Among Latin writers he had read with more or less care the works of Ennius, Lucretius, the dramatists, and Catullus. We find coincidences too close to be fortuitous between his poems and those of Virgil, Horace, and Tibullus his contemporaries; but it is very possible the influence was reciprocal. Propertius's influence upon his successors was considerable. There is not a page of Ovid which does not show obligations to his poems, while other writers made a more modest use of his stores. Among these may be mentioned Manilius, Juvenal, Martial, Statius, Claudian, Seneca, and Apuleius.

The works of Propertius have come down to us in a far from perfect condition. Some of the poems have been lost; others are fragmentary; and most are more or less disfigured by corruptions. The manuscripts on which we have to rely are late and in several cases interpolated; and these circumstances, combined with the native difficulty of the poet's writing, make the task of his restoration and interpretation one of peculiar delicacy and difficulty.

Dionatus (or Suetonius) in his life of Virgil, 20 (45), is the authority for the full name of Propertius. "Aurelius" and "Nauta," which are added in the MSS., are due to confusion with Prudentius, and a corrupt reading of iii. 19, 22 (Müller), (ii. 21, 22, Palmer).—On the Propertii, see Mommsen in *Herms*, iv. p. 370; Haupt, *Opus*, i. p. 252. Besides the Propertius Æneus (the Pæneus Paulus of Pliny), we hear of a C. Propertius who was *triumvir capitulis* and *pæneus* in the time of Augustus, and a Propertius Celer, a poor senator under Tiberius. Inscriptions of the Propertii have been found at Aesii, cf. Hertzberg, *Prop.*, i. pp. 10-12.

Propertius tells us himself that his family was not "noble," iii. 32 (ii. 31), 55, 6, and iii. 19, 7, c.—Merania (Bevagna) and Hispellum (Spello) have been put forward as the birth-place of Propertius, but the poet's own expressions are decisive for Aesii. Apart from the question of reading in v. (iv.) 1, 125 (MSS. Asis.), the climbing walls of his town (*rescendentes arces, scandens murus*, v. (iv.) 1, 65 and 7, c.), its nearness to Perugia, and its position close above the plain (i. 22, 9, 10) are altogether unsuitable to Spello and Bevagna.—Ovid thus assigns Propertius his place:—*successor fuit hic (Tibullus), tibi, Galle: Propertius illi (Tibullus): quartus ab his serie temporis ipse fuit* (*Tr.*, iv. 10, 53, 54); and again (*ib.*, ii. 467), his (to Tibullus and Propertius) *posterior*. For Ovid's friendship with Propertius see below.—v. 1, 121 *sq.* is the chief authority for the earlier events of his life. For the premature death of his father and the loss of his property, see 127 *sq.*:—*ex æque legisti non illa ætate legenda patris et in tunc, cogeris ipse Læres. nam tibi cum multi versarent mura iuvenis abstulit excultas pericla tristis opes*. Elsewhere he says that he is non ita diues (iii. 19 (22), 7, c.), and that he had nulla domi fortuna relicta, iii. 32, 55, 7, c. Indirect evidence, such as his living on the Esquiline, iv. (iii.) 23, 24, points to a competence. For the death of his kinsman, generally supposed to be the Gallus of i. 21, see i. 22, 5-8. Propertius's mother is mentioned in ii. 8, 39; iii. 13, 15; and in very affectionate terms in i. 11, 21. She was dead when iii. 13 (11) was written, i.e., six months after the publication of the first book. For the quality of Propertius's education, the poems themselves are the only, but a sufficient, testimony.—For Lycinna see iv. 14 (iii. 15), 3-10, 43.—Cynthia, or Hostia (Apul., *Apul.*, p. 416) of Tibur (v. (iv.), 7, 85), was the granddaughter (iv. 19 (iii. 20), 6) of L. Hostius, who wrote a poem on the Illyrian war of 178 B.C., of which some fragments are preserved. She was much older than Propertius (iii. 10 (ii. 18), 29). That she was a *meretrix* is clear from many indications—her accomplishments, her house in the Subura, the occurrence of scenes like those in i. 3, iii. 27 (ii. 29), the fact that Propertius could not marry her, &c. For descriptions of her beauty see ii. 2, 5 *sq.*, and 3, 9 *sq.*; iii. 3 (ii. 13), 23, 24; her poetry, ii. 3, 21; and other accomplishments, i. 2, 27 *sq.*, iv. 19 (20), 7, 8. In character she was fickle (i. 15, ii. 6, &c.), greedy (iii. 8 (ii. 16), 11, 12, Cynthia non acquiritur sacra, nec curat honores: semper amatum potenter una sinu), and fond of money (ii. 3, 15, 16); her temper was violent, iv. 7 (iii. 8), &c., and led her to slander those who had offended her (i. 4, 18 *sq.*, &c.).—For the five years, see iv. (iii.) 25, 3, quinque tibi potui servire fideliter annos; and for the year of separation, iv. 15, 11 (iii. 16), 9, peccaram semel, et totum annum pulsus in annum. The second separation is vouched for by the two last elegies of book iv. The evidence which v. (iv.) 7 furnishes in favour of a reconciliation is analysed by Poëpate (*Prop.*, Introd., p. xxv. *sq.*).—v. 6 commemorates the celebration of the *ludi quinquennales*, and v. 11, 66 alludes to the consulship of P. Scipio in 16 B.C. For Pæneus Paulus (or as an Aesii inscription calls him C. Pæneus Sergius Paulus Propertius Æneus), see Pliny (*Ep.*, vi. 15), municipi Propertii atque etiam inter maiores Propertium numerat; (9, 22), in litteris uterque æmulatur exprimit reddidit: Propertium in primis a quo genus ducit, vera sololes coque simillima illi in quo ille præcipuus, si elegos eius in manum sumptis, leges opus terrum molle incusculum et plane in Propertii domo scriptum.—ii. 1 and iv. (iii.) 9 are addressed to Mæcenæ, iii. 1 (ii. 10) to Augustus. Virgil is spoken of in the highest terms in iii. 32 (ii. 24), 61 *sq.* Other poems are addressed to Ponticus (i. 7, 9), Lævus (i. 4), Lynceus a tragic poet (iii. 32, ii. 34). Volpi conjectured (in his edition of Propertius, i. pp. xv. *sq.*) that the inquisitive fellow of Horace, *Sat.*, i. 9; but the conjecture is generally rejected on grounds of chronology. It has recently been rediscovered and rejected by Prof. A. Palmer in his edition of Horace's *Satires*, i. 9 (notes), p. 219. In *Ep.* ii. 87 *sq.*, however, Horace seems to make a direct attack on Propertius.—On Propertius's personal appearance, see i. 1, 22, 5, 21; pallorem nostrum . . . cur sim toto corpore nullus ego. A likeness of him has possibly been preserved in a double Hermes in the Villa Albani and the Vatican, which represents a young beardless Roman, of a nervous and somewhat sickly appearance, in combination with a Greek poet, possibly Callimachus or Philotas (Visconti, *Iconograph. Romana*, plate 14, 3, 4; see E. Brizio, *Annal. dell' inst. arch.*, 1873, 105; C. Robert, *Arch. Ztg.*, 33, 35, cited by Teuffel). His health is proved, as well by the specific allusion of i. 15 as by the frequent references to death and burial—i. 19; ii. 1, 71 *sq.*; iii. 5, 1 (ii. 13, 17) *sq.* For his care about dress and the like, see ii. 4, 16, 16, (5, 6), nequiquam perfusa mihi unguenta capillis ibat et expenso planta morata gradu. His character is mirrored in his poems. In particular it has had a great deal to do in moulding his vocabulary (Postgate, Introd., p. xxxvi. *sq.*). For want of courage and energy, especially, see ii. 7, 14; iii. 12 (ii. 19), 17-24; and for superstitious leanings iii. 23 (ii. 27); ii. 4, 16, (25); v. (iv.) 5, 9, *sq.*—The numbering of the books is one of the most vexed questions of Propertius; but it is not unlikely that Birt's conclusions will be ultimately accepted. The dates of the several poems

ure, where known, some guide towards determining that of the books: i. 8 seems to have been written about 27 B.C.; i. 6 not before 27 B.C.; ii. 1 in 25 B.C.; i. 8 after 27 B.C.; iii. 1 (ii. 10) in 24 B.C.; 29, 31, end of 25; 32 not before 23 B.C.; iv. (iii.) 17 (15) in or after 23 B.C.; so 3 (4), 4 (5), 11 (12), but 20 about 23 B.C.; v. (iv.) 6, 11 not before 16 B.C.; 3 in 23 B.C. For the evidence for believing book v. to be posthumous see Postgate, pp. liv., lv.—It is beyond our limits to discuss the style and idiom of Propertius in full. For details see Hertzberg, Introduction, pp. 47, sq.; Postgate, Introduction, pp. lvii. sq. (literary style), lxxxviii. sq. (grammar and vocabulary), cxxvi. sq. for metre and prosody; also L. Müller's Introduction, pp. xlviii. sq. For ancient references to Propertius as a writer see Quint., x. 1, 93, where it is stated that some (not Quintilian) preferred him to Tibullus, Ov., A. A., iii. 333, Tr., iii. 465 (blandus P.), v. 1, 17 (blandus), Mart., xiv. 183 (facundus P.), viii. 73, Pliny, l.c. above, Stat., *Silv.*, i. 2, 233, Vmbro Propertius antro.—Prop., iii. (iv.) 1, Callimachi Manes et Coi sacra Philetas, in uestrum, quaeso, me sinite ire nemus; v. (iv.) 1, 64, Vmbria Rom. ni patria Callimachi. But, as is well pointed out by Teuffel in his *History of Roman Literature*, Propertius's debt to Callimachus and Philetas is chiefly a formal one. Even into his mythological learning he breathes a life to which those dry scholars were complete strangers.—For a summary account of his relations to his predecessors and contemporaries see Postgate, *Introduct.* ch. v. Coincidences with Horace are quoted in Teuffel (§ 246, 2); with Catullus, M. Magnus, *Fleckeisen's Jahrbücher*, 115, p. 418; with Tibullus, A. Zingerle, *Ovid's Verhältnisse*, &c., i. 55, 98, 101, &c.; with Virgil, Nettleship, *Ancient Lives of Vergil*, p. 63, 64.

There is no existing MS of Propertius older than the 14th century. Up till the publication of Bährens's edition (1850), the Neapolitanus (N.), now often called the Guelpherbytanus was regarded as the best. Bährens, however, maintained its worthlessness as compared with the concurrence of four other MSS. of his own collating:—Vossianus, circa 1360 (A); Laurentianus, beginning of 15th century (F); Ottobonianus-Vaticanus, end of 14th century (V); Darentiensis, 1410-20 (D). Bährens's attack upon the Neapolitan was answered by H. Leo (*Ph. Mus.*, xxi. 471), Ellis (*Amer. Journ. Phil.*, i. 359), Palmer (*Hermathena*, iv. 48-72). The contending merits of these MSS. have been examined by Solbisky (*Comm. Phil. Jemurae*, ii. 1743) with considerable care, and his conclusions as to the independent value both of N. and the consensus of D. V. are likely to be accepted.

The *editio princeps* of Propertius is that of 1472, Venice. Among the chief editions may be mentioned the following, those with notes being marked with an asterisk:—Scaliger (1577, &c.), \*Broekhusius (2d ed., 1577), \*Passeratius (1608), \*Volpius (1705, 2 vols.), \*P. Burmann (and Santen) (1780), \*Lachmann (1816; text only, 1829), \*Jacob (1827), Hertzberg (1843-45, 2 vols.), \*F. A. Paley (2d ed., 1872), L. Müller (1870), Haupt-Vahlen (1879), Bährens (1880), A. Palmer (1880); selections, with introduction, Postgate (1891). Those of Müller and Palmer are the editions cited throughout this article. It is impossible to cite the numerous programs, dissertations, papers, &c., which have been published on subjects connected with Propertius. For fuller bibliographies it is sufficient to refer to Hertzberg, *Prop.*, i. pp. 249-59; Engelmann's *Bibliotheca Scriptorum Latinorum* (ed. Preuss.) i. 322; J. E. B. Mayor's *Bibliographical Clue to Latin Literature* (1875); W. Teuffel, *Geschichte d. Röm. Literatur* (2d ed., 1892; Eng. trans., 1873; acc. 246 gives an excellent account of Propertius); Pauly, *Real-Encyclopädie*, s.v. "Propertius." Reviews of recent Propertian literature are given in Bursian's *Jahresbericht* (1873), pp. 1447-54 (very meagre), and in the *Trans. Camb. Philol. Soc.*, 1880 (i. 372-86), 1891-92 (ii. 226-36).

The following translations into English verse are known:—G. F. Nott, Book I. (published anonymously, 1872); C. A. Elton, selections in his *Spectimens of the Classic Poets*, vol. II. p. 215 sq. (1814, reprinted along with the preceding and a prize version by P. J. F. Gantillon, in Bohn's series, 1848, 1859); C. R. Moore (London, 1870); J. Craustoun (Edinburgh, 1875); F. A. Paley, verse translations from Book v. with notes (1866); also a few translations by Gray (the poet) first printed in Greville's edition, vol. I. (1894).

PROPHET (προφήτης) is a word taken from the vocabulary of ancient Greek religion, which passed into the language of Christianity, and so into the modern tongues of Europe, because it was adopted by the Hellenistic Jews as the rendering of the Hebrew נָבִיא (*nābî*, pl. *nēbîm*). The word therefore as we use it is meant to convey an idea which belongs to Hebrew and not to Hellenic belief; but when it first underwent this change of application the age of the *nēbîm* was long past, and the Jews themselves had a very imperfect conception of what they had been and done. Hence in actual usage the idea conveyed by the word prophet has never quite corresponded with its historical prototype; the prophets of early Christendom, for example, are not by any means exact counterparts of the Old-Testament prophets, and in general very various ideas have prevailed as to what a prophet is or should be, because up to quite a recent date the work of the Hebrew prophets has been habitually approached not in a purely historical spirit but under the influence of preconceived ideas.<sup>1</sup>

<sup>1</sup> It does not appear that the original Hellenic associations of the word have had any sensible effect on these ideas. According to Plato (*Timaeus*, p. 72) the name προφήτης ought properly to be confined to the interpreters employed to put an intelligible sense on the dreams,

In the present article no attempt will be made to follow those speculations about the nature of prophecy which belong to dogmatic theology rather than to history; but a brief sketch will be given (1) of the history of Hebrew prophecy (in supplement to what has been already said in the article ISRAEL or is to be found in the articles devoted to individual prophets), and (2) of prophecy in the early Christian Church. To speak of more recent religious phenomena within Christendom which have claimed to be prophetic would carry us too far; for them the reader is referred to such articles as MONTANISM, ANABAPTISTS. The conception of prophecy on which the Mohammedan religion is built has been sufficiently explained in the life of Mohammed; borrowed, somewhat unintelligently, from later Judaism, it is radically different from that of the Old Testament, and when narrowly looked at lends no countenance to the statement often made, and at first sight plausible, that prophecy is a phenomenon characteristic of Semitic religion in general.

1. *The Prophets of the Old Testament.*—The author of 1 Sam. ix. 9 tells us that "beforetime in Israel, when a man went to inquire of God, thus he spake, Come and let us go to the seer; for he that is now called a prophet (*nābî*) was beforetime called a seer." This remark is introduced to explain how his contemporaries spoke of Samuel. He was a "seer" (ver. 11), or, as he is also called (ver. 6 sq.), a "man of God," that is one who stood in closer relations to God than ordinary men; "all that he said was sure to come to pass," so that he could be consulted with advantage even in private matters like the loss of the asses of Kish. The narrative of 1 Sam. ix. is so vivid and exact that not many generations of oral tradition can have separated the writer from the events he records; it shows us therefore, at least broadly, what the word prophet meant in the early times of the Hebrew kingdom, and it shows us that it had acquired that meaning after the age of Philistine oppression in which Samuel lived, and to which his younger contemporaries Saul and David put an end. That this is the sense of the author, and that we must not suppose that the word prophet had merely become more common in his time and supplanted an older synonym, appears beyond question a few verses further down, where we see that there were already in Samuel's time people known as *nēbîm*, but that they were not seers. The seer, with his exceptional insight, is a man of prominent individuality and held in great respect: when Saul asks for the seer every one knows that there is only one person in the town whom he can mean. With the prophets it is quite otherwise; they appear not individually but in bands; their prophesying is a united exercise accompanied by music, and seemingly dance-music; it is marked by strong excitement, which sometimes acts contagiously, and may be so powerful that

visions, or enigmatic utterances of the frenzied *μάντις*. But in ordinary Greek usage the prophet of any god is in general any human instrument through whom the god declares himself; and the tendency was "to reserve the name for unconscious interpreters of the divine thought, and for the ministers of the oracles in general" (Bouché-Leclercq, *Hist. de la Divination* [1880], ii. 11). This probably facilitated the adoption of the term by the Hellenists of Alexandria, for, when Philo distinguishes the prophet from the spurious diviner by saying that the latter applies his own inferences to omens and the like while the true prophet, rapt in ecstasy, speaks nothing of his own, but simply repeats what is given to him by a revelation in which his reason has no part (ed. Manger, ii. 321 sq., 343; comp. i. 510 sq.), he follows the prevalent notion of the later Jews, at least in so far as he makes the function of the prophet that of purely mechanical reproduction; compare John xi. 51, and the whole view of revelation presupposed in the Apocalyptic literature. But in any case the Greek language hardly offered another word for an organ of revelation so colourless as προφήτης, while the condition of etymology among the ancients made it possible to interpret it as having a special reference to prediction (so Eusebius, *Dem. Ev.*, v., deriving it from προφάτω).

he who is seized by it is unable to stand,<sup>1</sup> and, though this condition is regarded as produced by a divine afflatus, it is matter of ironical comment when a prominent man like Saul is found to be thus affected. Samuel in his later days appears presiding over the exercises of a group of *nabim* at Ramah, where they seem to have had a sort of covenanted (Naboth), but he was not himself a *nabi*—that name is never applied to him except in 1 Sam. xiii. 21, where it is plainly used in the later sense for the idea which in Samuel's own time was expressed by "seer."

But again the *nabim* seem to have been a new thing in Israel in the days of Samuel. Surely there had been of old as in other primitive nations; of the two Hebrew words literally corresponding to our seer, *rosh* and *hosh*, the second is found also in Arabic, and seems to belong to the primitive Semitic vocabulary.<sup>2</sup> But the enthusiastic bands of prophets are nowhere mentioned before the time of Samuel; and in the whole previous history the word prophet occurs very rarely, never in the very oldest narratives, and always in that sense which we know to be later than the age of Samuel, so that the use of the term is due to writers of the age of the kings who spoke of ancient things in the language of their own day. The appearance of the *nabim* in the time of Samuel was, it would seem, as has been explained in the article ISRAEL, one manifestation of the deep pulse of suppressed indignant patriotism which began to beat in the hearts of the nation in the age of Philistine oppression, and this fact explains the influence of the movement on Saul and the interest taken in it by Samuel. The ordinary life of ancient Israel gave little room for high-strung religious feeling, and the common acts of worship combined with the annual harvest and vintage feasts or similar occasions of natural gladness, with which no strain of abnormal enthusiasm could well be combined. It was perhaps only in time of war, when he felt himself to be fighting the battles of Jehovah, that the Hebrew was stirred to the depths of his nature by emotions of a religious colour. Thus the deeper feelings of religion were embodied in warlike patriotism, and these feelings were embodied in warlike patriotism, and these feelings the Philistine oppression had raised to extreme tension among all who loved liberty, while yet the want of a captain to lead forth the armies of Jehovah against his foes deprived them of their natural outlet. It was this tense suppressed excitement, to which the ordinary acts of worship gave no expression, which found vent in the enthusiastic services of the companies of prophets. In its external features the new phenomenon was exceedingly like what is still seen in the East in every *akt* of dervishes—the enthusiasm of the prophets expressed itself in no artificial form, but in a way natural to the Oriental temperament. Processions with pipe and hand-drum, such as that described in 1 Sam. x, were indeed a customary part of ordinary religious feasts; but there they were an outlet for natural merriment, here they have changed their character to express an emotion more sombre and more intense, by which the prophets, and often mere chance spectators too, were so overpowered that they seemed to lose their old personality and to be swayed by a supernatural influence. More than this hardly lies in the expression "a divine spirit" (רוח מן ה' which is used not only of the prophetic afflatus but of the evil frenzy that afflicted Saul's later days. The Hebrews had a less narrow conception of the spiritual than we are apt to read into their records.

To give a name to this new phenomenon the Israelites, it would seem, had to borrow a word from their Canaanite neighbours. At all events the word *nabi* is rather part of the old Semitic vocabulary (in Arabic it is a late loan word), nor has it any etymology in Hebrew, the cognate words "to prophesy" and the like being derived from the noun in its technical sense. But we know that there were *nabim* among the Canaanites; the "prophets" of Baal appear in the history of Elijah as men who sought to attract their god by wild orgiastic rites. In fact the presence of an orgiastic character is as marked a feature in Canaanite religion as the absence of it is in the oldest religion of Israel; but the new Hebrew enthusiasts had at least an external resemblance to the devotees of the Canaanite sanctuaries, and this would be enough to determine the choice of a name which in the first instance seems hardly to have been a name of honour.<sup>4</sup> In admitting that the name was borrowed, we are not by any means shut up to suppose that the Hebrew *nabim* simply copied their Canaanite neighbours. The phenomenon is perfectly intelligible without any such hypothesis. A wave of intense religious feeling passes over the land and finds its expression, according to the ordinary law of Oriental life, in the formation of a sort of enthusiastic religious order. The Nazarites and the Rechabites are parallel phenomena, though of vastly inferior historical importance.

The peculiar methods of the prophetic exercises described in 1 Samuel were of little consequence for the future development of prophecy. The heat of a first enthusiasm necessarily cooled when the political conditions that produced it passed away; and, if the prophetic associations had done no more than organize a new form of spiritual excitement, they would have only added one to the many mechanical types of hysterical religion which are found all over the East. Their real importance was that they embodied an intenser vein of feeling than was expressed in the ordinary feasts and sacrifices, and that the greater intensity was not artificial, but due to a revival of national sentiment. The worship of the local sanctuaries did nothing to promote the sense of the religious unity of Israel; Jehovah in the age of the Judges ran no small risk of being divided into a number of local Beals, givers of natural good things each to his own locality. The struggle for freedom called forth a deeper sense of the unity of the people of the one Jehovah, and in so doing raised religion to a loftier plane; for a faith which unites a nation is necessarily a higher moral force than one which only unites a township or a clan. The local worship, which subsisted unchanged during the greater part of the Hebrew kingship, gave no expression to this rise in the religious consciousness of the nation; on the contrary we see from the prophetic books of the 8th century that they lagged more and more behind the progress of religious thought. But the prophetic societies were in their origin one symptom of that upheaval of national life of which the institution of the human sovereign reigning under the divine King was the chief fruit; they preserved the traditions of that great movement; they were, in however imperfect a way, an organ of national religious feeling, and could move forward with the movement of national life. And so, though we cannot follow the steps of the process, we are not surprised to

<sup>1</sup> 1 Sam. ii. 37, xiii. 21. In the latter passage read "they saw the favour of the prophets as they prophesied, &c." (see Hoffmann in Stalder's *Zeltzer*, 1883, p. 82), after the Syriac.

<sup>2</sup> On grounds of etymology indeed both this passage and 1 Sam. xiii. 21, where at v. 6 prophets appear as revelers (seers), are held to be part of the old stock of the history of Samuel.

<sup>3</sup> Hoffmann, *ut supra*, p. 92.

<sup>4</sup> If this account of the origin of the *nabim* is correct (comp. Rosen, *Prophets*, Eng. tr., p. 554 ff.), the etymological sense of the word *nabi* is comparatively unimportant. The root seems to mean "to start up," "to rise into prominence," and so "to become ardent"; but the range of possible explanations of the noun which remains open is too great to give value to any conjecture. The leading views are collected in several of the books cited at the close of this article, and a fresh and interesting investigation is given in G. Hoffmann's article quoted above.

learn that they soon had an established footing in Israel, and that the prophets came to be recognized as a standing sacred element in society. What was their precise place in Hebrew life we hardly know, but they formed at least a religious class which in all its traditions represented the new national and not the old communal and particularistic life. One characteristic point which appears very early is that they felt themselves called upon to vindicate the laws of divine righteousness in national matters, and especially in the conduct of the kings, who were not answerable to human authority. The cases of Nathan and David in the matter of Uriah, of Elijah and Ahab after the judicial murder of Naboth, will occur to every one, and from the Hebrew standpoint the action of Gad in the matter of the census taken by David belongs to the same category. Such interventions with an Eastern king demanded great moral courage, for, though to some extent protected by their sacred character, the persons of the prophets were by no means legally inviolable (1 Kings xix. 2; xxii. 27; 2 Kings vi. 31). Another point of the first importance in the development of the class was the absorption into it of the old seers, which, as we have already seen, must have occurred comparatively early. The great prophecy of Nathan (2 Sam. vii.) is of too disputed a date to be cited in evidence, but already in David's time we find that Gad the *nābī* is also the king's seer (2 Sam. xxiv. 11; comp. 1 Sam. xxii. 5), and by and by it comes to be clearly understood that the prophets are the appointed organ of Jehovah's communications with His people or His king. The rise of this function of the prophets is plainly parallel with the change which took place under the kings in the position of the priestly oracle; the Torah of the priests now dealt rather with permanent sacred ordinances than with the giving of new divine counsel for special occasions. Jehovah's ever-present kingship in Israel, which was the chief religious idea brought into prominence by the national revival, demanded a more continuous manifestation of His revealing spirit than was given either by the priestly lot or by the rise of occasional seers; and where could this be sought except among the prophets? It does not of course follow that every one who had shared in the divine afflatus of prophetic enthusiasm gave forth oracles; but the prophets as a class stood nearer than other men to the mysterious workings of Jehovah, and it was in their circle that revelation seemed to have its natural home. A most instructive passage in this respect is 1 Kings xxii., where we find some four hundred prophets gathered together round the king, and where it is clear that Jehoshaphat was equally convinced, on the one hand that the word of Jehovah could be found among the prophets, and on the other that it was very probable that some or even the mass of them might be no better than liars. And here it is to be observed that Micaiah, who proved the true prophet, does not accuse the others of conscious imposture; he admits that they speak under the influence of a spirit proceeding from Jehovah, but it is a lying spirit sent to deceive. The sublime and solitary figure of Elijah, whom we are apt to take as the typical figure of a prophet in the old kingdom, has little in common with the picture even of the true prophet which we derive from 1 Kings xxii.; and when his history is carefully and critically read it is found to give no reason to think that he stood in any close relation to the prophetic

<sup>1</sup> It does not follow from the fact that the word of revelation is older than the separation of theocratic organs; Moses indeed the interpreters en.

is not only prophet and priest but judge and ruler. But as the history goes on the prophet stands out more and more as the typical organ of revelation, the type of the man who is Jehovah's intimate, sharing His secrets (Amos ii. 7; Jer. xxiii. 22), and ministering to Israel the gracious guidance which distinguishes it from all other nations (Amos ii. 11; Hosea xii. 10, 13), and also the sentences of awful judgment by which Jehovah rebukes rebellion (Hos. vi. 5). The full development of this view seems to lie between the time of Elijah and that of Amos and Hosea,—under the dynasty of Jehu, when prophecy, as represented by Elisha and Jonah, stood in the fullest harmony with the patriotic efforts of the age. This growth in the conception of the prophetic function is reflected in parts of the Pentateuch which may be dated with probability as belonging to the period just named; the name of *nābī* is extended to the patriarchs as Jehovah's intimates (Gen. xx. 7), and Moses begins to be chiefly looked at as the greatest of prophets (Num. xi. xii.; Deut. xxxiv. 10), while Aaron and Miriam are also placed in the same class (Exod. xv. 20; Num. xii.) because they too are among the divinely favoured leaders of Israel (comp. Micah vi. 4).<sup>1</sup>

Elisha, the successor of Elijah, stood in much closer relations to the prophetic societies than his great master had done. As a man of practical aims he required a circle through which to work, and he found this among the prophets, or, as they are now called, the sons of the prophets. According to Semitic idiom "sons of the prophets" most naturally means "members of a prophetic corporation,"<sup>2</sup> which may imply that under the headship of Elisha and the favour of the dynasty of Jehu, which owed much to Elisha and his party, the prophetic societies took a more regular form than before. The accounts we have certainly point in this direction, and it is characteristic that in 2 Kings iv. 42 first fruits are paid to Elisha. But to an institution like prophecy national recognition, royal favour, and fixed organization are dangerous gifts. It has always been the evil fate of the Hebrews to destroy their own highest ideals by attempting to translate them into set forms, and the ideal of a prophetic guidance of the nation of Jehovah could not have been more effectually neutralized than by committing its realization to the kind of state church of professional prophets, "eating bread" by their trade (Amos vii. 12),<sup>3</sup> which claimed to inherit the traditions of Elijah and Elisha. The sons of the prophets appear to have been grouped round the leading sanctuaries, Gilgal, Bethel, and the like (comp. Hos. ix. 8), and to have stood in pretty close relation to the priesthood (Hos. iv. 5), though this comes out more clearly

<sup>1</sup> None of these passages belong to the very oldest thread of Pentateuchal story, and similarly Deborah is called prophetess only in the later account (Jud. iv. 4), not in the song (Jud. v.). It is characteristic that in Num. xi. the elders who receive a share in Moses's task also receive a share of his prophetic spirit (comp. the parallel 2 Kings ii. 9 sq.). In the older account (Exod. xviii.) this is not so. A gain Moses differs from all other prophets in that Jehovah speaks to him face to face, and he sees the similitude of Jehovah. This is in fact the difference between him and Elijah (comp. Exod. xxxiii. 8-11; 1 Kings xix. 13), but not between him and the great prophets of the 8th century (Isa. vi. 5). That prophecy was generally given in visions, dreams, and obscure sentences is true only of an early period. The Amos still has frequent visions of a more or less enigmatic character, as Micaiah had, but there is little trace of this in the great prophets who succeed him. On the psychological reasons for this see W. R. Smith, *The prophets of Israel* (1882), p. 221 sq.

<sup>2</sup> See G. Hoffmann, *Kirchenversammlung zu Ephesus* (1873), p. 58.

<sup>3</sup> Those who consulted the old seers were expected to make a present, 1 Sam. ix. 7 (Arabic *holwānu-l-kāhin*; comp. Bokhari, iv. 219). Similar presents were brought to the older prophets (1 Kings x. 25; 2 Kings x. 25), and first fruits were sometimes paid to a man of God; but the successors of Amos share his contempt for those who trade in oracles (Mic. iii. 5 sq.).

for the southern kingdom, where, down to the last days of Hebrew independence, the official prophets of Jerusalem were connected with the temple and were under the authority of the chief priest (Jer. xxix. 26). Since the absorption of the aborigines in Israel Canaanite ideas had exercised great influence over the sanctuaries—so much so that the reforming prophets of the 8th century regarded the national religion as having become wholly heathenish; and this influence the ordinary prophets, whom a man like Micah regards as mere diviners, had certainly not escaped. They too were, at the beginning of the Assyrian period, not much more different from prophets of Baal than the priests were from priests of Baal. Their God had another name, but it was almost forgotten that He had a different character.

The rise and progress of the new school of prophecy, beginning with Amos and continued in the succession of canonical prophets, which broke through this religious stagnation, has already been discussed in the article ISRAEL (vol. xiii. p. 410 *sq.*); for from Amos and still more from Isaiah downwards the prophets and their work make up the chief interest of Hebrew history. From this time, moreover, the prophets appear as authors; and their books, preserved in the Old Testament, form the subject of special articles (AMOS, HOSEA, &c.). A few observations of a general character will therefore suffice in this place.

Amos disclaimed all connexion with the mere professional prophets, and in this he was followed by his successors. Formerly the prophets of Jehovah had been all on the same side: their opponents were the prophets of Baal. But henceforth there were two parties among the prophets of Jehovah themselves, the new prophets accusing the old of impotence and disloyalty to Jehovah, and these retaliating with a charge of disloyalty to Israel. We have learned to call the prophets of the new school "true" prophets and their adversaries "false"; and this is perfectly just if we take the appellations to mean that the true prophets maintained a higher and therefore a truer view of Jehovah's character, purpose, and relation to His people. But the false prophets were by no means mere common impostors; they were the accredited exponents of the common orthodoxy of their day—and even of a somewhat progressive orthodoxy, for the prophets who opposed Jeremiah took their stand on the ground of Josiah's reformation, and plainly regarded themselves as conservators of the prophetic traditions of Isaiah, whose doctrine of the inviolability of Jehovah's seat on Zion was the starting point of their opposition to Jeremiah's predictions of captivity. No doubt there were many conscious hypocrites and impostors among the professional prophets, as there always will be among the professional representatives of a religious standpoint which is intrinsically untenable, and yet has on its side the prestige of tradition and popular acceptance. But on the whole the false prophets deserve that name, not for their conscious impostures, but because they were content to handle religious formulas which they had learned by rote as if they were intuitive principles, the fruit of direct spiritual experience, to enforce a conventional morality, shutting their eyes to glaring national sins, after the manner of professional orthodoxy, and in brief to treat the religious *status quo* as if it could be accepted without question as fully embodying the unchanging principles of all religion. The popular faith was full of heathenish superstition strangely blended with the higher ideas which were the inheritance left to Israel by men like Moses and Elijah; but the common prophets accepted all alike, and combined heathen arts of divination and practices of mere physical enthusiasm with a not altogether insincere pretension that

through their professional oracles the ideal was being maintained of a continuous divine guidance of the people of Jehovah.

Amos and his successors accepted the old ideal of prophecy if they disowned the class which pretended to embody it. "The Lord Jehovah will do nothing, but He revealeth His secret to His servants the prophets." "By a prophet Jehovah brought Israel out of Egypt, and by a prophet" in each successive age Israel had been watched over and preserved. But in point of fact the function of the new prophecy was not to preserve but to destroy Israel, if Israel still meant the actual Hebrew nation with its traditional national life. Till Amos prophecy was optimist—even Elijah, if he denounced the destruction of a dynasty and the annihilation of all who had bowed the knee to Baal, never doubted of the future of the nation when only the faithful remained; but the new prophecy is pessimist—it knows that Israel is rotten to the core, and that the whole fabric of society must be dissolved before reconstruction is possible. And this it knows, not by a mere ethical judgment on the visible state of society, but because it has read Jehovah's secret written in the signs of the times and knows that He has condemned His people. To the mass these signs are unintelligible, because they deem it impossible that Jehovah should utterly cast off His chosen nation; but to those who know His absolute righteousness, and confront it with the people's sin, the impending approach of the Assyrian can have only one meaning and can point to only one issue, viz., the total ruin of the nation which has denied its divine head. It is sometimes proposed to view the canonical prophets as simple preachers of righteousness; their predictions of woe, we are told, are conditional, and tell what Israel must suffer if it does not repent. But this is an incomplete view; the peculiarity of their position is that they know that Israel as it exists is beyond repentance. Only, while they are hopeless about their nation they have absolute faith in Jehovah and His purpose. That cannot be frustrated, and, as it includes the choice of Israel as His people, it is certain that, though the present commonwealth must perish, a new and better Israel will rise from its grave. Not the reformation but the resurrection of Israel is the goal of the prophets' hope (Hos. vi. 1 *sq.*).

This of course is only the broadest possible statement of a position which undergoes many modifications in the hands of individual seers, but on the whole governs all prophecy from Amos to Jeremiah. The position has, we see, two sides: on the one side the prophets are heralds of an inexorable judgment based on the demands of absolute righteousness; on the other they represent an assured conviction of Jehovah's invincible and gracious love. The current theological formula for this two-sided position is that the prophets are at once preachers of the law and forerunners of the gospel; and, as it is generally assumed that they found the law already written, their originality and real importance is made to lie wholly in their evangelical function. But in reality, as has been shown in ISRAEL and PENTATEUCH, the prophets are older than the law, and the part of their work which was really epoch-making for Israel is just the part which is usually passed over as unimportant. By emphasizing the purely moral character of Jehovah's demands from Israel, by teaching that the mere payment of service and worship at Jehovah's shrines did not entitle Israel's sins to be treated one whit more lightly than the sins of other nations, and by enforcing these doctrines through the conception that the approach of the all-destroying empire before which Israel must fall equally with all its neighbours was the proof of Jehovah's impartial righteousness, they gave for the first

time a really broad and fruitful conception of the moral government of the whole earth by the one true God.<sup>1</sup>

It is impossible to read the books of the older prophets, and especially of their protagonist Amos, without seeing that the new thing which they are compelled to speak is not Jehovah's grace but His inexorable and righteous wrath. That that wrath must be followed by fresh mercies is not in itself a new thought, but only the necessary expression of the inherited conviction that Jehovah, whom they preach as the judge of all the earth, is nevertheless, as past history has proved, the God who has chosen Israel as His people. That this is so appears most clearly in the fact that with Amos the prophecy of restoration appears only in a few verses at the end of his book, and in the still more instructive fact that neither he nor Hosea attempts to explain how the restoration which they accept as a postulate of faith is to be historically realized.<sup>2</sup> One point only in their picture of the great restoration appears to present the germ of an historical principle. The Israel of the future is to be one united nation as in the days of David. The Davidic kingdom is accepted by both prophets, and by Hosea even more explicitly than by Amos, as the type of the future kingdom of Jehovah. But one sees from the way in which this thought is handled that it is the idea of that kingdom as it was in days of old which is before the prophet's mind; the actual state of Judah, which was not religiously better than the greater Israel, though it perhaps still possessed elements of greater political and social stability, was not such as to suggest the thought that when Samaria fell the continuity of Jehovah's relations with His people could be preserved at Jerusalem. It was in the great northern kingdom—still Israel *par excellence*—not in the petty region that had remained loyal to David, that the drama of divine justice and mercy was to be acted to its end: to Hosea, at least in his later prophecies, the fate of Judah does not appear separable from that of the northern realm—when Israel and Ephraim fall by their iniquity Judah must fall with them (Hos. v. 5). Thus even on this side there is no real bridge over the chasm that separates the total ruin impending over the Israel of the present from the glorious restoration of the Israel of the future. There is a unity in the divine purpose, of which judgment and mercy are the two poles, but there is as yet no conception of an historical continuity in the execution of that purpose, and therefore no foundation laid for the maintenance of a continuous community of faith in the impending fall of the nation.

From this we can see the enormous importance of the work of Isaiah as it has been exhibited in the article ISRAEL, vol. xiii. p. 413 *sq.*; his doctrine of the remnant, the holy seed, never lost to the nation in the worst times, never destroyed by the most fiery judgments, supplies the lacking element of continuity between the Israel of the present and of the future. Jehovah's kingdom cannot perish even for a time; nay, Isaiah argues that it must remain visible, and visible not merely in the circle of the like-minded whom he had gathered round him and who

<sup>1</sup> It must not be supposed that this conception necessarily came into force as soon as it was recognized that Jehovah was the creator of the universe. That the national or tribal god is the creator is an idea often found in very low religions. To us God's sovereignty over nature often seems the hardest thing to conceive; but to primitive peoples who know nothing of laws of nature His moral sovereignty is a much more difficult conception. In the older literature of the Hebrews the nearest approach to the thought of Amos and Hosea is not Gen. ii. iii., but Gen. xviii. 25.

<sup>2</sup> Ho-*ea* ii. 14 *sq.*, xi. 10 *sq.* are not solutions of this difficulty, as appears from their metaphorical form. They tell us that Jehovah will call His people and that they will answer; but this is only putting in another form the axiom that the gifts and calling of God are without repentance.

formed the first germ of the notion of the church, but in the political form of a kingdom also. Zion at least, the sacred hearth of Jehovah, the visible centre of his kingdom, must remain inviolable; it can never be delivered into the hands of the Assyrian. Thus, with Isaiah in the days of Sennacherib's invasion, the prophetic word became again, as it had been in the days of the Syrian wars, "the chariots and horsemen of Israel," the stay and strength of all patriotic hope.

Yet even at this crisis the resemblance between Isaiah and Elisha, between the new prophecy and the old, is more apparent than real. Elisha still stands firmly planted on the old national conception of the religion of Jehovah; his ideals are such as do not lie beyond the range of practical politics. In doing battle against the Tyrian Baal he is content with a reformation for which the whole nation can be heartily won, because it makes no radical change in their inherited faith and practices of worship. And in stimulating resistance to Syria he is still the prophet of the old "God of the hosts of Israel"—a God who works deliverance by the thews and sinews of His earthly warriors. But Isaiah's ideal of religion was one which could never have been realized by a political movement; to root out all idols, all superstitions inconsistent with his lofty conception of the just King of Israel, who cares not for sacrifice and oblation, who can be acceptably approached through no religion of rote, whose sovereignty can receive practical recognition only by a thoroughgoing reformation of all parts of social life—this was an ideal which could not be carried out by the mere education and concentration of any forces inherent in the nation. The true Israel of Isaiah is not an historical possibility; it is a transcendental ideal for which he himself demands as a preliminary condition an outpouring of Jehovah's spirit on king (*Isa.* xi. 2) and people (*Isa.* xxxii. 15), working an entire moral regeneration. And so too it is not through the material organization of the Judæan kingdom that Isaiah looks for deliverance from Assyria. He sees with absolute clearness the powerlessness of the little realm against that great empire: the Assyrian must fall, and fall before Jerusalem, that Jehovah alone may appear to all the earth as the one true God, while all the idols appear as vain to help their worshippers; but he falls by no earthly sword, but before the direct interposition of Jehovah Himself. These conceptions break through the old particularistic idea of Jehovah and His religion at every point. Zion is now not the centre of a mere national cult, but the centre of all true religion for the whole world; and more than once the prophet indicates not obscurely that the necessary issue of the great conflict between Jehovah and the gods of the heathen must be the conversion of all nations, the disappearance of every other religion before the faith of the God of Israel. But this all-conquering religion is not the popular Jehovah worship; why then can the prophet still hold that the one true God is yet the God of Israel, and that the vindication of His Godhead involves the preservation of Israel? Not because His providence is confined to Israel—it embraces all nations; not because He shows any favouritism to Israel—He judges all nations by the same strict rule. If Israel alone among nations can meet the Assyrian with the boast "with us is God," the reason is that in Zion the true God is known<sup>3</sup>—not indeed to the mass, but to the prophet and to the "holy seed" which forms the salt of the nation. The interpretation which Isaiah puts

<sup>3</sup> We should be apt to say "the true idea of God," but that is a way of putting it which does not correspond with prophetic thought. To the prophet's knowledge of God is concrete knowledge of the divine character as shown in acts—knowledge of a person, not of an idea.

on this fact depends on the circumstance that at that date religion had never been conceived as a relation between God and individuals, or as a relation between God and a purely spiritual society, but always as a relation between a deity and some natural social group—a stock, a tribe, a nation. It was therefore only as the God of Israel that the true God could be known within Israel; and so on the one hand the little society of faith—which had not in reality the least tinge of political coherence—is thought of as yet forming the true kernel of the nation *qua* nation, while on the other hand the state of Judah profits by the prophetic religion inasmuch as the nation must be saved from destruction in order that the prophetic faith—which is still bound up with the idea of the nation—may not be dissolved. This connexion of ideas was not of course explicitly before the prophet's mind, for the distinctive features of a national religion could not be formulated so long as no other kind of religion had ever been heard of. When we put down in black and white the explicit details of what is involved in Isaiah's conclusion of faith we see that it has no absolute validity. True religion can exist without having a particular nation as its subject as soon as the idea of a spiritual community of faith has been realized. But till this idea was realized Isaiah was right in teaching that the law of continuity demanded that the nation within which Jehovah had made Himself known to His spiritual prophets must be maintained as a nation for the sake of the glory of God and the preservation of the "holy seed."

The catastrophe of Sennacherib's army, in which the doctrine of the inviolability of Zion received the most striking practical confirmation, was welcomed by Isaiah and his disciples as an earnest of the speedy inbringing of the new spiritual era. But these hopes were not fulfilled. The prophetic teaching had indeed produced a profound effect; to the party of reaction, as the persecution under Manasseh shows, it seemed to threaten to subvert all society; and we can still measure the range and depth of its influence in the literary remains of the period from Isaiah to the captivity, which include Micah vi. 1-8, and that noble essay to build a complete national code on the principle of love to God, righteousness, and humanity—the legislation of Deuteronomy. Nay more, the reception of the book of Deuteronomy by king and people in the eighteenth year of Josiah shows what a hold the prophetic teaching had on the popular conscience; it was no small triumph that there was even a passing attempt to introduce such a code as the law of the land. But it was one thing to touch the conscience of the nation and another to change its heart and renew its whole life. That no code could do, and, as every practical government must adapt itself to actualities and not to a purely ideal standard, it must have appeared at once that the attempt to govern by prophetic ideas was only sewing a new piece on an old garment. The immediate result of Josiah's reformation was the complete dissolution of anything that could be called a political party of prophetic ideas; the priests and the ordinary prophets were satisfied with what had been accomplished; the old abuses began again, but the nation had received a reformed constitution and there was nothing more to be said.

Thus it was that, though beyond question there had been a real advance in the average ethical and spiritual ideas of the people since the time of Isaiah, Jeremiah found himself more isolated than Isaiah had ever been. Even in that earliest part of his book which is mainly a recapitulation of his experiences and work in the reign of Josiah, his tone is one of absolute hopelessness as to the future of the nation. But we should quite misunderstand this pessimism if we held it to mean that Jeremiah saw

no signs of private morality and individual spiritual convictions among his people. To him as a prophet the question was whether Israel as a nation could be saved. In Isaiah's days the answer had been affirmative; there appeared to be at least a potentiality of national regeneration in the holy seed when once it should be cleansed from the chaff by a work of judgment. But, now a century of respite had been granted, the Chaldeans were at the gates, and there was no sign of valid national repentance. The harvest was past, the season of ripe fruits was over, and still Israel was not saved (Jer. viii. 20). The time of respite had been wasted, all attempts at national reformation had failed; how should Jehovah spare a nation which had shown no tokens of fitness to discharge the vocation of Jehovah's people? The question was not whether there was still a faithful remnant, but whether that remnant was able to save the state as a state, and this Jeremiah was forced to deny. Nay every attempt at genuine amendment was frustrated by the dead weight of a powerful opposition, and when the first captivity came it was precisely the best elements of Judah that went into captivity and were scattered among the nations (xxiv. 5; xxiii. 2 *sq.*). And so the prophet was compelled to teach that the immediate future of Israel was a blank, that the state as a state was doomed. He did not even dare to intercede for such a nation (vii. 16); though Moses and Samuel stood pleading for it before Jehovah, He could not but cast it out of His sight (xv. 1). It was the death-struggle of the idea of a national religion (vi. 8); the continuity of true faith refused to be longer bound up with the continuity of the nation. Still indeed the New-Testament idea of a purely spiritual kingdom of God, in this world but not of it, is beyond the prophet's horizon, and he can think of no other vindication of the divine purpose than that the true Israel shall be gathered again from its dispersion. But the condition of this restoration is now changed. To gather the dispersed implies a call of God to individuals, and in the restored Israel the covenant of Jehovah shall be not merely with the nation but with men one by one, and "they shall no more teach everyone his neighbour saying, Know the Lord, for all shall know Me from the least of them even to the greatest of them" (xxxiii. 33 *sq.*). In a word, when the nation is dissolved into its individual elements the continuity and ultimate victory of true faith depends on the relation of Jehovah to individual souls, out of which the new state shall be built up (Jer. iii. 14).

Thus, for the first time in the world's history, the ultimate problem of faith is based on the relation of God to the individual believer; and this problem Jeremiah is compelled to face mainly in relation to his own personality, to assure himself that his own faith is a true possession and lifts him above all the calamities that assail him, in spite of the hopeless ruin of his nation. The struggle is a sore one; his very life is bitter to him; and yet he emerges victorious. To know that God is with him is enough though all else fail him. Now as soon as the relation of God to a single soul has thus been set free from all earthly conditions the work of prophecy is really complete, for what God has done for one soul He can do for all, but only by speaking to each believer as directly as He does to Jeremiah. Henceforth revelation is not a word to the nation spoken through an individual, but a word spoken to one which is equally valid for every one who receives it with like faith. The New Testament joins on not to the post-exile prophets, who are only faint echoes of earlier seers, but to Jeremiah's great idea of the new covenant in which God's law is written on the individual heart, and the community of faith is the fellowship of all to whom He has thus spoken. The prophets of the restoration are

only the last waves beating on the shore after the storm which destroyed the old nation, but created in its room a fellowship of spiritual religion, had passed over; they resemble the old prophets in the same imperfect way in which the restored community of Jerusalem resembled a real nation. It was only in so far as the community of faith still possessed certain external features of nationality that post-exile prophecy was possible at all, and very soon the care of the national or quasi-national aspects of religion passed altogether out of their hands into those of the scribes, of whom Ezekiel was the first father, and whose Torah was not the living word of prophecy but the Pentateuchal code. From the time of Jeremiah downwards the perennial interest of Old-Testament thought lies in the working out of the problems of personal religion and of the idea of a spiritual fellowship of faith transcending all national limitation; and these are the motives not only of the lyrics of the Psalter but of the greater theodiceas of Isa. xl.-lxvi. and of the book of Job. The theodicea of the prophets is national; they see Jehovah's righteousness working itself out with unmistakable clearness in the present, and know that all that He brings upon Israel is manifestly just; but from the days of Jeremiah<sup>1</sup> the fortunes of Israel as a nation are no longer the one thing which religion has to explain; the greater question arises of a theory of the divine purpose which shall justify the ways of God with individual men or with His "righteous servant"—that is, with the ideal community of true faith as distinct from the natural Israel. The discussion of these problems constitutes a quite distinct type of Old-Testament literature beginning with the book of the Great Unknown, which is now appended to the writings of Isaiah; but this is an accident of arrangement that ought not to lead us to include among the prophetic writings proper a work so entirely different in origin and scope, and addressed not to an actual nation but to the ideal Israel, whose vocation is no longer political but purely religious.

It will be evident even from this rapid sketch, necessarily confined to a few of the most cardinal points, that Hebrew prophecy is not a thing that can be defined and reduced to a formula, but was a living institution which can only be understood by studying its growth and observing its connexion with the historical movements with which its various manifestations were bound up. Throughout the great age of prophecy the most obvious formal character that distinguished it was that the prophet did not speak in his own name but in the name of Jehovah. But the claim to speak in the name of God is one which has often been made—and made sincerely—by others than the prophets of Israel, and which is susceptible of a great variety of meanings, according to the idea of God and His relation to man which is presupposed. Every early religion seeks to realize such an intercourse with the object of worship as shall be two-sided; when the worshipper approaches the deity he desires to have an answer assuring him of acceptance and divine aid. The revelation thus looked for may be found in natural omens, in the priestly lot or some similar sacral oracle, or, finally, in the words of a seer who is held to be in closer contact with the deity than common men. Broadly speaking these methods of revelation are found in all ancient religions, but no other religion presents anything precisely analogous to prophecy. It is true that the prophets absorbed the old seers, and that the Israelites, as we see in the case of the asses of Kish, went to their seers on the same kind of occasions as sent heathen nations to seers or diviners. There is sufficient evidence that down to the last age of the Judean monarchy practices not essentially different from divination were current in all classes of

society, and were often in the hands of men who claimed to speak as prophets in the name of Jehovah. But the great prophets disallowed this claim, and the distinction which they draw between true prophecy and divination is recognized not only in the prophetic law of Deuteronomy but in earlier parts of the Pentateuch and historical books. "There is no augury in Jacob and no divination in Israel; in due time it is told to Jacob and to Israel what God doth work" (Num. xxiii. 23). The seer, in the sense in which all antiquity believed in seers, is simply a man who sees what others cannot see, no matter whether the thing seen be of public or of mere private interest; but the prophet is an organ of Jehovah's kingship over His people—he sees and tells so much of the secret purpose of Jehovah as is needful for His people to know. We have already seen how Amos and Hosea put this (*supra*, p. 817), and it does not appear that they were introducing a conception of prophecy formally novel—the new thing was their conception of Jehovah's purpose. And so too with the following great prophets; the important thing in their work was not their moral earnestness and not their specific predictions of future events, but the clearness of spiritual insight with which they read the spiritual significance of the signs of the time and interpreted the movements of history as proofs of Jehovah's actual moral sovereignty exercised over Israel. So long as the great problems of religion could be envisaged as problems of the relation of Jehovah to Israel as a nation the prophets continued to speak and to bring forth new truths; but the ultimate result was that it became apparent that the idea of moral government involved the destruction of Israel, and then the function of prophecy was gone because it was essentially national in its objects. But meantime the relation of God to the prophet had acquired an independent significance; the inner life of Isaiah during the long years when his teaching seemed lost, or of Jeremiah through the whole course of his seemingly fruitless ministry, was rich in experiences of faith triumphing over temptations and trials, of personal converse with God sustaining the soul in the face of difficulties hopeless to the eye of sense, which formed the pattern of a new and higher stage of religion in which the relation of the individual soul to God should be set free from those limitations which had been imposed by the conception that the primary subject of religion is the nation. But the religion of the Old Testament did not become merely individualistic in becoming individual, and now the problem was to realize a new conception of the society of faith, the true Israel, the collective servant of Jehovah—in a word to form the idea of a spiritual commonwealth and to show how it was possible for faith to hold fast, in spite of all seeming contradiction, to the truth that Jehovah had chosen for Himself a spiritual people, every member of which was in truth the object of His saving and unfailing love, and which should ultimately in very deed inherit that glory of which the carnal Israel was unworthy. This is the post-prophetic problem which occupies the more profound of the later Old-Testament books, but first received its true solution in the gospel, when the last shreds of the old nationalism disappeared and the spiritual kingdom found its centre in the person of Christ.

Old-Testament prophecy therefore forms only one stage in a larger development, and its true significance and value can only be realized when it is looked at in this light. In this as in all other matters of transcendental truth "wisdom is justified of her children"; the conclusive vindication of the prophets as true messengers of God is that their work forms an integral part in the progress of spiritual religion, and there are many things in their teaching the profundity and importance of which are

<sup>1</sup> One might say from the days of Habakkuk.

The prophets themselves required no historical verification of their word to assure them that it was indeed the word of God, nor do they for a moment admit that their contemporaries are entitled to treat its authority as unproved till such verification is offered. The word of God carries its own evidence with it in its searching force and fire: "Is not my word like as a fire, saith Jehovah, and like a hammer that breaketh the rock in pieces?" (Jer. xxiii. 29). To the prophet himself it comes with imperious force: it constrains him to speak (Amos iii. 8), seizes him with a strong hand (Isa. viii. 11), burns like a fire within his bones till it finds utterance (Jer. xx. 9); and it is this force of moral conviction which ought also to commend it to the conscience of his hearers. The word is true because it is worthy of the true God. When Dent. xviii. 21, 22 seeks the legal criterion of true prophecy in the fulfilment of prediction, the writer is no doubt guided by the remembrance of the remarkable confirmation which the doctrines of spiritual prophecy had received in history

*Literature*.—In the ancient and medieval church and in the dominant part of Protestantism there was little or no attempt at the realization of prophecy, and the prophecies by which were found in nature only through the spiritual of a spiritual or mystical exercise. For details the reader may refer to Bunsen, *Quintessence des Altes Testament*, Bonn, 1873, and for the final form of orthodox Protestantism to V. W. W., *De Prophetis et Propetia*. The growing sense of the insufficiency of an instrument towards the development of the prophetic domain is well illustrated in the 19th century. On the other hand we have the revival of scientific exercise by Comenius and his school, which has continued to influence certain circles down to the present day, and has led to a more varied attempt to find in prophetic literature, written before the critical and scientific transformations of the Christian church down to the end of the 18th century. On the other hand Lavater's *Lectures on Hebrew Poetry*, and the more extensive *Prophecy of Isaiah* (1776), show the beginnings of a tendency to look mainly at the moral and religious aspects of the prophetic books, and to view a prophetic as a moral and religious process. This tendency continued in Ewald's *De Prophetis et Propetia*, 1815. Neither of these methods could do justice for the historical and critical study of the phenomena of prophecy as a whole, and the more liberal treatment of the Old Testament was first founded by the moral and historical rationalism which was successful in the 19th century. The first results of real progress, and of a more profound had been taken through, was to get a living conception of the prophet in whom the prophecies were uttered, and this again called for a revision of all traditional notions as to the nature of the various parts of Hebrew Literature. One aim of the progress of the science, and one which the prophetic books themselves testify to the first place. In recent times there has been a advance in the understanding of the prophets has turned on part pairs with the literary criticism, especially the criticism of the Pentateuch, and with the general study of Hebrew history; and more works on the subject have to Ewald must be regarded as quite as quoted except for the literary criticism on details points of exegesis. One of the progress and the works in general the best book is still Ewald's *Propetia des Altes Testaments* (1841, 2d ed. 1875, Eng. tr. 1876-77). The second is treated in all ways as Old Testament literature, as a literature which Ewald's *Quintessence des Altes Testaments* the 2nd place, and on Old Testament as the 3rd (see especially V. W. W., *Religion des A. T.*, 1876). On the treatment of the prophecies there is a separate work by Dahn, Bonn, 1873, and Ewald's *Propetia des Altes Testaments*, 1875, is a separate introduction of the prophetic books. Ewald's *Propetia des Altes Testaments* and *Propetia des Altes Testaments*.

<sup>2</sup> See 5 Kings xxiii. 21, and also Deut. xxxiv. 6. So too all the old national heroes and heroines ultimately became prophets; in the case of Deborah there is even a fusion in local tradition between an old heroine and an historical seer.

(1875, Eng. tr. 1877) is in form mainly a criticism of the traditional view of prophecy, and should therefore be compared with his *Onderzoek en Godsdiens van Israel*. Most English books on the subject are more theological than historical, but a sketch of Hebrew prophecy in connexion with the history down to the close of the 8th century is given by W. R. Smith, *The Prophets of Israel*, Edinburgh, 1892. A useful commentary on the prophetic books in general forms two volumes of Reuss, *La Bible* (Paris, 1876); the special literature is referred to in the articles on the several prophets. The literature of the theological questions connected with prophecy is much too copious to be cited here; lists will be found in several of the books already referred to. (W. R. S.)

2. *Prophets in the Christian Church.*—The appearance of prophets in the first Christian communities is one proof of the strength of faith and hope by which these bodies were animated. An old prophecy (Joel iii. 1) had foretold that in the Messianic age the spirit of God would be poured out on every member of the religious community, and in point of fact it was the universal conviction of those who believed in Christ that they all possessed the Spirit of God. This Spirit, manifesting His presence in a variety of ways and through a variety of gifts, was to be the only ruling authority in the church. He raised up for Himself particular individuals, into whose mouths He put the word of God, and these were at first regarded as the true leaders of the congregations. We find accordingly that there were prophets in the oldest church, that of Jerusalem (Acts xi. 27; xv. 32), and again that there were "prophets and teachers" in the church at Antioch (Acts xiii. 1). These were not office-bearers chosen by the congregation, but preachers raised up by the Spirit and conferred as gifts on the church. When Paul says (1 Cor. xii. 28; cf. Eph. iv. 11), "God has set some in the church, first as apostles, second as prophets, third as teachers," he points to a state of things which in his time prevailed in all the churches both of Jewish and heathen origin. We here learn from Paul that the prophets occupied the second position in point of dignity; and we see from another passage (1 Cor. xiv.) that they were distinguished from the teachers by their speaking under the influence of inspiration,—not, however, like the "speakers in tongues," in unintelligible ejaculations and disconnected words, but in articulate, rational, edifying speech. Until recently it was impossible to form any distinct idea of the Christian prophets in the post-apostolic age, not so much from want of materials as because what evidence existed was not sufficiently clear and connected. It was understood, indeed, that they had maintained their place in the churches till the end of the 2d century, and that the great conflict with what is known as Montanism had first proved fatal to them; but a clear conception of their position and influence in the churches was not to be had. But the discovery, by Bryennios, of the ancient Christian work called *Διδαχὴ τῶν δώδεκα ἀποστόλων* has immensely extended the range of our knowledge, and has at the same time thrown a clear light on many notices in other sources which for want of proper interpretation had been previously neglected or incorrectly understood.

The most important facts known at present about the manner of life, the influence, and the history of the early Christian prophets are the following. (1) Down to the close of the 2d century the prophets (or prophetesses) were regarded as an essential element in a church possessing the Holy Ghost. Their existence was believed in, and they did actually exist, not only in the catholic congregations—if the expression may be used—but also in the Marcionite church and the Gnostic societies. Not a few Christian prophets are known to us by name; as Agabus, Judas, and Silas in Jerusalem; Barnabas, Simon Niger, &c., in Antioch; in Asia Minor, the daughters of Philip, Quadratus, Ammia, Polycarp, Melito, Montanus, Maximilla, and Priscilla; in Rome, Hermas; among the followers of Basilides, Barkabbas and Barkoph; in the community of Apelles, Philumene, &c. Lucian tells us that the impostor Peregrinus Proteus, in the time of Antoninus Pius,

figured as a prophet in the Christian churches of Syria. (2) Till the middle of the 2d century the prophets were the regular preachers of the churches, without being attached to any particular congregation. While the "apostles" (i.e., itinerating missionaries) were obliged to preach from place to place, the prophets were at liberty either, like the teachers, to settle in a certain church or to travel from one to another. (3) In the time of Paul the form of prophecy was reasoned exhortation in a state of inspiration; but very frequently the inspiration took the form of ecstasy—the prophet lost control of himself, so that he did not remember afterwards what he had said. In the Gentile-Christian churches, under the influence of pagan associations, ecstasy was the rule. (4) With regard to the matter of prophecy, it might embrace anything that was necessary or for the edification of the church. The prophets not only consoled and exhorted by the recital of what God had done and predictions of the future, but they uttered extempore thanksgivings in the congregational assemblies, and delivered special directions, which might extend to the most minute details, as, for example, the disposal of the church funds. (5) It was the duty of the prophets to follow in all respects the example of the Lord (*ἔχειν τοὺς τρόπους τοῦ Κυρίου*), and to put in practice what they preached. But an ascetic life was expected of them only when, like the apostles, they went about as missionaries, in which case the rules in Mat. x. applied to them. Whenever, on the contrary, they settled in a place they had a claim to a liberal maintenance at the hands of the congregation. The author of the *Διδαχὴ* even compares them to the high priests of the Old Testament, and considers them entitled to the first-fruits of the Levitical law. In reality, they might justly be compared to the priests in so far as they were the mouthpieces of the congregation in public thanksgiving. (6) Since prophets were regarded as a gift of God and as moved by the Holy Spirit, the individual congregation had no right of control over them. When anyone was approved as a prophet and exhibited the "conversation of the Lord," no one was permitted to put him to the test or to criticize him. The author of the *Διδαχὴ* goes so far as to assert that whoever does this is guilty of the sin against the Holy Ghost. (7) This unique position of the prophets could only be maintained so long as the original enthusiasm remained fresh and vigorous. From three quarters primitive Christian prophecy was exposed to danger,—first, from the permanent officials of the congregation, who, in the interests of order, peace, and security could not but look with suspicion on the activity of excited prophets; second, from the prophets themselves, in so far as an increasing number of dishonest characters was found amongst them, whose object was to levy contributions on the churches;<sup>1</sup> third, from those prophets who were filled with the stern spirit of primitive Christianity and imposed on churches, now becoming assimilated to the world, obligations which these were neither able nor willing to fulfil. It is from this point of view that we must seek to understand the so-called Montanistic crisis. Even the author of the *Διδαχὴ* finds it necessary to defend the prophets who practised celibacy and strict asceticism against the depreciatory criticism of church members. In Asia Minor there was already in the year 160 a party, called by Epiphanius "Alogi," who rejected all Christian prophecy. On the other hand, it was also in Asia Minor that there appeared along with Montanus those energetic prophetesses who charged the churches and their bishops and deacons with becoming secularized, and endeavoured to prevent Chris-

<sup>1</sup> See Lucian's story about Peregrinus, and that chapter of the *Διδαχὴ* where the author labours to establish criteria for distinguishing false prophets from true.

tianity from being naturalized in the world, and to bring the churches once more under the exclusive guidance of the Spirit and His charismata. The critical situation thus arising spread in the course of a few decades over most of the provincial churches. The necessity of resisting the inexorable demands of the prophets led to the introduction of new rules for distinguishing true and false prophets. No prophet, it was declared, could speak in ecstasy,—that was devilish; further, only false prophets accepted gifts. Both canons were innovations, designed to strike a fatal blow at prophecy and the church organization re-established by the prophets in Asia,—the bishops not being quite prepared to declare boldly that the church had no further need of prophets. But the prophets would not have been suppressed by their new methods of judging them alone. A much more important circumstance was the rise of a new theory, according to which all divine revelations were summed up in the apostles or in their writings. It was now taught that prophecy in general was a peculiarity of the Old Testament ("lex et prophetæ usque ad Johannem"); that in the new covenant God had spoken only through apostles; that the whole word of God so far as binding on the church was contained in the apostolic record—the New Testament;<sup>1</sup> and that, consequently, the church neither required nor could acknowledge new revelations, or even instructions, through prophets. The revolution which this theory gradually brought about is shown in the transformation of the religious, enthusiastic organization of the church into a legal and political constitution. A great many things had to be sacrificed to this, and amongst others the old prophets. The strictly enforced episcopal constitution, the creation of a clerical order, and the formation of the New Testament canon accomplished the overthrow of the prophets. Instead of the old formula, "God continually confers on the church apostles, prophets, and teachers," the word now was—"The church is founded in the (written) word of the prophets (i.e., the Old-Testament prophets) and the apostles (viz., the twelve and Paul)."<sup>2</sup> After the beginning of the 3d century there were still no doubt men under the control of the hierarchy who experienced the prophetic ecstasy, or clerics like Cyprian who professed to have received special directions from God; but prophets by vocation no longer existed, and these sporadic utterances were in no sense placed on a level with the contents of the sacred Scriptures.

See Bückmann, "Ueber die Wunderkräfte bei den ersten Christen und ihr Erlöschen," in the *Ztschr. f. d. ges. luther. Theol. u. Kirche*, 1878, p. 216–255 (learned but utterly uncritical); Bonwetsch, "Die Prophetie im apostol. und nachapostol. Zeitalter," in the *Ztschr. f. kirchl. Wissensch. u. kirchl. Leben*, 1884, part 8, p. 405 sq., part 9, p. 460 sq.; Harnack, *Die Lehre der zwölf Apostel*, 1884, p. 93–137.

(A. H. A.)

PROSELYTE (προσelytos) is the term most frequently adopted by the Septuagint, especially in legal passages, to represent the Hebrew גֵּר. The *gēr*, or more fully *gēr w'tōshāb*, is not any "stranger" but a stranger dwelling in a Hebrew community and enjoying a certain measure of protection. In old time at least the position of such a stranger was no doubt very insecure, for he had no strong kinsmen to take his part, and so, like the widow and orphan, with whom many passages of the Old Testament associate him, he was liable to oppression. The law as well as the prophets commend him to the humane regard of his neighbours, but it would have been quite foreign to antique ideas to grant him equal rights (see Lev. xxv. 45; Deut. xxiii. 20). Like the Arabic *jār*, therefore (whose name is at bottom the same), he must have generally sought to attach himself as a client to some individual or community able to protect him, and so we must

understand the metaphor in passages like Ps. xv. 1, xxxix. 12.

In the old Hebrew kingdom the word *gēr* had a civil not a religious significance, and it would almost seem that a poor Israelite without inheritance might sink to this position, which indeed is scarcely distinguishable from that of the Levite in Jud. xvii. 8, who went forth to sojourn (*gūr*) where he might find a place. The exile and the restoration made a change in this as in all other aspects of Hebrew society. On the one hand Ezekiel xlvii. 22 and Isa. xiv. 1 contemplate that the restored nation shall be recruited by strangers who are received on equal terms; but, as the Jews returned not as an independent nation but as a distinct religious community, this implies especially that the sons of the stranger, by joining Israel, observing the Sabbath, and holding fast to Jehovah's covenant, may gain admission to all the privileges of the temple and its worship. So it is put in Isa. lvi. 6, 7 in marked contrast to the restrictions laid down in Deut. xxiii. 3, 7 sq. That the views of the prophets had practical issue cannot be doubted; even the foreign Nethinim in the second temple were rapidly transformed not merely into good Israelites but into Levites. The condition of admission to the full privileges of an Israelite, in particular to the passover, is, according to the Priestly Code (Exod. xii. 48; Numb. ix. 14), circumcision,—to which the later Jewish usage adds lustration by immersion in water (baptism, *ḥ'ālā*) and the presentation of a sacrifice (*korban*). The immersion, about which there has been a good deal of controversy, some maintaining that it came into use later than Christian baptism, was really a necessary act for one who had been previously unclean, and may be held to be involved in the general Pentateuchal law of ceremonial washings. The later technical name for a heathen who thus joined the theocracy was גֵּר צַדִּיק, "proselyte of righteousness."

The free admission of foreigners to the Jewish church is a mark of the universalistic tendency which, in spite of all the narrownesses of Judaism under the law, accompanied the break-up of the old national system. On the other hand the so-called Law of Holiness (later than Ezekiel but earlier than the Priestly Code), which is contained in Lev. xvii. sq., presents a different line of transition from the purely civil to the religious meaning of *gēr*. In these laws, which proceed throughout on the principle that Israel, and all that has to do with Israel, must be regulated by regard to formal holiness, it is demanded that certain rules shall be enforced not only on Israelites proper but on strangers sojourning in their land. They are not to eat blood (xvii. 10), commit incest (xviii. 26), sacrifice to Moloch (xx. 2), or blaspheme Jehovah (xxiv. 16); and for murder and other crimes they are to be answerable to the Hebrew authorities according to Hebrew law (xxiv. 22). These rules are in substance—the third being extended to a prohibition of idolatry generally—the "Noachic laws" to which in later usage a man or woman might promise to conform and thereby, without becoming a regular member of the theocracy, be recognized as a "proselyte of the gate," i.e., "within the gates of Israel." What the Law of Holiness proposed to enforce became in fact—the theocracy not possessing political power over strangers—a voluntary obligation assumed by those "who worshipped God" (σεβόμενοι τὸν θεόν, Acts xiii. 50, xvi. 14, xvii. 4, 17, xviii. 7—in E.V. often rendered "devout").

The proselytizing zeal of the Jews is spoken of in Mat. xxiii. 15, and by many Greek and Latin writers. Up to the time of Hadrian it was facilitated by the favour generally extended to the Jews by the Roman emperors; and not only on Semitic soil, as at Damascus, where Josephus tells us that most of the women were proselytes, but

<sup>1</sup> The Apocalypse of John was received into it, not as the work of a prophet, but as that of an apostle.

throughout the Roman world many converts were made, especially among women. The most noted conversion was that of the royal house of Adiabene (Josephus, *Ant.*, xx, 2), of which the splendid tomb of Queen Helena, a little way outside of Jerusalem, still remains a monument.

PROSERPINE (*Proserpina*) is the Latin form of PERSEPHONE,<sup>1</sup> a Greek goddess, daughter of Zeus and the earth-goddess Demeter. In Greek mythology Demeter and Proserpine were closely associated, being known together as the two goddesses, the venerable or august goddesses, sometimes as the great goddesses. Proserpine herself was commonly known as the daughter (Core), sometimes as the first-born. As she was gathering flowers with her playmates in a meadow, the earth opened and Pluto, god of the dead, appeared and carried her off to be his queen in the world below. This legend was localized in various places, as at Eleusis, Lerna, and "that fair field of Enna" in Sicily. Torch in hand, her sorrowing mother sought her through the wide world, and finding her not she forbade the earth to put forth its increase. So all that year not a blade of corn grew on the earth, and men would have died of hunger if Zeus had not persuaded Pluto to let Proserpine go. But before he let her go Pluto made her eat the seed of a pomegranate, and thus she could not stay away from him for ever.<sup>2</sup> So it was arranged that she should spend two-thirds (according to later authors, one-half) of every year with her mother and the heavenly gods, and should pass the rest of the year with Pluto beneath the earth. There can be little doubt that this is a mythological expression for the growth of vegetation in spring and its disappearance in autumn. According to Theopompus there was a Western people who actually called the spring Proserpine. As wife of Pluto, she sent spectres, ruled the ghosts, and carried into effect the curses of men. The lake of Avernus, as an entrance to the infernal regions, was sacred to her. From the head of a dying person Proserpine was supposed to cut a lock of hair which had been kept sacred and unshorn through life.<sup>3</sup> She was sometimes identified with Hecate. On the other hand in her character of goddess of the spring she was honoured with flower-festivals in Sicily and at

Hipponium in Italy. Sicily was a favourite haunt of the two goddesses, and ancient tradition affirmed that the whole island was sacred to them. The Sicilians claimed to be the first on whom Demeter had bestowed the gift of corn, and hence they honoured the two goddesses with many festivals. They celebrated the festival of Demeter when the corn began to shoot, and the descent of Proserpine when it was ripe. At Cyare, a fountain near Syracuse which Pluto made to spring up when he carried off his bride, the Syracusians held an annual festival in the course of which bulls were sacrificed by being drowned in the water. At Cyzicus also, in Asia Minor, bulls were sacrificed to Proserpine. Demeter and Proserpine were worshipped together by the Athenians at the greater and less Eleusinian festivals, held in autumn and spring respectively. In the Eleusinian mysteries Proserpine no doubt played an important part (see ELEUSINIA and MYSTERIES). One Greek writer, Achemachus, identified Proserpine with the Egyptian Isis. At Rome Proserpine was associated with Ceres (the Roman representative of Demeter) in the festival of the Cerealia (April 12 to 19), she was represented as the wife of Dis Pater (the Roman Pluto), and was sometimes identified with the native Latin goddess Libera. The pomegranate was Proserpine's symbol, and the pigeon and cock were sacred to her. Her votaries abstained from the flesh of domestic fowls, fish, beans, pomegranates, and apples. In works of art she appears with a cornucopia or with ears of corn and a cock. The regular form of her name in Greek was Persephone, but various other forms occur—Phersephone, Persephassa, Phersephassa, Pherrephatta, &c., to explain which different etymologies were invented. Corresponding to Proserpine as goddess of the dead is the old Norse goddess *Hel* (Gothic *Halja*), whom Saxo Grammaticus calls Proserpine. (J. G. FR.)

PROSKUROFF, a district town of the government of Podolia, Russia, situated on the railway from Odessa to Lemberg, 62 miles to the north-west of Schmerinka junction, and on the highway from Zhitomir to Kieff. It is poorly built, mostly of wood, on a low marshy plain surrounded by hills, at the junction of the Ploskaya with the Bug. Its old castle has been destroyed, the site being occupied by a Catholic church. The Orthodox cathedral (1839) contains a very ancient and highly venerated icon of the Virgin. The manufactures are insignificant; but the Jewish merchants carry on an active export trade in corn and sugar, while the imports consist of salt and various manufactured wares. Agriculture and market-gardening are the chief occupations of its Little-Russian inhabitants. Of the population (11,750 in 1880) more than one-half are Jews.

PROSPER OF AQUITAINE (AQUITANUS, or AQUITANICUS), a Christian prose and verse writer of the first half of the 5th century. Of his personal history almost nothing is known; his surname seems to imply that he was a native of Aquitania, and there are various indications that he was educated as a "rhetorician." While still comparatively young he gave himself to a religious and ascetic life, and at Marseilles soon made himself prominent as a champion of orthodoxy in the controversy with the Massilians or Semi-Pelagians. In this connexion he opened a correspondence with Augustine, along with his friend Hilarius (c. 429 A.D.), and about the same time (c. 430) he composed an hexameter poem of upwards of one thousand lines, *Adversus Ingratos*, a glowing polemic against the Pelagians. After Augustine's death he wrote *Pro Augustino Responsiones*, and about 431 he visited Rome, still in the interests of Augustinianism, eliciting from Pope Celestine his *Epistola ad Episcopos Gallorum* against Cassianus. There are some indications that the latter years of his life

<sup>1</sup> Some, however, regard *Proserpina* as a native Latin form, not borrowed from the Greek.

<sup>2</sup> The idea that persons who have made their way to the abode of the dead can return to the upper world if they have not tasted the food of the dead appears elsewhere, as in New Zealand (R. Taylor, *New Zealand*, pp. 233, 271).

<sup>3</sup> *Æn.*, iv. 698 sq. It appears to have been a Greek custom to cut a lock of hair from a dead man's head, and hang it outside of the house door, in token that there was a corpse in the house. At least this seems a fair inference from Eurip., *Alc.*, 75, 76, 101-4. The lock so cut may have been that which was kept sacred to the gods and unshorn (*Elym. Mag.*, s.v., ἀπεσκολυμμένος). For examples of hair dedicated to gods, see *Il.*, xxiii. 141 sq.; *Plut.*, *Thes.*, 5; *Paus.*, viii. 20, 3. In Tibet a lama (priest) is called in to cut off some hairs from the head of a dying person, in order that his soul may escape through the top of his head, which is deemed an essential condition of a good transmigration (Horace de la Penne, in Bogle and Manning's *Travels in Tibet*). We can hardly doubt that the intention of the Græco-Roman custom was similar. In modern Greece the god of death, Charos, is supposed to draw the soul out of the body, and if a man resists the Arachobites believe that Charos slits open his breast (*B. Schmidt, Volksleben der Neugriechen*, p. 228). There are other instances of incisions made in the body of a dying person to allow his soul to escape (cp. Bastian, *Mensch*, ii. 342). The custom probably dates from the times when death in battle was the usual death. In the legend of Nisus and Scylla there is a trace of the custom which was still observed in classical times in the sacrifice of animals. The practice of cutting off the hair of the dead prevailed in India, though it does not appear in the Vedas (Monier Williams, *Religious Thought and Life in India*, p. 281). We are reminded of the practice of the Pawnees and other North American Indians, who shaved the head with the exception of one lock (the scalp-lock), which was removed by a victorious enemy (Catlin, *North American Indians*, vol. ii. p. 24). The Sandwich Islanders also cut a lock from a slain foe (*Ellis, Pol. Res.*, vol. iv. p. 159).

were spent in Rome, and that he wrote his *Chronicon* there. The year of his death is unknown; the chronicle is brought down to 455.

Prosper's enthusiastic admiration for Augustine (to whom, however, he was not personally known) led him to make an abridgment of that author's commentary on the Psalms, as well as a collection of sentences for his works,—probably the first dogmatic compilation of the class in which the *Liber Sententiarum* is the best known example. Some of Augustine's theological dicta he also put into elegiac metre (one hundred and six epigrams). Prosper's *Chronicon* is of value from the year 29 A.D. onwards, some of the sources which he used for that period being no longer extant. The best edition of the *Opera* is the Benedictine by Le Brun and Mangeant (Paris, 1711), reprinted in Migne's collection.

PROSSNITZ (Slavonic, *Prostějov*), the chief place in the fertile district of the Hanna, in Moravia, Austria, is situated on the small river Rumza, 11 miles south-west of Olmütz. It carries on manufactures of sugar, cotton, and linen, and is an important centre for the sale of the barley and other produce of the Hanna. It is a town of ancient origin, and in the 16th century was one of the chief seats of the Moravian Brethren. Population in 1880, 16,751.

PROTAGORAS of Abdera, the first of the so-called Sophists,—who, about the middle of the 5th century B.C., asserted throughout Greece the claims of education or culture in opposition on the one hand to technical instruction and on the other to physical research,—was an older contemporary of Socrates. At the age of seventy, having been accused and convicted of atheism, Protagoras fled from Athens, and on his way to Sicily was lost at sea. His birth has been plausibly assigned to 481 and his death to 411 B.C. Forty years of his life were spent in the exercise of his popular and lucrative profession in the principal cities of Greece and Sicily. According to Plato (*Prot.*, 318 E), he endeavoured to communicate to his pupils "good counsel or prudence (*εὐβουλία*), which should fit them to manage their households, and to take part by word and deed in civic affairs." In short, he professed not to "instruct" but to "educate." Further, the education which he provided was of a literary sort,—oratory, grammar, style, and the interpretation of the poets being among the subjects which he used as instruments. His formal lectures were supplemented by discussions amongst his pupils. He left behind him several treatises, of which only two or three sentences have survived. In *Truth*, by way of justifying his rejection of philosophy or science, he maintained that "man is the measure of all things—of what is, that it is, and of what is not, that it is not."<sup>1</sup> Besides *Truth*, and the book *Of the Gods* which caused his condemnation at Athens, Diogenes Laertius attributes to him treatises on political, ethical, educational, and rhetorical subjects.

On the significance of the Sophistical movement, and the part which Protagoras took in promoting it, as well as for bibliographical information, see SOPHISTS.

PROTECTION. See FREE TRADE and POLITICAL ECONOMY.

PROTESTANTENVEREIN is the name of a society in Germany the general object of which is to promote the union and the progress of the various established Protestant churches of the country in harmony with the advance of culture and on the basis of Christianity. It was founded at Frankfort-on-the-Main in 1863 by a number of distinguished clergymen and laymen of liberal tendencies, representing the freer parties of the Lutheran and Reformed churches of the various German states, amongst whom were the statesmen Bluntsehli and Von Bennigsen and the professors Rothe, Ewald, Schenkel, Hilgenfeld, and Hitzig. The more special objects of the

association are the following:—the development of the churches on the basis of a representative parochial and synodal system of government in which the laity shall enjoy their full rights; the promotion of a federation of all the churches in one national church; resistance to all hierarchical tendencies both within and without the Protestant churches; the promotion of Christian toleration and mutual respect amongst the various confessions; the rousing and nurture of the Christian life and of all Christian works necessary for the moral strength and prosperity of the nation. These objects include opposition to the claims of Rome and to autocratic interference with the church on the part of either political or ecclesiastical authorities, efforts to induce the laity to claim and exercise their privileges as members of the church, the assertion of the right of the clergy, laity, and both lay and clerical professors to search for and proclaim freely the truth in independence of the creeds and the letter of Scripture. When the association was first formed the necessity for it was felt to be great. The separation between the Calvinistic and the Lutheran churches on the one hand, and between the churches of the various states on the other, even when the former separation had been bridged over by the Prussian Union; the entire absence of any satisfactory system of church government, the autocratic authority of either the monarch or his ministers, or of the clergy, being supreme; the increasing encroachments of the papal power upon the rights of the individual and the state; the growing estrangement of the educated classes from the church on the one hand, with the manifestation of either ignorance of the fact or a determination to meet it with bitter denunciation on the part of the orthodox clergy on the other, were regarded as urgent calls to action by the liberals. Membership in the association is open to all Germans who are Protestants and declare their willingness to cooperate in promoting its objects. To facilitate its operations, the general association is broken up into a few groups or societies confined to certain geographical areas. Every second year (at first every year) general meetings of the entire association are held at some convenient place. At first the governing committee had its permanent seat at Heidelberg, but in 1874 Berlin, as the new capital of the empire, was chosen. The means used to promote the objects aimed at are mainly (1) the formation of local branch associations throughout the country, the duty of which is by lectures, meetings, and the distribution of suitable literature to make known and advocate its principles, and (2) the holding of great annual or biennial meetings of the whole association, at which its objects and principles are expounded and applied to the circumstances of the church at the moment. The "theses" accepted by the general meetings of the association as the result of the discussions on the papers read indicate the theological position of its members. The following may serve as illustrations:—

The creeds of the Protestant church shut the doors on the past only, but open them for advance in the future; it is immoral and contrary to true Protestantism to require subscription to them. The limits of the freedom of teaching are not prescribed by the letter of Scripture, but a fundamental requirement of Protestantism is free inquiry in and about the Scriptures. The attempt to limit the freedom of theological inquiry and teaching in the universities is a violation of the vital principle of Protestantism. Only such conceptions of the person of Jesus can satisfy the religious necessities of this age as fully recognize the idea of his humanity and place in history. The higher reason only has unconditional authority, and the Bible must justify itself before its tribunal; we find the history of divine revelation and its fulfilment in the Bible alone, and reason bids us regard the Bible as the only authority and canon in matters of religious belief.

The formation of the association at once provoked fierce and determined opposition on the part of the orthodox sections of the church, particularly in Berlin. Attempts

<sup>1</sup> The exposition of this maxim contained in Plato's *Theætetus*, 152 C 2., is plainly not to be ascribed to Protagoras.

more or less successful have been made from the first to exclude clergymen and professors identified with it from the pulpits and chairs of Berlin and elsewhere, though membership in it involves no legal disqualification for either. One of the objects of the association was to some extent obtained by the reorganization of the Prussian Church when Dr Falk was cultus minister, on the basis of parochial and synodal representation, which came into full operation in 1879. But the election for the general synod turned out very unfavourable to the liberal party, and the large orthodox majority endeavoured to use their power against the principles and the members of the association. The members of the association elected to the general synod were nine only, while the party of the decidedly orthodox numbered upwards of seventy. In 1882 the position of the association was rendered still more difficult by the agitation in Berlin of Dr Kalthoff and other members of it in favour of a "people's church" on purely dissenting and extremely advanced theological principles. The turn of the political tide in the direction of conservatism in Berlin indicated by the retirement of the cultus minister Dr Falk increased the difficulties and the work of the association, far as Dr Falk was from sanctioning its theological principles. Moreover, it had sustained severe losses in its membership by death and other causes.

At the end of the twelfth year of its existence (1877) the association had 7500 members, its annual income was nearly £350, and it had distributed in the same year 10,000 copies of its publications. In 1880 the number of members had risen to 26,000, and of local associations to 80.

See Schenkel, *Der Deutsche Protestantenverein und seine Bedeutung für die Gegenwart* (Wiesbaden, 1868, 2d ed. 1871); *Der Deutsche Protestantenverein in seinen Statuten und den Thesen seiner Hauptversammlungen, 1865-82* (Berlin, 1883), and the annual reports in the *Allgemeine Kirchliche Kronik*, 1865-82, and *Theological Review*, July 1869, pp. 289-96.

PROTESTANTS is the generic term for members of the churches which owe their origin directly or indirectly to the REFORMATION (*q.v.*). The name is derived from the Protest of Spires in 1529 (see LUTHER, vol. xv. p. 80). Certain small communities of Christians older than the Reformation, but agreeing with it in rejecting the authority of Rome, are generally and quite logically grouped as Protestants; and popularly the name is considered to include all Christians who do not belong to the Greek and Roman Catholic communions, though members of the Anglican Church, for example, frequently protest against such a classification as historically false and personally obnoxious. Protestantism has flourished best among the Teutonic peoples of Northern Europe, and has always found it difficult to make its way among the Latin peoples of the South.

The following table shows approximately the number of Protestants in the world:—

#### I. EUROPE—

Great Britain and Ireland (Anglicans, 18,800,000; Presbyterians, 3,900,000; Methodists, 3,500,000; Independents, 1,200,000; Baptists, 1,000,000) .....	28,400,000 (estimate)
German Empire (Lutherans, Reformed, and United, 28,318,280; Mennonites and other Baptists, 38,744) .....	28,357,024 (1880)
Norway and Sweden (Norway, 1,805,076; Sweden, 4,561,759, mostly Lutheran) .....	6,366,835 (1875 and 1880)
Denmark and Iceland (Denmark, 1,960,844; Iceland, 72,000, mostly Lutheran) .....	2,032,844 (1880)
Holland (Reformed, 2,346,568—including Remonstrants, 9678; Lutherans, 73,696; Mennonites, 50,705) .....	2,472,680 (1879)
Switzerland (mainly Reformed) .....	1,667,109 (1880)
(Making a total in countries of the Teutonic race of 69,296,492.)	
France (Reformed or Calvinists, 467,531; Lutherans, 80,117; others, 33,109) .....	580,757 (1872)
Belgium, Spain and Portugal, Luxemburg, and Monaco (respectively 15,000, 10,500, 963, and 626) ...	27,059 (various)
Italy (Waldensians, Free Church of Italy, Methodists, Baptists, &c.) .....	62,000 (estimate)
Roumania .....	13,800 (estimate)
(Total in countries of the Latin race, 683,646.)	
Austria (Lutherans, 289,005; Reformed, 110,525; Unitarians, 169, &c.) .....	401,479 (1880)
Hungary (Lutherans, 1,130,150; Reformed, 2,043,280; Unitarians, 56,190) .....	3,229,620 (1880)
Russia in Europe (Lutherans in Finland, 2,019,727) .....	4,504,000 (partly estimate)
Turkey, Greece, Servia (respectively 10,200, 20,000, and 500) .....	30,700 (estimate)
(Total in countries of Slavonic, non-Aryan, and mixed race, 8,165,799.)	
78,145,937	

#### II. AMERICA—

United States (Methodists, 3,686,114 church members; Baptists, 2,424,878; Lutherans, 950,868; Disciples of Christ, 591,821; Congregationalists, 381,697; Episcopalians, 347,781) .....	30,000,000 <sup>1</sup>
Canada .....	2,422,285 (1881)
West Indies .....	160,500 (estimate)
Central and South America .....	180,000 (partly estimate)
32,762,785	

#### III. ASIA and AUSTRALASIA—

India (Anglicans, &c., 373,848; Baptists, Presbyterians, &c., 128,794; Lutherans, 20,577) .....	532,219 (1881)
Dutch Possessions .....	170,000 (partly estimate)
China and Corea (73,000), Japan (13,000), and Siam (2000) .....	88,000 (estimate)
Turkey in Asia (100,000) and Persia (5000) .....	105,000 (estimate)
New South Wales (516,512), Victoria (618,392), Queensland (139,380) .....	1,274,284 (1881)
South Australia (216,626) and West Australia (20,613) .....	237,239 (1881)

822,000	

Total number of Protestants thus ascertained ..... 114,815,436

This total of 115,000,000 is for obvious reasons considerably within the truth. Making allowance for increase of population since some of the census returns, it will probably be not beyond the mark to state the Protestants of Europe at 81,000,000, of America at 34,000,000, of Asia and Australasia at 3,300,000, and of Africa at 850,000, and the total in round numbers at 120,000,000. As regards Europe, compare Brachelli, *Die Staaten Europa's*, 1884. Juraschek in his edition of Otto Hübner's *Geograph.-statistische Tabellen*, 1884, gives 123,000,000 Protestants, or 8.5 per cent. of the total population of the world, which he states at 1,435,000,000.

<sup>1</sup> This estimate of the Protestant population is based on the details of church membership (partly given above) obtained at the census of 1880.

PROTEUS, a Greek sea-god, spoken of by Homer as the Old Man of the Sea. In the *Odyssey* he dwells in the sea near Pharos, an island said to be a day's sail from the mouth of the Nile; in Virgil his home is the Carpathian Sea between Crete and Rhodes. He knew all things past, present, and future, but was very loth to tell what he knew. Those who would consult him had first to surprise and bind him during his noon-day slumber in a cave by the sea, where he was wont to pass the heat of the day surrounded by his seals. Even when caught he would try to escape by assuming all sorts of shapes; now he was a lion, now a serpent, a leopard, a boar, a tree, fire, water. But if his captor held him fast, the god at last returned to his proper shape, gave the wished-for answer, and then plunged into the sea. He was subject to Poseidon, whose finny droves he shepherded under the billows. In post-Homeric times some thought that Proteus was a king of Egypt, at whose court the fair Helen tarried after she had been carried off by Paris, while the Greeks fondly deemed she was in Troy. This is the story followed, with variations, by Herodotus, who got it from Egyptian priests, and by Euripides in his play of *Helen*.

The fairy tale of Proteus has been interpreted in various fanciful ways. Proteus's leading features—his knowledge of the future and his power of assuming any shape at pleasure—are characteristic of the "medicine-men" of savages in many parts of the world. As late as the beginning of our era there was a class of wizards at Rhodes who possessed two at least of the chief marks of "medicine-men"—the powers of transforming themselves and of making rain (*Dict. Sic.*, v. 55). There were rain-makers also at Rome (Festus, s.v. "aquilecium," where see commentary).

PROTEUS ANGUINUS, a blind, newt-like perennibranchiate Amphibian, about a foot long, found in the Adelsberg, Maddalena, and other limestone caverns of Carinthia and Carniola. The creature is white or flesh-coloured, and the transparent gills appear blood red; the skin passes uninterruptedly over the rudimentary eyes. The animal's body is cylindrical; the snout is long and blunt; the fore-feet have three toes, and the hind (which are set very far back) two. There are three gill-arches and two gill-slits on each side. The absence of the fourth branchial arch is a feature that *Proteus* has in common with *Menobranthus* and also with *Spelerpes*. The skull is of an elongated form, and presents several remarkable characters. The trabeculae cranii are persistent, as in the snake. The membrane bones are singularly few, the maxillae being rudimentary and the nasals and supra-occipital absent. In the lower jaw the splenial is said to be absent, but a mento-Meckelian cartilage element is present, as in *Batrachia*. The palatines have a row of teeth, and are ankylosed with the pterygoids; the premaxillae, dentaries, and vomers carry teeth. The absence of a cartilage roof to the nasal cavity is one of the many characters in which *Proteus* agrees with *Menobranthus*, but differs from *Siren* and *Menopoma*. The suspensorium has only a simple pedicle, as in *Batrachia*, and the hyoid arch is remarkable for the enormous hyo-mandibular element, which is larger even than in many sharks. The notochord is scarcely constricted by the amphicelous vertebrae, and the intervertebral cartilages are at a minimum of development. There are twenty-nine trunk vertebrae, one sacral, and twenty-eight caudal. The pectoral arch contains a long thin ossified scapula, a suprascapula, and a long precoracoid separated by a deep notch from the main coracoid; a fissure exists in the glenoid region. There is no sternum. The pectoral girdle is almost identical with that of *Menobranthus*. The pelvis has a narrow tapering ischial region, well-marked prepubes, and (1) a pointed epipubis; this girdle also is extremely like that of *Menobranthus*, but notably different from that of the Axolotl, which is only a pseudo-perennibranchiate,

and whose real affinities are with *Salamander* and *Triton*. The bones of the fore-arm and leg are unankylosed. There are three unossified carpal and tarsal elements, which Gegenbaur identifies as a radiale, ulnare, and a fused distal row; such a carpus has no resemblance to either the embryonic or adult stage of any other amphibian. In the heart the auricular septum is incomplete; the truncus arteriosus bifurcates into two trunks: each divides into two, and the posterior of these again into two, thus forming the three aortic arches on each side. The pulmonary vein sends part only of its blood into the heart, and part into the systemic veins. The blood-corpuscles are the largest known among vertebrates, and are comparable to the exceedingly large corpuscles of the *Dipnoi*. The brain is very small, straight, and embryonic in character. The gut is straight, and the stomach is a scarcely perceptible dilatation. The thyroid (alone among amphibians) is unpaired. The lungs are long simple sacs, expanded distally, as in *Menobranthus*; the trachea is excessively short, and the two cartilages which bound the glottis are continued into long processes which pass to the base of the lungs. As in *Siren*, *Siredon*, and others, the lateral branch of the vagus nerve is connected with a series of sense-organs forming a "lateral line." These characters together indicate the exceedingly low position of *Proteus* among *Amphibia*; it and its close relative the American *Menobranthus* are the lowest of living *Amphibia*. The creature seems to be abundant within its limited habitat; it feeds on worms and small fishes, which in spite of its blindness it catches dexterously. It has bred in captivity, and lays round, isolated eggs, about a third of an inch in diameter. It changes colour slightly in the breeding season, and two rows of reddish spots make their appearance on the hinder part of the body. Such a change seems to indicate that the creature has not always lived in the absolute darkness in which it now spends its life. Individuals differ in some minor characters, and Cope (*Journ. Acad. Philadelphia*, v. p. 103, 1866) has based four new species on Hyrtl's specimens (*P. zosisi*, *carrarae*, *xanthostichus*, *schreiteri*). Merrem altered the name of the genus to *Hypschthion* (*Geoch. der Amphibien*, 1790-1820).

*Authorities*.—*Proteus* was first described by Laurenti in his *Synopsis Reptilium* (Vienna, 1768, p. 37); his locality, Lake Zirknitz, was erroneous. It was next mentioned by Scopoli (*Annus F. Hist. Nat.*, 1772). A full description, with plates, is given by Configliachi and Rusconi (*Del proteo anguino di Laurenti*, 4to, Pavia, 1819). The brain has been described by Treviranus (*P. anguini encephalon*, 4to, Gottingen, 1820), the spinal cord by Klausner (*Rückenmark des P.*, 4to, Munich, 1883), the skull by Parker (*Phil. Trans.*, clxvii. pp. 568-573, 1877), the pectoral arch by Parker (*Shoulder-girdle*, p. 58, pl. iv.), the pelvis by Hoffmann (*Nederl. Arch.*, iii. p. 144, 1877), the vertebral column by Mivart (*P. Z. S.*, 1870), the lateral line, &c., by Bugnion (*Bull. Soc. Faun.*, xii. pp. 259-316, 1873), the eye by Desfosses (*Conyctes rendus*, xciv. p. 1729, 1882), the kidney by Solger (*Abh. Ges. Halle*, xv. p. 405, 1882), the reproduction by Schultze (*Zeits. f. wiss. Zool.*, xxvi. p. 350, 1876) and M. V. Chauvin (*Zeits. f. wiss. Zool.*, xxxviii. 671-685, 1883), and the affinities with *Menobranthus* by Van d. Hoevern (*Arch. Neerl.*, i. p. 305, 1866; *Ann. and Mag. N. H.*, xviii. p. 363, 1866). See also anatomical details by Valentin (*Repert. f. Anat.*, i. p. 282, 1837, vi. p. 353, 1841), and many smaller papers.

PROTOGENES, a Greek painter, born in Caunus on the coast of Caria, but resident in Rhodes during the latter half of the 4th century B.C., was celebrated for the minute and laborious finish which he bestowed on his pictures, both in drawing and in colour. Apelles, his great rival, standing astonished in presence of one of these works, could only console himself that he knew when to stop whereas Protogenes did not. So also Petronius (*Satur.*, 83) experienced a sensation of horror at the too vivid realization of nature in which Protogenes indulged. On one picture, the Ialysus, he spent seven years; on another, the Satyr, he worked continuously during the

siege of Rhodes by Demetrius Poliorcetes (305-4 B.C.) notwithstanding that the garden in which he painted was in the middle of the enemy's camp. Demetrius unsolicited took measures for his safety; more than that, when told that the Ialysus just mentioned was in a part of the town exposed to assault, Demetrius changed his plan of operations. Possibly the slowness and laboriousness of the work of Protogenes was due partly to a want of training in his youth. He appears to have been self-taught; some said that he had begun life as a ship-painter, and, though the painting of certain small figures of ships in a picture of his in Athens, however excellent it may have been, can hardly be held to confirm this account of his youth, it does not on the other hand render the account unreliable. It may have been due also to a want of early training that he found so much difficulty in rendering the foam at the mouth of a dog which occurred in the picture of Ialysus. Angry at his many failures, he dashed the sponge wet with the white colour which he had just wiped off at the mouth of the dog. The result was a perfectly successful foam. Ialysus was a local hero, the founder of the town of the same name in the island of Rhodes, and probably he was represented as a huntsman. The picture was still in Rhodes in the time of Cicero, but was afterwards removed to Rome, where it perished in the burning of the temple of Peace. On another occasion Protogenes seems to have used his sponge with a different effect. The picture painted during the siege of Rhodes consisted of a satyr leaning idly against a pillar on which was a figure of a partridge so life-like that ordinary spectators saw nothing but it. Enraged on this account, the painter wiped out the partridge. The Satyr must have been one of his last works. He would then be about seventy years of age, and had enjoyed for about twenty years a reputation next only to that of Apelles, his friend and benefactor. Both were finished colourists so far as the fresco-painting of their day permitted, and both were laborious in the practice of drawing, doubtless with the view to obtaining bold effects of perspective as well as fineness of outline. It was an illustration of this practice when Apelles, finding in the house of Protogenes a large panel ready prepared for a picture, drew upon it with a brush a very fine line which he said would tell sufficiently who had called. Protogenes on his return home took a brush with a different colour and drew a still finer line along that of Apelles dividing it in two. Apelles called again; and, thus challenged, drew with a third colour another line within that of Protogenes, who then admitted himself surpassed. This panel was seen by Pliny (*N.H.*, xxxv. 83) in Rome, where it was much admired, and where it perished by fire. In the gallery of the Propylæa at Athens was to be seen the panel by Protogenes in which occurred the figures of ships already mentioned. The subject consisted of two figures representing personifications of the coast of Attica, Paralus and Hammonias, to whom the presence of ships would be the more appropriate as the Athenians actually possessed two ships so named. For the council chamber at Athens he painted figures of the Thesmothetæ, but in what form or character is not known. Probably these works were executed in Athens, and it may have been then that he met Aristotle, who recommended him to take for subjects the deeds of Alexander the Great. In his Alexander and Pan he may have followed that advice in the idealizing spirit to which he was accustomed. To this spirit must be traced also his Cydippe and Tlepolemus, legendary personages of Rhodes. Among his portraits are mentioned those of the mother of Aristotle, Philiscus the tragic poet, and King Antigonus. But Protogenes was also a sculptor to some extent, and made several bronze statues of athletes, armed figures, huntsmen, and persons in the act of offering sacrifices.

**PROTOPLASM.** In most of the biological articles already before the reader, whether concerned with general questions, as BIOLOGY, ANATOMY, BOTANY, EMBRYOLOGY, EVOLUTION, HISTOLOGY, MORPHOLOGY, PHYSIOLOGY, &c., or even with special groups of living beings, as ANIMAL KINGDOM, FORAMINIFERA, FUNGUS, PROTOZOA, &c., special reference has been made to protoplasm as the living matter from which all kinds of living beings are formed and developed, and to the properties of which all their functions are ultimately referred. Fundamentally important then as this substance is, whether we occupy the standpoint of morphology, physiology, or ætiology, an attempt must be made to outline the way in which our knowledge of it has been reached, to bring together by the aid of a short summary the statements of such preceding articles, and to supply means of extending the general idea thus obtained by reference to the original literature of the subject.

§ 1. *History.*—Among the varied and fruitful observations of the early microscopists, Rösel v. Rosenhof's excellent account (1755) of his "*Proteus animalcule*" (the familiar *Amœba*) is especially noteworthy as the earliest description of the form and movements of what we now know as a mass of living protoplasm. Such discoveries as those of rotation in the cell of *Chara* (Corti, 1772), and of similar movements in other plant cells (*Vallisneria*, Meyen, 1827; *Tradescantia*, R. Brown, 1831), are also memorable,—more so indeed in this relation than is the great contemporaneous movement in general histology, since this, though aided by the rapid improvement of the microscope, eagerly carried on by the united labours of zoologists and botanists, headed by Johannes Müller and Robert Brown, and culminating in the hands of Schleiden and Schwann (1838-39) in the fundamental morphological generalization of the cell theory (see MORPHOLOGY), included views of the structure, origin, and function of the cell-substance alike erroneous and misleading. Knowledge had in fact to start afresh from the level of the unappreciated discovery of Rosenhof; and it is accordingly from the observations of Dujardin on *Foraminifera* (1835) that our modern knowledge of protoplasm dates. His main account is still worth reading in his own words. In proposing the term "sarcode," he says, "je propose de nommer ainsi ce que d'autres observateurs ont appelé une gelée vivante, cette substance glutineuse, diaphane, insoluble dans l'eau, se contractant en masses globuleuses, s'attachant aux aiguilles de dissection, et se laissant étirer comme du mucus, enfin se trouvant dans tous les animaux inférieurs interposée aux autres éléments de structure." Though thus dissipating many errors, and placing the study of the lowest forms of life on its true basis, Dujardin unfortunately did not see the full bearing of his discovery. He recognized his sarcode, however, in the polyps, and noted that the ova of the slug exhibited similar movements. The next important step was not taken until 1846, when the botanist Hugo von Mohl, working on quite independent lines, reached a clearly defined conception of the vegetable cell, not only, as usual hitherto, distinguishing the cell wall and the nucleus from the cell contents (*Zellsaft*), but also the "tough, slimy, granular, semi-fluid" constituent from the watery cell-sap hitherto generally confused with it under the common name. For this substance (which Schleiden had already vaguely mentioned as "Schleim") he proposed the term "protoplasma" (*πρώτος*, first, *πλάσμα*, formed substance). The discovery of the amœboid movements of colourless blood-corpuscles dates from the same year, and the basis was thus prepared for Ecker's acute comparison (1849) of the "formed contractile substance" of muscle with the "unformed contractile substance" of the lowest types of animal life. This

speculation, so profoundly anticipatory of our present standpoint (see *PHYSIOLOGY*), was greatly strengthened when Donders shortly afterwards succeeded in referring contractility from the cell-membrane to the cell-substance. Cohn's researches among microscopic plants and animals, and particularly his study of the transition, which at that time seemed so marvellous and so perplexing, from plant-like quiescence to animal-like activity, exhibited by the protoplasm of such an alga as *Protococcus* on escaping from its cell-wall, led him to suggest that vegetable protoplasm and animal sarcode, "if not identical, must be at any rate in the highest degree analogous substances." This speculation again ran too far in advance of current conceptions, dominated as these were by the errors which accompanied the cell-theory, and another decade of research was needed for its establishment. This was effected on several simultaneous and convergent lines. The botanical evidence culminated in De Bary's classical monograph of the *Myxomycetes* (1859); the study of the segmentation of the ovum, and the rapid advance of animal histology, both largely due to Kölliker, were of marked importance; while the clear identification of the vegetable "protoplasm" with the animal "sarcode," requiring, as it did, a mastery of all these lines and results of inquiry, was finally effected by M. SCHULTZE (*q.v.*), whose researches on *Foraminifera* (1854), and subsequent admirable studies in animal histology, prepared him to accomplish the definite reform of the cell-theory. This he did by fully and finally replacing (1861-63) the early conception of the cell as an all-important membrane enclosing a nucleus surrounded by fluid by that of a unit-mass of living matter or protoplasm (the nucleus alone being viewed as essential, the wall or membrane no longer so). Our present usage of the term protoplasm for the living substance of the animal as well as of the plant dates from Schultze's paper ("Ueber Muskelkörperchen und das was man eine Zelle zu nennen habe," *Arch. f. Anat. u. Physiol.*, 1861); and the term sarcode, notwithstanding Dujardin's priority, has since lapsed into disuse, save to some extent among French authors.

This rejuvenescence of the cell theory, in a form pointing to a far deeper unity of the forms and processes of organic nature than its founders had ventured to dream, marks the commencement of a new epoch of detailed investigation of all the forms, aspects, conditions, and products of protoplasmic life; but in this movement the workers are too numerous for mention save in so far as may be incidental in the following scanty reference to some of their main results (1).<sup>1</sup>

§ 2. *Appearance and Properties of Protoplasm*.—To obtain a notion of the appearance and physical properties of protoplasm, it is expedient as it were to repeat the process of discovery, and acquire concrete ideas by actual observation as far as possible, or at least from good figures. The *Amoeba* (see *PROTOZOA*) and the *FORAMINIFERA* (*q.v.*) thus afford convenient and classical examples of the protoplasm of the lowest animal forms; the colourless corpuscles of blood should also be examined, and the structure of the higher tissues (see *ANATOMY* and *HISTOLOGY*) inquired into, and the segmentation of an ovum (see *REPRODUCTION*) observed,—most conveniently perhaps in frog spawn. Vegetable examples are readily obtained from the cells of a growing shoot (see *BOTANY*, vol. iv. pp. 83 *sq.*, figs. 1 and 6); while the living cells of *Chara* (*BOTANY*, fig. 7) and other examples of protoplasmic movement should be observed. Thus, with the aid of the descriptive passages to be found in the articles referred to at the outset, a tolerably clear idea of a mass of protoplasm, with its contained granules of various kinds and its sap-vacuoles, will

be obtained; and its frequent differentiation into an outer layer or ectoplasm, clearer and denser, passing into an inner layer or endoplasm, usually more fluid and granular, will be noted. A finely reticulated structure of the protoplasm may also be made out in many cases; the nucleus (inconspicuous since equally refracting with the protoplasm during life, but brought out clearly after death by the process of internal digestion of the surrounding protoplasm, or by the application of dyes and other reagents), and its contained nucleolus, as well as the cell-wall when present, will be observed. Wide variations of consistency will thus be noted from the comparatively solid, almost brittle, state of the quiescent protoplasm of some seeds to its thin, syrupy, and largely vacuolated state in a growing vegetable tissue (*cf.* *BOTANY*, fig. 6). Such structural inquiries are now in active progress, especially in connection with the process of cell division (see *HISTOLOGY*, *REPRODUCTION*), and many questions of detail are more or less under active dispute, *e.g.*, the relation of the nucleus to the protoplasm, the existence or constancy of an internal network (the "stroma") in both, the conditions of occurrence of that continuity of protoplasm lately shown to exist through the cell walls of many vegetable tissues, and so on (2).

§ 3. *Manifestations of Life (Functions)*.—The vital properties or "functions" exhibited by undifferentiated living protoplasm (*e.g.*, *Amoeba*) are usually enumerated as contractility, irritability and automatism, reception and assimilation of food, metabolism with secretion and excretion, respiration, and reproduction. Thus we have represented all those functions which in higher animals seem to be confined to special tissues—which we accordingly recognize as muscular or nervous, secretory or excretory, respiratory, reproductive, or the like. Yet in these organs, however apparently specialized to one function only, a residue of all or nearly all the other fundamental properties of protoplasm remains and may be redeveloped; and thus those functional changes (necessarily accompanying morphological evolution or change of environment) which we call "adaptation" and those pathological disturbances which we term "disease" are alike provided for. See *BIOLOGY*, *PATHOLOGY*, *SELECTION AND VARIATION*, also (3).

§ 4. *External Conditions of Life*.—See *BIOLOGY*.

§ 5. *Experimental Modification of the Conditions of Life*.—The behaviour of protoplasm under various modifications of physical conditions has been investigated by Schultze, Kühne, Strasburger, Engelmann, and others, while not a few researches are also extant as to the behaviour of living cells under various chemical stimuli, among which those of Darwin (see *INSECTIVOROUS PLANTS*) and Frommann may be mentioned as especially suggestive. See also *SCHIZOMYCETES*, *NUTRITION*, and (4).

§ 6. *Chemical Composition and Processes*.—This aspect of protoplasm is of constantly increasing importance, since for the chemist all functions alike can only be viewed in terms of those specific anabolic or katabolic changes which to the physiologist, on the other hand, seem mere accompaniments of them (see *PHYSIOLOGY*, *NUTRITION*, *REPRODUCTION*). The determination of the chemical nature of protoplasm is thus the supreme problem of physiological chemistry; and, while, thanks to the labours of Reinke, E. Schultze, and others, there has been a rapidly increasing knowledge of its anastates, but more especially of its katabates, and of many cases of the unity of metabolic processes throughout nature, several daring general hypotheses are already in the field. Of these that of Schützenberger, who views proteid bodies as complex ureides, and that of Loew and Bokorny, who regard them as a complex mixture of aldehyde groups, are examples. See (5).

§ 7. *Molecular Constitution*.—Many hypotheses as to the minute structure of protoplasm have been proposed; thus

<sup>1</sup> These numbers refer to the bibliography at p. 830.

Spencer resolves protoplasm into "physiological units," Haeckel into "plastidules," while Darwin accounts for heredity by reference to the properties of supposed "gemmules," Engelmann suggests the existence of "contractile units" (*isotagmen*), &c.; but those various hypotheses, framed mostly for special purposes, still await more general criticism. See (6).

§ 8. *Origin of Protoplasm.*—See ABIOGENESIS, BIOLOGY, REPRODUCTION, and (7).

*Bibliography.*—In addition to the articles above referred to, the reader may with advantage consult the following works, from which complete bibliographical details can be obtained. ## PROTOZOA

PROTOZOA is the name applied to the lowest grade of the animal kingdom, and originated as a translation of the German term "Urthiere." Whilst at first used some forty years ago in a vague sense, without any strict definition, so as to include on the one hand some simple organisms which are now regarded as plants and on the other some animals which are now assigned a higher place in the animal series, the term has within the last twenty years acquired a very clear signification.

The Protozoa are sharply and definitely distinguished from all the rest of the animal kingdom, which are known by the names "Metazoa" or "Enterozoa." They are those animals which are structurally single "cells" or single corpuscles of protoplasm, whereas the Enterozoa consist of many such units arranged definitely (in the first instance) in two layers—an endoderm or enteric cell-layer and an ectoderm or deric cell-layer—around a central cavity, the enteron or common digestive cavity, which is in open communication with the exterior by a mouth.

The Protozoa are then essentially unicellular animals. The individual or person in this grade of the animal kingdom is a single cell; and, although we find Protozoa which consist of aggregates of such cells, and are entitled to be called "multicellular," yet an examination of the details of structure of these cell-aggregates and of their life-history establishes the fact that the cohesion of the cells in these instances is not an essential feature of the life of such multicellular Protozoa but a secondary and non-essential arrangement. Like the budded "persons" forming, when coherent to one another, undifferentiated "colonies" among the Polyps and Corals, the coherent cells of a compound Protozoon can be separated from one another and live independently; their cohesion has no economic significance. Each cell is precisely the counterpart of its neighbour; there is no common life, no distribution of function among special groups of the associated cells, and no corresponding differentiation of structure. As a contrast to this we find even in the simplest Enterozoa that the cells are functionally and structurally distinguishable into two groups—those which line the enteron or digestive cavity and those which form the outer body wall. The cells of these two layers are not interchangeable; they are fundamentally different in properties and structure from one another. The individual Enterozoon is not a single cell; it is an aggregate of a higher order consisting essentially of a digestive cavity around which two layers of cells are

disposed. The individual Protozoon is a single cell; a number of these individuals may, as the result of the process of fission (cell-division), remain in contact with one another, but the compound individual which they thus originate has not a strong character. The constituent cells are still the more important individualities; they never become differentiated and grouped in distinct layers differing from one another in properties and structure; they never become subordinated to the individuality of the aggregate produced by their cohesion; hence we are justified in calling even these exceptional aggregated Protozoa unicellular.

By far the larger number of Protozoa are absolutely single isolated cells, which, whenever they duplicate themselves by that process of division common to these units of structure (whether existing as isolated organisms or as constituents of the tissues of plants or of animals), separate at once into two distinct individuals which move away from one another and are thenceforward strangers.

Whilst it is easy to draw the line between the Protozoa and the Enterozoa or Metazoa which lie above them, on account of the perfectly definite differentiation of the cells of the latter into two primary tissues, it is more difficult to separate the Protozoa from the parallel group of unicellular plants.

Theoretically there is no difficulty about this distinction. There is no doubt that organisms present themselves to us in two great series starting in both cases from simple unicellular forms. The one series, the plants, can take up the carbon, hydrogen, oxygen, and nitrogen necessary to build up their growing protoplasm from mineral compounds soluble in water, compounds which constitute the resting stage of those elements in the present physical conditions of our planet. Plants can take their nitrogen in the form of ammonia or in the form of nitrates and their carbon in the form of carbonic acid. Accordingly they require no mouths, no digestive apparatus; their food being soluble in water and diffusible, they absorb at all or many points of their surface. The spreading diffuse form of plants is definitely related to this fact. On the other hand the series of organisms which we distinguish as animals cannot take the nitrogen, necessary to build up their protoplasm, in a lower state of combination than it presents in the class of compounds known as albumens; nor can they take carbon in a lower state of combination than it presents when united with hydrogen or with

hydrogen and oxygen to form fat, sugar, and starch. Albumens and fats are not soluble in water and diffusible; they have to be seized by the animal in the condition of more or less solid particles, and by chemical processes superinduced in the living protoplasm of the animal by the contact of these particles they are acted upon, chemically modified, and rendered diffusible. Hence the animal is provided with a mouth and a digestive cavity, and with organs of locomotion and prehension by which it may search out and appropriate its scattered nutriment. Further the albumens, fats, sugars, and starch which are the necessary food of an animal are not found in nature excepting as the products of the life of plants or of animals; accordingly all animals are in a certain sense parasitic upon either plants or other animals. It would therefore seem to be easy to draw the line between even the most minute unicellular plants and the similarly minute unicellular animals—assigning those which feed on the albumens, &c., of other organisms by means of a mouth and digestive apparatus to the animal series, and those which can appropriate the elements of ammonia, nitrates, and carbonates to the plants.

Such absolute distinctions lending themselves to sharp definitions have, however, no place in the organic world; and this is found to be equally true whether we attempt to categorically define smaller groups in the classification of plants and animals or to indicate the boundaries of the great primary division which those familiar names imply. Closely allied to plants which are highly and specially developed as plants, and feed exclusively upon ammonia, nitrates, and carbonates, we find exceptionally modified kinds which are known as "insectivorous plants" and are provided with digestive cavities (the pitchers of pitcher-plants, &c.), and actually feed by acting chemically upon the albumens of insects which they catch in these digestive receptacles. No one would entertain for a moment the notion that these insectivorous plants should be considered as animals. The physiological definition separating plant from animal breaks down in their case; but the consideration of the probable history of their evolution as indicated by their various details of structure suffices at once to convince the most sceptical observer that they actually belong to the vegetable line of descent or family tree, though they have lost the leading physiological characteristic which has dominated the structure of other plants. In this extreme case it is made very obvious that in grouping organisms as plants or as animals we are not called upon to apply a definition but to consider the multifarious evidences of historical evolution. And we find in the case of the Protozoa and the Protophyta that the same principle holds good, although, when dealing with extremely simple forms, it becomes much more difficult to judge of the genetic relationship of an organism in proportion as the number of detailed points of possible agreement with and divergence from other forms to which it may be supposed to be related are few.

The feeding of plants upon carbonic acid is invariably accompanied by the presence of a peculiar green-colouring matter—chlorophyll. In virtue of some direct or indirect action of this chlorophyll the protoplasm of the plant is enabled to seize the carbon of the mineral world—the carbon which has sunk to the lowest resting stage of combination—and to raise it into combination with hydrogen and oxygen and ultimately with nitrogen. There are plants which have no chlorophyll and are thus unable to feed upon carbonic acid. They are none the less plants since they agree closely with particular chlorophyll-bearing plants in details of form and structure, mode of growth and reproduction. A large series of these are termed Fungi. Though unable to feed on carbonic acid, they do

not feed as do animals. They can take their carbon from acetates and tartrates, which animals cannot do, and their nitrogen from ammonia. Even when it is admitted that some of these colourless plants, such as the Bacteria (Schizomycetes), can act upon albumens so as to digest them and thus nourish themselves, it is not reasonable to place the Bacteria among animals, any more than it would be reasonable so to place *Nepenthes*, *Sarracenia*, and *Drosera* (insectivorous Phanerogams). For the structure and mode of growth of the Bacteria is like that of well-known chlorophylliferous minute Algae from which they undoubtedly differ only in having secondarily acquired this peculiar mode of nutrition, distinct from that which has dominated and determined the typical structure of plants.

So we find in a less striking series of instances amongst animals that here and there the nutritional arrangements which we have no hesitation in affirming to be the leading characteristic of animals, and to have directly and perhaps solely determined the great structural features of the animal line of descent, are largely modified or even altogether revolutionized. The green *Hydra*, the freshwater *Sponge*, and some *Planarian* worms produce chlorophyll corpuscles in the protoplasm of their tissues just as green plants do, and are able in consequence to do what animals usually cannot do—namely, feed upon carbonic acid. The possibilities of the protoplasm of the plant and of the animal are, we are thus reminded, the same. The fact that characteristically and typically plant protoplasm exhibits one mode of activity and animal protoplasm another does not prevent the protoplasm of even a highly developed plant from asserting itself in the animal direction, or of a thoroughly characterized animal, such as the green *Hydra*, from putting forth its chlorophylliferous powers as though it belonged to a plant.

Hence it is not surprising that we find among the Protozoa, notwithstanding that they are characterized by the animal method of nutrition and their forms determined by the exigencies of that method, occasional instances of partial vegetable nutrition such as is implied by the development of chlorophyll in the protoplasm of a few members of the group. It would not be inconsistent with what is observed in other groups should we find that there are some unicellular organisms which must, on account of their structural resemblances to other organisms, be considered as Protozoa and yet have absolutely given up altogether the animal mode of nutrition (by the ingestion of solid albumens) and have acquired the vegetable mode of absorbing ammonia, nitrates, and carbonic acid. Experiment in this matter is extremely difficult, but such "vegetable" or "holophytic nutrition" appears to obtain in the case of many of the green *Flagellata*, of the *Dinoflagellata*, and possibly of other Protozoa.

On the other hand there is no doubt that we may fall into an error in including in the animal line of descent all unicellular organisms which nourish themselves by the ingestion of solid nutriment. It is conceivable that some of these are exceptional creophagous Protophytes parallel at a lower level of structure to the insectivorous Phanerogams. In all cases we have to balance the whole of the evidence and to consider probabilities as indicated by a widely-reaching consideration of numerous facts.

The mere automatic motility of unicellular organisms was at one time considered sufficient indication that such organisms were animals rather than plants. We now know that not only are the male reproductive cells of ferns and similar plants propelled by vibratile protoplasm, but such locomotive particles are recognized as common products ("swarm-spores" and "zoospores") of the lowest plants.

The danger of dogmatizing erroneously in distinguish-

ing Protozoa from Protophyta, and the insuperable difficulty in really accomplishing the feat satisfactorily, has led at various times to the suggestion that the effort should be abandoned and a group constituted confessedly containing both unicellular plants and unicellular animals and those organisms which may be one or the other. Haeckel has proposed to call this group the Protista (1).<sup>1</sup> On the whole, it is more satisfactory to make the attempt to discriminate those unicellular forms which belong to the animal line of descent from those belonging to the vegetable line. It is, after all, not a matter of much consequence if the botanist should mistakenly claim a few Protozoa as plants and the zoologist a few Protophyta as animals. The evil which we have to avoid is that some small group of unattractive character should be rejected both by botanist and zoologist and thus our knowledge of it should unduly lag. Bearing this in mind the zoologist should accord recognition as Protozoa to as wide a range of unicellular organisms as he can without doing violence to his conception of probability.

A very interesting and very difficult subject of speculation forces itself on our attention when we attempt to draw the line between the lowest plants and the lowest animals, and even comes again before us when we pass in review the different forms of Protozoa.

That subject is the nature of the first protoplasm which was evolved from not-living matter on the earth's surface. Was that first protoplasm more like animal or more like vegetable protoplasm as we know it to-day? By what steps was it brought into existence?

Briefly stated the present writer's view is that the earliest protoplasm did not possess chlorophyll and therefore did not possess the power of feeding on carbonic acid. A conceivable state of things is that a vast amount of albuminoids and other such compounds had been brought into existence by those processes which culminated in the development of the first protoplasm, and it seems therefore likely enough that the first protoplasm fed upon these antecedent steps in its own evolution just as animals feed on organic compounds at the present day, more especially as the large creeping plasmodia of some Mycetozoa feed on vegetable refuse. It indeed seems not at all improbable that, apart from their elaborate fructification, the Mycetozoa represent more closely than any other living forms the original ancestors of the whole organic world. At subsequent stages in the history of this archaic living matter chlorophyll was evolved and the power of taking carbon from carbonic acid. The "green" plants were rendered possible by the evolution of chlorophyll, but through what ancestral forms they took origin or whether more than once, i.e., by more than one branch, it is difficult even to guess. The green Flagellate Protozoa (Volvoxineae) certainly furnish a connecting point by which it is possible to link on the pedigree of green plants to the primitive protoplasm: it is noteworthy that they cannot be considered as very primitive and are indeed highly specialized forms as compared with the naked protoplasm of the Mycetozoon's plasmodium.

Thus then we are led to entertain the paradox that though the animal is dependent on the plant for its food yet the animal preceded the plant in evolution, and we look among the lower Protozoa and not among the lower Protophyta for the nearest representatives of that first protoplasm which was the result of a long and gradual evolution of chemical structure and the starting point of the development of organic form.

#### *The Protozoon Cell-Individual compared with the Typical Cell of Animal and Vegetable Tissues.*

##### MORPHOLOGY.

The Protozoon individual is a single corpuscle of protoplasm, varying in size when adult from less than the  $\frac{1}{1000}$ th of an inch in diameter (some Sporozoa and Flagellata) up to a diameter of an inch (Nummulites), and even much larger size in the plasmodia of Mycetozoa. The substance of the Protozoa exhibits the same general properties—irritability, movement, assimilation, growth, and division—and the same irremediable chemical alteration as the result of exposure to a moderate heat, which are observed in the protoplasm constituting the corpuscles known as cells which build up the tissues of the larger animals and

plants. There is therefore no longer any occasion to make use of the word "sarcode" which before this identity was established was very usefully applied by Dujardin (2) to the substance which mainly forms the bodies of the Protozoa. Like the protoplasm which constitutes the "cells" of the Enterozoa and of the higher plants, that of the Protozoon body is capable of producing, by chemical processes which take place in its substance (over and above those related merely to its nutrition), a variety of distinct chemical compounds, which may form a deposit in or beyond the superficial protoplasm of the corpuscle or may accumulate centrally. These products are therefore either ectoplasmic or entoplasmic. The chemical capacities of protoplasm thus exhibited are very diverse, ranging from the production of a denser variety of protoplasm, probably as the result of dehydration, such as we see in the nucleus and in the cortical substance of many cells, to the chemical separation and deposition of membranes of pure chitin or of cellulose or of shells of pure calcium carbonate or quasi-crystalline needles of silica.

**NUCLEUS.**—The nucleus is probably universally present in the Protozoon cell, although it may have a very simple structure and be of very small size in some cases. The presence of a nucleus has recently been demonstrated by means of appropriate staining reagents in some Protozoa (shell-bearing Reticularia or Foraminifera and many Mycetozoa) where it had been supposed to be wanting, but we are not yet justified in concluding absolutely that there are not some few Protozoa in which this central differentiation of the protoplasm does not exist; it is also a fact that in the young forms of some Protozoa which result from the breaking up of the body of the parent into many small "spores" there is often no nucleus present.

In contrast to this it is the fact that the cells which build up the tissues of the Enterozoa are all derived from the division of a nucleated egg-cell and the repeated division of its nucleated products, and are invariably nucleated. The same is true of tissue-forming plants, though there are a few of the lowest plants, such as the Bacteria, the protoplasm of which presents no nucleus. In spite of recent statements (3) it cannot be asserted that the cells or protoplasmic corpuscles of the yeast-plant (*Saccharomyces*) and of the hyphae of many simple moulds contain a true nucleus. We are here brought to the question "What is a true nucleus?" The nucleus which is handed on from the egg-cell of higher plants and Enterozoa to the cells derived from it by fission has lately been shown to possess in a wide variety of instances such very striking characteristics that we may well question whether every more or less distinctly outlined mass or spherule of protoplasm which can be brought into view by colouring or other reagents, within the protoplasmic body of a Protozoon or a Protophyte, is necessarily to be considered as quite the same thing as the nucleus of tissue-forming egg-cell-derived cells.

Researches, chiefly due to Flemming (4), have shown that the nucleus in very many tissues of higher plants and animals consists of a capsule containing a plasma of "achromatin" not deeply stained by reagents, ramifying in which is a reticulum of "chromatin" consisting of fibres which readily take a deep stain (Fig. I, A). Further it is demonstrated that, when the cell is about to divide into two, definite and very remarkable movements take place in the nucleus, resulting in the disappearance of the capsule and in an arrangement of its fibres first in the form of a wreath (Fig. I, D) and subsequently (by the breaking of the loops formed by the fibres) in the form of a star (E). A further movement within the nucleus leads to an arrangement of the broken loops in two groups (F), the position of the open ends of the broken loops being reversed

<sup>1</sup> These numbers refer to the bibliography at p. 866.

as compared with what previously obtained. Now the two groups diverge, and in many cases a striated appearance of the achromatin substance between the two groups of loops of chromatin is observable (H). In some cases (especially egg-cells) this striated arrangement of the achromatin substance precedes the separation of the loops (G). The striated achromatin is then termed a "nucleus-spindle," and the group of chromatin loops (Fig. I, G, a)

FIG. I.—Karyokinesis of a typical tissue-cell (epithelium of Salamander) after Flemming and Kleim. The series from A to I represent the successive stages in the movement of the chromatin fibres during division, excepting G, which represents the "nucleus-spindle" of an egg-cell. A, resting nucleus; D, wreath-form; E, single star, the loops of the wreath being broken; F, separation of the star into two groups of U-shaped fibres; H, diaster or double star; I, completion of the cell-division and formation of two resting nuclei. In G the chromatin fibres are marked *a*, and correspond to the phase shown in F; they are in this case called the "equatorial plate"; *b*, achromatin fibres forming the nucleus-spindle; *c*, granules of the cell-protoplasm forming a "polar star." Such a polar star is seen at each end of the nucleus-spindle, and is not to be confused with the diaster H.

is known as "the equatorial plate." At each end of the nucleus-spindle in these cases there is often seen a star consisting of granules belonging to the general protoplasm of the cell (G, c). These are known as "polar stars." After the separation of the two sets of loops (H) the protoplasm of the general substance of the cell becomes constricted, and division occurs, so as to include a group of chromatin loops in each of the two fission products. Each of these then rearranges itself together with the associated achromatin into a nucleus such as was present in the mother-cell to commence with. This phenomenon is termed "karyokinesis," and has been observed, as stated above, in a large variety of cells constituting tissues in the higher animals and plants.

There is a tendency among histologists to assume that this process is carried out in all its details in the division of all cells in the higher plants and animals, and accordingly to assume that the structural differentiation of achromatin plasma and chromatin nucleus-fibres exists in the normal nucleus of every such cell. If this be true, it is necessary to note very distinctly that the nucleus of the Protozoon cell-individual by no means conforms universally to this model. As will be seen in the sequel, we find cases in which a close approach is made by the nucleus of Protozoa to this structure and to this definite series of movements during division (Fig. VIII. 3 to 12, and Fig. XXV.); and a knowledge of these phenomena has thrown light upon some appearances (conjugation of the Ciliata) which were previously misinterpreted. But there are Protozoa with a deeply-placed nucleus-like structure which does not present the typical structure above described nor the typical changes during division, but in which on the contrary the nucleus is a very simple homogeneous corpuscle or vesicle of more readily stainable protoplasm.

The difficulties of observation in this matter are great, and it is proportionately rash to generalize; but it appears that we are justified at the present moment in asserting that not all the cells even of higher plants and animals

exhibit in full detail the structure and movement of the typical cell-nucleus above figured and described; and accordingly the fact that such structure and movement cannot always be detected in the Protozoon cell-nucleus must not be regarded as either an isolated phenomenon peculiar to such Protozoon cells, nor must it be concluded that we have only to improve our means of analysis and observation in order to detect this particular structure in all nuclei. It seems quite possible and even probable that nuclei may vary in these details and yet be true nuclei. Some nuclei which are observed in Protozoon cell-bodies may be regarded as being at a lower stage of differentiation and specialization than are those of the epithelial and embryonic cells of higher animals which exhibit typical karyokinesis. Others on the contrary, such as the nuclei of some Radiolaria (*vide infra*), are probably to be regarded as more highly developed than any tissue cell-nuclei, and will be found by further study to present special phenomena peculiar to themselves. In some of the highest Protozoa (the Ciliata) it has lately been shown that the nucleus may have no existence as such, but is actually dispersed throughout the protoplasm in the form of fine particles of chromatin-substance which stain on treatment with carmine but are in life invisible (84). This diffuse condition of the nuclear matter has no parallel, at present known, in tissue-cells, and curiously enough occurs in certain genera of Ciliata whilst in others closely allied to them a solid single nucleus is found. The new results of histological research have necessitated a careful study of the nucleus in its various stages of growth and division in the cell-bodies of Protozoa and a comparison of the features there observed with those established as "typical" in tissue-cells. Accordingly we have placed the figure and explanation of the typical cell-nucleus in the first place in this article for subsequent reference and comparison.

**CORTICAL SUBSTANCE.**—The superficial protoplasm of an embryonic cell of an Enterozoon in the course of its development into a muscular cell undergoes a change which is paralleled in many Protozoa. The cortical layer becomes dense and highly refringent as compared with the more liquid and granular medullary substance. Probably this is essentially a change in the degree of hydration of the protoplasm itself, although it may be accompanied by the deposition of metamorphic products of the protoplasm which are not chemically to be regarded as protoplasm. The differentiation of this cortical substance (which is not a frequent or striking phenomenon in tissue-cells) may be regarded as an ectoplasmic (*i.e.*, peripheral) modification of the protoplasm, comparable to the entoplasmic (central) modification which produces a nucleus.

The formation of "cortical substance" in the Protozoa furnishes the basis for the most important division into lower and higher forms, in this assemblage of simplest animals. A large number (the Gymnomyxa) form no cortical substance; their protoplasm is practically (excepting the nucleus) of the same character throughout. A nearly equally large number (the Corticata) develop a complete cortical layer of denser protoplasm, which is distinct from the deeper medullary protoplasm. This layer is permanent, and gives to the body a definite shape and entails physiological consequences of great moment. The cortical protoplasm may exhibit further specialization of structure in connexion with contractile functions (muscular).

**ECTOPLASMIC PRODUCTS CHEMICALLY DISTINCT FROM PROTOPLASM.**—The protoplasm of all cells may throw down as a molecular precipitate distinct from itself chemical compounds, such as chitin and horny matter and other nitrogenized bodies, or again non-nitrogenous compounds, such as cellulose. Very usually these substances are deposited not external to but in the superficial proto-

plasm. They are then spoken of as cell-cuticle if the cell bounds the free surface of a tissue, or as matrix or cell-wall in other cases. The Protozoon cell-body frequently forms such "cuticles," sometimes of the most delicate and evanescent character (as in some *Amœbæ*), at other times thicker and more permanent. They may give indications (though proper chemical examination is difficult) of being allied in composition to chitin or gelatin, in other instances to cellulose, which is rare in animals and usual in plants. These cuticular deposits may be absent, or may form thin envelopes or in other cases jelly-like substance intimately mixed with the protoplasm (*Radiolaria*). They may take the form of hooks, tubercles, or long spines, in their older and more peripheral parts free from permeation by protoplasm, though deeply formed in and interpenetrated by it. Such pellicles and cuticles, the deeper layers (if not the whole) of which are permeated by protoplasm, lead insensibly to another category of ectoplasmic products in which the material produced by the protoplasm is separated from it and can be detached from or deserted by the protoplasm without any rupture of the latter. These are—

*Shells and Cysts.*—Such separable investments are formed by the cell-bodies of many Protozoa, a phenomenon not exhibited by tissue-cells. Even the cell-walls of the protoplasmic corpuscles of plant tissues are permeated by that protoplasm, and could not be stripped off without rupture of the protoplasm. The shell and the cyst of the Protozoon are, on the contrary, quite free from the cell-protoplasm. The shell may be of soft chitin-like substance (*Gromia*, &c.), of cellulose (*Labyrinthula*, *Dinoflagellata*), of calcium carbonate (*Globigerina*, &c.), or of silica (*Clathrulina*, *Codonella*). The term "cyst" is applied to completely closed investments ("shells" having one or more apertures), which are temporarily produced either as a protection against adverse external conditions or during the breaking up of the parent-cell into spores. Such cysts are usually horny.

*Stalks.*—By a localization of the products of ectoplasmic activity the Protozoon cell can produce a fibre or stalk of ever-increasing length, comparable to the seta of a Chaetopod worm produced on the surface of a single cell.

**ENTOPLASTIC PRODUCTS DISTINCT FROM PROTOPLASM.**—Without pausing here to discuss the nature of the finest granules which are embedded as a dust-cloud in the hyaline matrix of the purest protoplasm alike of Protozoa and of the cells of higher animals and plants, and leaving aside the discussion of the generalization that all protoplasm presents a reticular structure, denser trabeculae of extreme minuteness traversing more liquid material, it is intended here merely to point to some of the coarser features of structure and chemical differentiation, characteristic of the cell-body of Protozoa.

With regard to the ultimate reticular structure of protoplasm it will suffice to state that such structure has been shown to obtain in not a few instances (e.g., *Lithamœba*, Fig. V.), whilst in most Protozoa the methods of microscopy at present applied have not yielded evidence of it, although it is not improbable that a reticular differentiation of the general protoplasm similar to that of the nucleus may be found to exist in all cells.

Most vegetable cells and many cells of animal tissues exhibit vacuolation of the protoplasm; i.e., large spaces are present in the protoplasm occupied by a liquid which is not protoplasm and is little more than water with diffusible salts in solution. Such vacuoles are common in Protozoa. They are either permanent, gastric, or contractile.

*Permanent vacuoles* containing a watery fluid are sometimes so abundant as to give the protoplasm a "bubbly" structure (*Thalamophora*, *Radiolaria*, &c.), or may merely give to it a trabecular character (*Trachelius*, Fig. XXIV.

14, and *Noctiluca*, Fig. XXVI. 18). Such vacuoles may contain other matters than water, namely, special chemical secretions of the protoplasm. Of this nature are oil-drops, and from these we are led to those deposits within the cell-protoplasm which are of solid consistence (see below).

*Gastric vacuoles* occur in the protoplasm of most Protozoa in consequence of the taking in of a certain quantity of water with each solid particle of food, such ingestion of solid food-particles being a characteristic process bound up with their animal nature.

*Contractile vacuoles* are frequently but not universally observed in the protoplasm of Protozoa. They are not observed in the protoplasm of tissue-cells. The contractile vacuole whilst under observation may be seen to burst, breaking the surface of the Protozoon and discharging its liquid contents to the exterior; its walls, formed of undifferentiated protoplasm, then collapse and fuse. After a short interval it re-forms by slow accumulation of liquid at the same or a neighbouring spot in the protoplasm. The liquid is separated at this point by an active process taking place in the protoplasm which probably is of an excretory nature, the separated water carrying with it nitrogenous waste-products. A similar active formation of vacuoles containing fluid is observed in a few instances (*Arcella*, some *Amœbæ*) where the protoplasm separates a gas instead of liquid, and the gas vacuole so produced appears to serve a hydrostatic function.

*Corpuscular and Amorphous Entoplasmic Solids.*—Concretions of undetermined nature are occasionally formed within the protoplasm of Protozoon cells, as are starch and nitrogenized concretions in tissue-cells (*Lithamœba*, Fig. V. *conc.*). But the most important corpuscular products after the nucleus, which we have already discussed, are chlorophyll corpuscles. These are (as in plants) concavo-convex or spherical corpuscles of dense protoplasm resembling that of the nucleus, which are impregnated superficially with the green-coloured substance known as chlorophyll. They multiply by fission, usually tetraschistic, independently of the general protoplasm. They occur in representatives of many different groups of Protozoa (*Proteomyxa*, *Heliozoa*, *Labyrinthulida*, *Flagellata*, *Ciliata*), but are confined to a few species. Similar corpuscles or band-like structures coloured by other pigments are occasionally met with (*Dinoflagellata*).

Recently it has been maintained (Brandt, 5) that the chlorophyll corpuscles of Protozoa and other animals are parasitic *Algæ*. But, though it is true that parasitic *Algæ* occur in animal tissues, and that probably this is the nature of the yellow cells of *Radiolaria*, yet there seems to be no more justification for regarding the chlorophyll corpuscles of animal tissue-cells and of Protozoa as parasites than there is for so regarding the chlorophyll corpuscles of the leaves of an ordinary green plant.

Corpuscles of starch, paramylum, and other amyloid substances are commonly formed in the *Flagellata*, whose nutrition is to a large extent plant-like.

*Entoplasmic Fibres.*—A fibrillation of the protoplasm of the Protozoon cell-body may be produced by differentiation of less and more dense tracts of the protoplasm itself. But as distinct from this we find horny fibres occasionally produced within the protoplasm (*Heliozoa*) having definite skeletal functions. The threads produced in little cavities in the superficial protoplasm of many Ciliate Protozoa, known as trichocysts, may be mentioned here.

*Entoplasmic Spicules.*—Needle-like bodies consisting either of silica or of a horny substance (acanthin) are produced in the protoplasm of many Protozoa (*Heliozoa*, *Radiolaria*). These are known as spicules; they may be free or held together in groups and arranged either radially or tangentially in reference to the more or less spherical

body of the Protozoon. A similar production of siliceous spicules is observed in the tissue-cells of Sponges. Crystals of various chemical nature (silica, calcium carbonate, oxalate, &c.) are also frequently deposited in the protoplasm of the Protozoa, differing essentially from spicules in that their shape is due purely to crystallization.

**GENERAL FORM OF THE PROTOZOON CELL.**—Those Protozoa which have not a differentiated cortical substance, and are known as Gymnomyxa, present very generally an extreme irregularity of contour. Their protoplasm, being liquid rather than viscous, flows into the most irregular shapes. Their fundamental form when at rest is in many cases that of the sphere; others are discoidal or may be monaxial, that is to say, show a differentiation of one region or "end" of the body from the other. Frequently the protoplasm is drawn out into long threads or filaments which radiate uniformly from all parts of the spherical or discoidal cell-body or originate from one region to the exclusion of other parts of the surface.

These non-corticate Protozoa can take solid particles of food into their protoplasm, there to be digested in an extemporized "gastric vacuole," at any part or most parts of their superficies. They have no permanent cell-mouth leading into the soft protoplasm since that soft protoplasm is everywhere freely exposed.

The corticate Protozoa have (with the exception of some parasites) one, and in the Acinetaria more than one, definite aperture in the cortical substance leading into the softer medullary protoplasm. This is the cell-mouth,—morphologically as distinct from the mouth of an Enterozoon as is the hole in a drain pipe from the front door of a house, but physiologically subserving the same distinctively animal function as does the mouth of multicellular animals. The general form of the body is in these Protozoa oblong, with either monaxial symmetry, when the mouth is terminal, or bilateral symmetry, when the body is oblong and flattened and the mouth is towards one end of what becomes by its presence the "ventral" surface. Though the protoplasm is not nakedly exposed in irregular lobes and long filaments in these corticate Protozoa so as to pick up at all points such food-particles as may fall in its way, yet the protoplasm does in most Corticata project in one or more peculiarly modified fine hair-like processes from the otherwise smooth surface of the cell-body. These processes are *vibratile cilia*, identical in character with the vibratile cilia of epithelial tissue-cells of Enterozoa. They are essentially locomotor and current-producing (therefore prehensile) organs, and, whilst unable to ingest solid food-particles themselves, serve to propel the organism in search of food and to bring food into the cell-mouth by the currents which they excite. Either a single vibratile filament is present, when it is called a flagellum, or a row or many rows of cilia are developed.

Constituent cells of the Enterozoa are well known which closely resemble some of the Gymnomyxa or non-corticate Protozoa in their general form. These are the colourless blood corpuscles or lymph corpuscles or phagocytes (Mecznikow, 6) which float freely in the blood and ingest solid particles at any part of their surface as do non-corticated Protozoa; they exhibit a similar irregularity and mutability of outline, and actually digest the particles which they take in. The endodermal digestive cells of some Enterozoa (Coelentera and Planarians) are also naked protoplasmic corpuscles and can take in solid food-particles.

No tissue-cells are known which present any close parallel to the mouth-bearing corticate Protozoa. The differentiation of the structure of a single cell has in these forms reached a very high degree, which it is not surprising to find without parallel among the units which build up the individual of a higher order known as an Entero-

zoon. Cilia are developed on such cell-units (ciliated epithelium), but not used for the introduction of food-particles into the cell. In rare cases (the ciliated "pots" of the vascular fluid of Sipunculus) they act so as to freely propel the ciliated cell through the liquid "blood" of the Enterozoon, as the cilia of a Protozoon propel it through water. An aperture in the cortical substance (or in the cuticular product) of a tissue-cell is sometimes to be observed, but is never (?) used for the ingestion of food-particles. Such an aperture occurs in unicellular glands, where it serves as the outlet of the secretion.

#### PHYSIOLOGY.

*Motion.*—As has just been hinted, the movement of protoplasm, which in the tissue-cells of Enterozoa and higher plants is combined and directed so as to produce effects in relation to the whole organism built up of countless cells, is seen in the Protozoa in a different relation, namely, as subserving the needs of the individual cell of which the moving protoplasm is the main substance. The phenomena known in tissue-cells as "streaming" (e.g., in the cells of the hairs of Tradescantia), as local contraction and change of form (e.g., in the corpuscles of the cornea), as muscular contraction, and as ciliary movement are all exhibited by the protoplasm of the cell-body of Protozoa, with more or less constancy, and are intimately related to the processes of hunting, seizing, and ingesting food, and of the intercourse of the individuals of a species with one another and their evasion of hostile agencies. Granule streaming and the implied movement of currents in the protoplasm are seen in the filamentous protoplasm of the Heliozoa, Radiolaria, Reticularia, and Noctiluca, and in the cyclosis of the gastric vacuoles of Ciliata. Local contraction and change of form is seen best in the Amœbæ and some Flagellata, where it results in locomotion. Definite muscular contraction is exhibited by the protoplasmic band in the stalk of Vorticella, by the leg-like processes of the Hypotrichous Ciliata, and by the cortical substance of some large Ciliata. Ciliary movement ranging from the vibration of filaments of protoplasm temporarily evolved, up to the rhythmic beat of groups of specialized cilia, is observed in all groups of Protozoa in the young condition if not in the adult, and special varieties of ciliary movement and of cilia-like organs will be noted below. For an account of the conditions and character of protoplasmic movement generally which cannot be discussed in the present article the reader is referred to Engelmann (7).

The protoplasm of the cell-body of the Protozoa is drawn out into lobes and threads which are motile and are used as locomotive and prehensile organs. These processes are of two kinds, which are not present on the same cell and are not capable of transmutation, though there are exceptions to both of these statements. The one kind are termed "pseudopodia," and are either lobose or filamentous or branched and even reticular (Figs. IV. and IX.). The Protozoa which exhibit them are sometimes termed Myxopods. The other kind are cilia and flagella, and are simple threads which are alternately bent and straightened almost incessantly during the life of the organism. These Protozoa are termed Mastigopods. Whilst the cilia and flagella are permanent organs, the pseudopodia vary greatly in character; they are in some cases rapidly expanded and withdrawn in irregular form, and can hardly be said to be more than lobose protuberances of the flowing moving mass of protoplasm. In other cases they are comparatively permanent stiff threads of protoplasm which can be contracted and can fuse with one another but rarely do so (Heliozoa, Radiolaria). Between these extreme forms of "pseudopodia" there are numerous intermediate varieties, and the

whole protoplasmic body of the Protozoon may even assume the form of a slowly changing network of threads of greater or less tenuity (*Chlamydomyxa*, Fig. VI).

*Nutrition.*—Typically—that is to say, by determinate hereditary tendency—the Protozoa take solid food-particles into their protoplasm which form and occupy with the water surrounding them “gastric vacuoles” in the protoplasm. The food-particle is digested in this vacuole, by what chemical processes is not ascertained. It has been shown that the contents of the gastric vacuole give in some cases an acid reaction, and it is not improbable that free acid is secreted by the surrounding protoplasm. It is not known whether any ferment<sup>1</sup> is separated by the protoplasm, but it is probable from observations made on the digestive process of *Cœlentera* (*Actiniae*) that the ferment is not separated, but that actual contact of the food-particle with the protoplasm is necessary for a “ferment influence” to be exerted. The digestion of a food-particle by a Protozoon is intra-cellular, and has been contrasted with the cavitary digestion of higher animals. In the latter, ferments and acids are poured out by the cells bounding the enteric cavity into that space, and digestion is extra-cellular. In the lowest Enterozoa (many *Cœlentera* and some Planarian worms) it has been shown that food-particles are actually taken up in a solid state by the soft protoplasm of the enteric cells and thus subjected to intra-cellular digestion. There appears to be a gradual transition from this process, in which close contact with living protoplasm is necessary that the solution of an albuminous food-particle may be effected, onwards to the perfectly free cavitary digestion by means of secretions accumulated in the enteron.

We have not yet any satisfactory observations on the chemistry of intra-cellular digestion either of Protozoa or of *Cœlentera*.

Certain Protozoa which are parasitic do not take solid food particles; they (like higher parasites, such as the Tapeworms) live in the nutritious juices of other animals and absorb these by their general surface in a liquid state. The Gregarinæ (Sporozoa), many Ciliata, &c., are in this case. Other Protozoa are known which are provided with chlorophyll corpuscles and do not take in solid food, but, apparently as a result of exceptional adaptation in which they differ from closely-allied forms, nourish themselves as do green plants. Such are the Volvocinean Flagellata and some of the Dinoflagellata. It has also been asserted that other Protozoa (*viz.*, some Ciliata)—even some which possess a well-developed mouth—can (and experimentally have been made to) nourish themselves on nitrogenous compounds of a lower grade than albumens—such, for instance, as ammonium tartrate. Any such assertions must be viewed with the keenest scepticism, since experimental demonstration of the absence of minute albuminous particles (*e.g.*, Bacteria) from a solution of ammonium tartrate in which Ciliate Protozoa are flourishing is a matter of extreme difficulty and has not yet been effected.

Undigested food-remnants are expelled by the protoplasm of the Protozoon cell either at any point of the surface or by the cell-mouth or by a special cell-anus (some Ciliata, see Fig. XXIV. 22).

*Respiration and Excretion.*—The protoplasm of the Protozoa respire, that is, takes up oxygen and liberates carbonic acid, and can readily be shown experimentally to require a supply of oxygen for the manifestation of its activity. No special respiratory structures are developed in any Protozoa, and as a rule also the products of oxidation appear to be washed out and removed from the protoplasm without the existence of any special apparatus.

<sup>1</sup> The digestive ferment pepsin has been detected by Krakenberg in the plasmodium of the Mycetozoon *Fuligo* (flowers of tan). See on this subject Zopf (13), p. 88.

The contractile vacuole which exists in so many Protozoa appears, however, to be an excretory organ. It has been shown to rapidly excrete in a state of solution colouring matters (anilin blue) which have been administered with food particles (8). No evidence has been adduced to show whether traces of nitrogenous waste-products are present in the water expelled by the contractile vacuole.

*Chemical Metamorphosis.*—The form which the various products of the activity of the Protozoon's protoplasm may assume has been noted above. It will be sufficient here to point out that the range of chemical capacities is quite as great as in the cells of the higher Enterozoa. Chitin, cellulose, silicon, calcium carbonate, fats, pigments, and gases can be both deposited and absorbed by it. Owing to the minuteness of the Protozoa, we are at present unable to recognize and do justice to the variety of chemical bodies which undoubtedly must play a part in their economy as the result of the manufacturing activity of their protoplasm. See, however, Zopf (13), p. 71.

*Growth and Reproduction.*—The Protozoon cell follows the same course as tissue-cells, in that by assimilation of nutriment its protoplasm increases in volume and reaches a certain bulk, when its cohesion fails and the viscid droplet divides into two. The coefficient of cohesion varies in different genera and species, but sooner or later the disrupting forces lead to division, and thus to multiplication of individuals or reproduction. The phenomena connected with the division of the nucleus (already alluded to) will be noticed in particular cases below.

Whilst simple binary division is almost without exception a chief method of reproduction among the Protozoa, it is also very usual, and probably this would be found if our knowledge were complete to have few exceptions, that under given conditions the Protozoon breaks up rapidly into many (from ten to a hundred or more) little pieces, each of which leads an independent life and grows to the form and size of its parent. It will then multiply by binary division, some of the products of which division will in their turn divide into small fragments. The small fragments are called “spores.” Usually the Protozoon before breaking up into spores forms a “cyst” (see above) around itself. Frequently, but not as a necessary rule, two (rarely three or more) Protozoon cell-individuals come together and fuse into one mass before breaking up into spores. This process is known as “conjugation;” and there can be no doubt that the physiological significance of the process is similar to that of sexual fertilization, namely, that the new spores are not merely fragments of an old individual but are something totally new inasmuch as they consist of a combination of the substance of individuals who have had different life experiences.

Whilst spore-formation is not necessarily preceded by conjugation, conjugation is not necessarily followed by spore-formation. Among the Mycetozoa the young individuals produced from spores conjugate at a very early period of growth in numbers and form “plasmodia,” and after a considerable interval of feeding and growth the formation of spores takes place. Still more remarkable is the fact observed among the Ciliata where two individuals conjugate and after a brief fusion and mixture of their respective protoplasm separate, neither individual (as far as certain genera at least are concerned) breaking up into spores, but simply resuming the process of growth and recurrent binary division with increased vigour.

There is certainly no marked line to be drawn between reproduction by simple fission and reproduction by spore-formation; both are a more or less complete dividing of the parent protoplasm into separate masses; whether the products of the first fission are allowed to nourish themselves and grow before further fission is carried out or not

does not constitute an essential difference. The fission of the Ciliate Protozoon, *Opalina* (see below Fig. XXIV. 4-8), is a step from the ordinary process of delayed binary division towards spore-formation. In some Protozoa spores are produced after encystation by a perfectly regular process of cleavage (comparable to the cleavage of the egg-cell of Enterozoa)—first two, then four, then eight, sixteen, and thirty-two fission products being the result (see Fig. XX. 24, 25, &c.).

But more usually there is a hastening of the process, and in these cases it is by no means clear what part the parent cell-nucleus takes. An encysted Gregarina (or two conjugated Gregarinae) suddenly breaks up into a number of equal-sized spores, which do not increase in number by binary division and have not been formed by any such process. This multicentral segregation of the parent protoplasm is a marked development of the phenomenon of sporulation and remote from ordinary cell-division. How it is related to ordinary cell-division is not known, inasmuch as the changes undergone by the nucleus in this rapid multicentral segregation of the parent protoplasm have not been determined. The spores of Protozoa may be naked or encased singly or in groups in little envelopes, usually of a firm horny substance (see Fig. XX. 23 to 26, and Fig. XXIV. 15 to 18). Whenever the whole or a part of a Protozoon cell divides rapidly into a number of equal-sized pieces which are simultaneously set free and are destined to reproduce the adult form, the term spore is applied to such pieces, but the details of their formation may vary and also those of their subsequent history. In typical cases each spore produced as the result of the fission of an encysted Protozoon (conjugated or single) has its own protective envelope, as in the Mycetozoa (Fig. III.) and the Sporozoa (Fig. XVIII.), from which the contained protoplasm escapes by "germination" as a naked corpuscle either flagellate or amoebiform. In some terminologies the word "spore" is limited to such a "coated" spore, but usually the naked protoplasmic particles which issue from such "coated" spores, or are formed directly by the rapid fission of the parent Protozoon, are also called "spores." The former condition is distinguished as a "chlamydospore," whilst the latter are termed "gymnospores." Many Protozoa produce gymnospores directly by the breaking up of their protoplasm, and these are either "flagellulae" (swarm-spores) or "amebulae" (creeping spores). The production of coated spores is more usual among the lower plants than it is among Protozoa, but is nevertheless a characteristic feature of the Gregarinae (Sporozoa) and of the Mycetozoa. The term "gemma" or "bud-spore" is applied to cases, few in number, where (as in *Acinetaria*, Fig. XXVI, *Spirochona*, Fig. XXIII. 10, and *Reticularia*, Fig. X. 8) the spores are gradually nipped off from the parent-cell one or more at a time. This process differs from ordinary cell-division only in the facts (1) that the products of division are of unequal size—the parent-cell being distinguishable as the larger and more complete in structure, and (2) that usually the division is not binary, but more than one bud-spore is produced at a time.

Whilst in the binary cell-division of the Protozoa the two products are usually complete in structure at the period of separation, spores and spore-buds are not only of small size and therefore subject to growth before attaining the likeness of the parent, but they are also very often of simple and incomplete structure. The gap in this respect between the young spore and its parent necessarily varies according to the complexity of the parental form.

In the case of the Radiolaria, of the Gregarinae, of Noctiluca, and of the Acinetaria, for instance, the spore has before it a considerable process of development in

structure and not merely of growth, before attaining the adult characters. Hence there is a possible embryology of the Protozoa, to the study of which the same principles are applicable as are recognized in the study of the embryology of Enterozoa. Embryonic forms of great simplicity of structure, often devoid of nucleus, and consisting of simple elongate particles of protoplasm, are hatched from the spore-cases of the Gregarinae (Fig. XVII. 13, 14). These gradually acquire a differentiated cortical protoplasm and a nucleus. A very large number of *Gymnomyxa* produce spores which are termed "monadiform," that is, have a single or sometimes two filaments of vibratile protoplasm extended from their otherwise structureless bodies. By the lashing of these flagella the spores (swarm-spores or zoospores) are propelled through the water. The resemblance of these monadiform young (best called "flagellulae") to the adult forms known as Flagellata has led to the suggestion that we have in them a case of recapitulative development, and that the ancestors of the *Gymnomyxa* were Protozoa similar to the Flagellata. Again the *Acinetaria* produce spores which are uniformly clothed with numerous vibratile cilia (Fig. XXVI.), although the adults are entirely devoid of such structures; this is accounted for by the supposition that the *Acinetaria* have been developed from ancestors like the Ciliata, whose characters are thus perpetuated in their embryonic stages. There can be little doubt that these embryological suggestions are on the whole justified, and that the nucleated Protozoa are the descendants of non-nucleated forms similar to the spores of *Gymnomyxa* and Sporozoa, whilst it seems also extremely probable that the ancestral Protozoa were neither exclusively amoeboid in the movement of their protoplasm nor provided with permanent vibratile filaments (flagella and cilia); they were neither Myxopods nor Mastigopods (to use the terms which have been introduced to express this difference in the character of the locomotor processes), but the same individuals were capable of throwing out their protoplasm sometimes in the form of flowing lobes and networks, sometimes in the form of vibratile flagella. A few such undifferentiated forms exist at the present day among the *Proteomyxa* and in a little more advanced condition among the lowest Flagellata, e.g., *Ciliophrys*.

*Death.*—It results from the constitution of the Protozoon body as a single cell and its method of multiplication by fission that death has no place as a natural recurrent phenomenon among these organisms. Among the Enterozoa certain cells are separated from the rest of the constituent units of the body as egg-cells and sperm-cells; these conjugate and continue to live, whilst the remaining cells, the mere carriers as it were of the immortal reproductive cells, die and disintegrate. There being no carrying cells which surround, feed, and nurse the reproductive cells of Protozoa, but the reproductive cell being itself and alone the individual Protozoon, there is nothing to die, nothing to be cast off by the reproductive cell when entering on a new career of fission. The bodies of the higher animals which die may from this point of view be regarded as something temporary and non-essential, destined merely to carry for a time, to nurse, and to nourish the more important and deathless fission-products of the unicellular egg. Some of these fission-products of the new individual developed from an egg-cell—namely, the egg-cells and sperm-cells—are as immortal as the unicellular Protozoon. This method of comparing the unicellular and the multicellular organism is exceedingly suggestive, and the conception we thus gain of the individuality of the Enterozoon throws light upon the phenomena of reproduction and heredity in those higher organisms.

Experiment and observation in this matter are extremely

difficult; but we have no reason to suppose that there is any inherent limit to the process of nutrition, growth, and fission, by which continuously the Protozoa are propagated. The act of conjugation from time to time confers upon the protoplasm of a given line of descent new properties, and apparently new vigour. Where it is not followed by a breaking up of the conjugated cells into spores, but by separation and renewed binary fission (Ciliata), the result is described simply as "rejuvenescence." The protoplasm originated by the successive division of substance traceable to one parent cell has become specialized, and in fact too closely adapted to one series of life-conditions; a fusion of substance with another mass of protoplasm equally specialized, but by experience of a somewhat differing character, imparts to the resulting mixture a new combination of properties, and the conjugated individuals on separation start once more on their deathless career with renewed youth.

#### CLASSIFICATION OF THE PROTOZOA.

In attempting a scheme of classification it would be most in accordance with the accepted probabilities of the ancestral history of the Protozoa to separate altogether those forms devoid of a nucleus from those which possess one, and to regard them as a lower "grade" of evolution or differentiation of structure.

By some systematists, notably Bütschli (9), the presence or absence of a nucleus has not been admitted as a basis of classificatory distinction, whilst on the other hand both Haeckel (1) and Huxley (10) have insisted on its importance.

The fact is that during recent years many of those Protozoa which were at one time supposed to be devoid of nucleus even in a rudimentary form, and furnished therefore the tangible basis for a lowest group of "Protozoa Homogenea" or "Monera," have been shown by the application of improved methods of microscopic investigation to possess a nucleus, that is to say, a differentiated corpuscle of denser protoplasm lying within the general protoplasm, and capable when the organism is killed by alcohol or weak acids of taking up the colour of various dyes (such as carmine and hematoxylin) more readily and permanently than is the general protoplasm. In such cases the nucleus may be very small and exhibit none of the typical structure of larger nuclei. It is usually surrounded by a clear (i.e., non-granular) halo of the general protoplasm which assists the observer in its detection. Nuclei have been discovered in many Reticularia (Foraminifera), a group in which they were supposed to be wanting, by Schultze (11) and the Hertwigs (12) and more recently in the Mycetozoa and in Vampyrella and Protomonas (Zopf, 13), where so excellent an observer as Cienkowski had missed them.

It seems therefore not improbable that a nucleus is present though not observed in Protomyxa, Myxastrum, and other similar forms which have been by Haeckel and others classed as "Monera" or "Homogenea." The recently described (14) *Archerina* (Fig. II. 8, 11) certainly possesses no nucleus in the usual sense of that term, but it is possible that the chlorophyll-coloured corpuscles of that organism should be considered as actually representing the nucleus. Whilst then refraining from asserting that there are no existing Protozoa devoid of nucleus corresponding in this character with non-nucleate Protophyta, such as the Bacteria, we shall not in our scheme of classification institute a group of Homogenea, but shall leave the taking of that step until it has been shown after critical examination that those forms now regarded by some observers as Homogenea are really so. In the meantime these forms will find their places alongside of the Nucleata most nearly allied to them in other characters.

The Protozoa with a definite permanent cortical substance of differentiated protoplasm are undoubtedly to be regarded as evolved from forms devoid of such differentiation of their substance, and we accordingly take this feature as the indication of a primary division of the Protozoa.<sup>1</sup> The lower grade, the Gymnomyxa, afford in other respects evidence of their being nearly related to the ancestral forms from which the Corticata (the higher grade) have developed. The Gymnomyxa all or nearly all, whilst exhibiting amoeboid movement and the flowing of their protoplasm into "pseudopodia" of very varied shapes, produce spores which swim by means of one or two flagella of vibratile protoplasm (monadiform young or flagellulae). These flagellate young forms

are closely related to the Flagellata, a group of the Corticata from which it seems probable that the Dinoflagellata, the Ciliata, and the Acinetaria have been derived. The Gymnomyxa themselves cannot, on account of the small number of structural features which they offer as indications of affinity and divergence in genetic relationships *inter se*, be classified with anything like confidence in a genealogical system. We are obliged frankly to abandon the attempt to associate some of the simpler forms with their nearest genetic allies and to content ourselves with a more or less artificial system, which is not, however, artificial in so far as its main groups are concerned. Thus the genetic solidarity of each of the large classes Heliozoa, Reticularia, Mycetozoa, and Radiolaria is not open to question. The Lobosa on the other hand appear to be a more artificial assemblage, and it is difficult to say that genetically there is any wide separation between them and the Mycetozoa or between the Mycetozoa and some of the simpler forms which we bring together under the class Proteomyxa.

The scheme of classification which we adopt is the following:—

#### PROTOZOA.

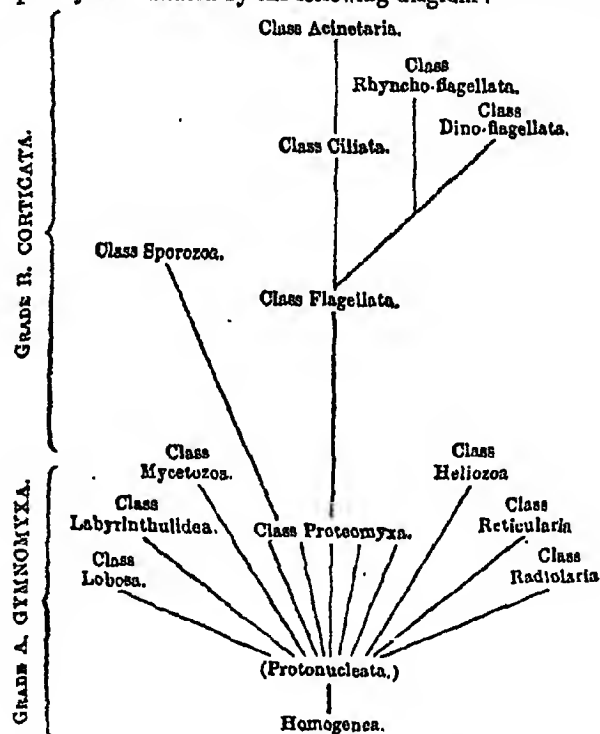

##### GRADE A. GYMNOXYXA.

Sections.	
Proteana.	Class I. PROTEOMYXA. Ex. <i>Vampyrella</i> , <i>Protomyxa</i> , <i>Archerina</i> .
Plasmodiata.	Class II. MYCETOZOA. Ex. The <i>Eumycetozoa</i> of Zopf.
Lobosa.	Class III. LOBOSA. Ex. <i>Amœba</i> , <i>Arcella</i> , <i>Pelomyxa</i> .
	Class IV. LABYRINTHULIDEA. Ex. <i>Labyrinthula</i> , <i>Chlamydomyxa</i> .
	Class V. HELIOZOA.
Filosa.	Ex. <i>Actinophrys</i> , <i>Raphidiophrys</i> , <i>Clathrulina</i> .
	Class VI. RETICULARIA. Ex. <i>Gromia</i> , <i>Lituola</i> , <i>Astrorhiza</i> , <i>Globigerina</i> .
	Class VII. RADIOLARIA. Ex. <i>Thalassicola</i> , <i>Eucyrtidium</i> , <i>Acanthometra</i> .

##### GRADE B. CORTICATA.

Lipostoma.	Class I. SPOROZOA. Ex. <i>Gregarina</i> , <i>Oocidium</i> .
	Class II. FLAGELLATA. Ex. <i>Monas</i> , <i>Salpingoza</i> , <i>Euglena</i> , <i>Volvox</i> .
	Class III. DINOFLAGELLATA. Ex. <i>Prorocentrum</i> , <i>Ceratium</i> .
Stomatophora.	Class IV. RHYNCHOFAGELLATA. Ex. <i>Noctiluca</i> .
	Class V. CILIATA. Ex. <i>Vorticella</i> , <i>Paramœcium</i> , <i>Sientor</i> .
	Class VI. ACINETARIA. Ex. <i>Acineta</i> , <i>Dendrosoma</i> .

The genetic relationships which probably obtain among these groups may be indicated by the following diagram:—

*Literature.*—Certain works of an older date dealing with microscopic organisms, and therefore including many Protozoa, have historical interest. Among these we may cite O. F. Müller, *Animalcula Infusoria*, 1786; Ehrenberg, *Infusionsthierehen*, 1838;

<sup>1</sup> The "exoplasm" and "endoplasm" described in *Amœba*, &c., by some authors are not distinct layers but one and the same continuous substance—what was internal at one moment becoming external at another, no really structural difference existing between them.

doubt is justified in regard to Haeckel's *Protamæba primitiva*, which was observed by him in pond water and differs from *Protogenes* in having lobose pseudopodia, whilst agreeing with it in absence of nuclei, contractile vacuoles, and other differentiation of structure.

FIG. II.—Various *Proteomyxa*. 1. *Protomyxa aurantiaca*, Haeckel, plasmodium phase. The naked protoplasm shows branched, reticulate processes (pseudopodia), and numerous non-contractile vacuoles. It is in the act of engulfing a *Ceratium*. Shells of engulfed *Ciliata* (*Tintinnabula*) are embedded deeply in the protoplasm *a*. 2. Cyst phase of *Protomyxa*. *a*, transparent cyst-wall; *b*, protoplasm broken up into spores. 3. Flagellula phase of *Protomyxa*, the form assumed by the spores on their escape from the cyst. 4. Amœbula phase of the same, the form assumed after a short period by the flagellulae. 5. *Vampyrella spirogyra*, Cienk., amœba phase penetrating a cell of *Spirogyra* *b*, by a process of its protoplasm *c*, and taking up the substance of the *Spirogyra* cell, some of which is seen within the *Vampyrella* *a*. 6. Large individual of *Vampyrella*, showing pseudopodia *c*, and food particles *a*. The nucleus (though present) is not shown in this drawing. 7. Cyst phase of *Vampyrella*. The contents of the cyst have divided into four equal parts, of which three are visible. One is commencing to break its way through the cyst-wall *f*; *a*, food particles. 8. *Archerina Boltoni*, Lankester, showing lobose and filamentous protoplasm, and three groups of chlorophyll corpuscles. The protoplasm *g* is engulfing a *Bacterium* *t*. 9. Cyst phase of *Archerina*. *a*, spinous cyst-wall; *b*, green-coloured contents. 10. Chlorophyll corpuscle of *Archerina* showing tetrachistie division. 11. Actinophryd form of *Archerina*. *b*, chlorophyll corpuscles. 12. *Protogenes primordialis*, Haeckel (*Amœba porrecta*, M. Schultze), from Schultze's figure.

The structureless protoplasmic network described by Haeckel

from spirit-preserved specimens of Atlantic ooze and identified by him with Huxley's (28) *Bathybins*, as also the similar network described by Bessels (29) as *Protobathybins*, must be regarded for the present as insufficiently known.

It is possible that these appearances observed in the ooze dredged from great depths in the Atlantic are really due to simple Protozoa. On the other hand it has been asserted by Sir Wyville Thomson, who at one time believed in the independent organic nature of *Bathybins*, that the substance taken for protoplasm by both Huxley and Haeckel is in reality a gelatinous precipitate of calcium sulphate thrown down by the action of alcohol upon sea-water. Other naturalists have pointed to the possibility of the protoplasmic network which Bessels studied in the living condition on board ship being detached portions of the protoplasm of *Reticularia* and *Radielana*. The matter is one which requires further investigation.

*Archerina Boltoni* is the name given by Lankester (14) to a very simple *Gymnomyxon* inhabiting freshwater ponds in company with *Desmids* and other simple green Algae (Fig. II. 8 to 11). *Archerina* exhibits an amœba phase in which the protoplasm is thrown into long stiff filaments (Fig. II. 11), surrounding a spherical central mass about  $\frac{1}{1000}$  inch in diameter (actinophryd form). A large vacuole (non-contractile) is present, or two or three small ones. No nucleus can be detected by careful use of reagents in this or other phases. The protoplasm has been seen to ingest solid food particles (*Bacteria*) and to assume a lobose form. The most striking characteristic of *Archerina* is the possession of chlorophyll corpuscles. In the actinophryd form two oval green-coloured bodies (*b*, *b*) are seen. As the protoplasm increases by nutrition the chlorophyll corpuscles multiply by quaternary division (Fig. II. 10) and form groups of four or of four sets of four symmetrically arranged. The division of the chlorophyll corpuscles is not necessarily followed by that of the protoplasm, and accordingly specimens are found with many chlorophyll corpuscles embedded in a large growth of protoplasm (Fig. II. 8); the growth may increase to a considerable size, numbering some hundreds of chlorophyll corpuscles, and a proportionate development of protoplasm. Such a growth is not a plasmodium, that is to say, is not formed by fusion of independent amœba forms, but is due to continuous growth. When nutrition fails the individual chlorophyll corpuscles separate, each carrying with it an investment of protoplasm, and then each such amœba form forms a cyst around itself which is covered with short spines (Fig. II. 9). The cysts are not known to give rise to spores, but appear to be merely hypocysts.

The domination of the protoplasm by the chlorophyll corpuscles is very remarkable and unlike anything known in any other organism. Possibly the chlorophyll corpuscles are to be regarded as nuclei, since it is known that there are distinct points of affinity between the dense protoplasm of ordinary nuclei and the similarly dense protoplasm of normal chlorophyll corpuscles.

## CLASS II. MYCETOZOA, De Bary.

*Characters*.—*Gymnomyxa* which, as an exception to all other Protozoa, are not inhabitants of water but occur on damp surfaces exposed to the air. They are never parasitic, as are some of the *Proteomyxa* most nearly allied to them (*Plasmodiophora*, &c.), but feed on organic debris. They are structurally characterized by the fact that the amœba forms, which develop either directly or through flagellulae from their spores, always form large, sometimes very large, i.e., of several square inches area, fusion plasmodia (or rarely aggregation plasmodia), and that the spores are always chlamydospores (i.e., provided with a coat) and are formed either in naked groups of definite shape (sori) or on the surface of peculiar columns (conidiophores) or in large fruit-like cysts which enclose the whole or a part of the plasmodium and develop besides the spores definite sustentacular structures (capillitium) holding the spores in a mesh-work.

Three orders of Mycetozoa are distinguishable according to the arrangement of the spores in more or less complex spore-fruits.

### ORDER 1. SOROPHORA, Zopf.

*Characters*.—Mycetozoa which never exhibit a vibratile (monadiform) swarmspore or flagellula phase, but hatch from the spore as amœbæ. A true fusion plasmodium is not formed, but an aggregation plasmodium by the contact without fusion of numerous amœba forms. The spore fruit is a naked aggregation of definitely arranged encysted amœbæ called a sorus, not enclosed in a common capsule; each encysted amœba has the value of a single spore and sets free on germination a single amœbula. They inhabit the dung of various animals.

*Genera*.—*Copromyxa*, Zopf; *Cynhulina*, Cienk.; *Dictyostelium*, Brefeld; *Acrasis*, Van Tieghem; *Polyspondylium*, Brefeld.

### ORDER 2. ENDOSPOREA, Zopf.

*Characters*.—Mycetozoa always passing through the flagellula phase and always forming true plasmodia by fusion of amœba forms. The spore-fruit is in the form of a large cyst which encloses a quantity of the plasmodium; the latter then breaks up into (*a*)

spores (one corresponding to each nucleus of the enclosed plasmodium) each of which has a cellulose coat, and (b) a capillitium of threads which hold the spores together. Each spore (chlamydospore) liberates on germination a single nucleated flagellula, which develops into an amoeba, which in turn fuses with other amoebulae to form the plasmodium. The Endosporea are essentially dwellers on rotten wood and such vegetable refuse.

FIG. III.—Mycetozoa (after De Bary). 1-6. Germination of spore (1) of *Trichia varia*, showing the emerging "flagellula" (4, 5), and its conversion into an "amoeba" (6). 7-18. Series leading from spore to plasmodium phase of *Chondriodermis difforme*:—7, spore; 8, flagellula; 9, amoeba; 10, plasmodium; 11-17, stages; 18, plasmodium. 19, 20. Spore-cyst (cyst) of *Phylarium leucophaeum*, Fr. (x 25), the former from the surface, the latter in section with the spores removed to show the sustentacular network or capillitium. 21. Section of the spore-cyst of *Didymium squamulosum*, with the spores removed to show the radiating capillitium x and the stalk.

#### Sub-order 1. PERITRICHIA, Zopf.

Fam. 10. LICEACEAE.  
Genera.—*Licea*, Schrader; *Tubulina*, Pers.; *Lindbladia*, Fries.; *Tubulifera*, Zopf.

#### ORDER 3. EXOSPOREA, Zopf.

**Characters.**—The chlamydospore liberates an amoeba in the first instance, which develops into a flagellula. This subsequently returns to the amoeba form, and by fusion with other amoebulae it forms a true fusion plasmodium. The spores are not produced within a cyst but upon the surface of column-like up-growths of the plasmodium, each spore (conidium) forming as a little spherical outgrowth attached to the column (conidiophore) by a distinct pedicle.

**Sole Genus.**—*Ceratium*. [This name must be changed, since it was already applied to a genus of Dinoflagellata, when Faminetzin and Woronin gave it to this Mycetozoon.]

**Further Remarks on Mycetozoa.**—About two hundred species of Mycetozoa have been described. Botanists, and especially those who occupy themselves with Fungi, have accumulated the very large

mass of facts now known in reference to these organisms; nevertheless the most eminent botanist who has done more than any other to advance our knowledge of Mycetozoa, namely, De Bary, has expressed the view that they are to be regarded rather as animals than as plants. The fact is that, once the question is raised, it becomes as reasonable to relegate all the Gymnomyxa without exception to the vegetable kingdom as to do so with the Mycetozoa. Whatever course we take with the latter, we must take also with the Heliozoa, the Radiolaria, and the Reticularia.

The formation of plasmodia, for which the Mycetozoa are conspicuous, appears to be a particular instance of the general phenomenon of cell-conjugation. Small plasmodia are formed by some of the Proteomyxa; but among the other Gymnomyxa, excepting Mycetozoa, and among Corticate Protozoa, the fusion of two individuals (conjugation *sensu stricto*) is more usual than the fusion of several. Zopf (13) has attempted to distinguish arbitrarily between conjugation and plasmodium formation by asserting that in the former the nuclei of the cells which fuse are also fused, whereas in the latter process the nuclei retain their independence. Both statements are questionable. What happens to the nucleus in such conjugations as those of the Gregarina has not yet been made out, whilst it is only quite recently that Strasburger (30) has shown that the plasmodia of Mycetozoa contain numerous scattered nuclei, and it is not known that fusion does not occur between some of these. There is no doubt that the nuclei of plasmodia multiply by fission, though we have no detailed account of the process.

The Sorophora are exceptional in that the amoeba which unite to form a cell-colony in their case do not actually fuse but only remain in close contact; with this goes the fact that there are no large spore-cysts, but an identification of spore and spore-cyst. The amoebae arrange themselves in stalked clusters (sori), and each becomes encysted: one may, in this case, consider the cyst equally as a spore or as a spore-cyst which produces but a single spore. The amoebae described by various writers as inhabiting the alimentary canal and the dung of higher animals (including man) belong to this group. The form described by Cunningham in the *Quart. Jour. Micr. Sci.*, 1881, as *Protomyxomyces coprinarius* is apparently related to the *Copromyxa* (*Guttulina*) *prolea* of Farol (31).

The spore-fruits of the Endosporea occur in various degrees of elaboration. Usually they are (1) spherical or pear-shaped cysts with or without an obvious stalk (Fig. III. 19, 20, 21), and often have a brilliant colour, and are of a size readily observed by the naked eye, the plasmodia which give rise to them being by no means microscopic. But they may present themselves (2) as irregular ridges growing up from the plasmodium, when they are termed serpulæ forms. Lastly, the cysts may be united side by side in larger or smaller groups instead of forming at various separate points of the plasmodium. These composite bodies are termed "fruit-cakes" or "æthalia," in view of the fact that the spore-cysts of *Fuligo*, also called *Æthaliium*—the well-known "flowers of tan"—form a cake of this description.

The capillitium or network of threads which lies between the spores in the spore-cysts of Endosporea is a remarkable structure which exhibits special elaborations in detail in different genera, here not to be noticed for want of space. Although definite in form and structure, these threads are not built up by cells but are formed by a residual protoplasm (*cf.* Sporozoa) which is left in the cyst after the spores have been segregated and enclosed each in its special coat. They are often impregnated by calcium carbonate, and exhibit crystalline masses of it, as does also the cyst-wall.

The spores of the Mycetozoa are as a rule about the  $\frac{1}{1000}$ th inch in diameter. They are produced by millions in the large fruit-cakes of such forms as *Fuligo*. Often the spore-coat is coloured; it always consists of a substance which gives the cellulose reaction with iodine and sulphuric acid. This has been sometimes considered an indication of the vegetable nature of the Mycetozoa, but cannot be so regarded since many animals (especially the Tunicata and various Protozoa) produce substances giving this same reaction.

Dryness, low temperature, and want of nutriment lead to a dormant condition of the protoplasm of the plasmodium of many Mycetozoa and to its enclosure in cyst-like growths known as "sclerotia," which do not give rise to spores, but from which the protoplasm creeps forth unaltered when temperature, nutrition, and moisture are again favourable. The sclerotia are similar in nature to the hypocysts of other Protozoa.

The physiological properties—chemical composition, digestive action, reaction to moisture, heat, light, and other physical influences—of the plasmodia of Mycetozoa have been made the subject of important investigations; they furnish the largest masses of undifferentiated protoplasm available for such study. The reader is referred to Zopf's admirable treatise (13) as to these matters, and also for a detailed account of the genera and species.

#### CLASS III. LOBOSA, Carpenter.

**Characters.**—Gymnomyxa in which (as in the succeeding four classes) the amoeba-phase predominates over the others in permanence, size attained, and physiological importance. The pseudo-

podia are lobose, ranging in form from mere wave-like bulgings of the surface to blunt finger-like processes, but never having the character of filaments either simple, arborescent, or reticulate. Fusions of two individuals (conjugation) have been observed in a

FIG. IV.—Various Lobosa. 1, 2, 3. *Dactylosphæra* (*Amœba*) *polypodia*, M. Schultze, in three successive stages of division; the changes indicated occupied fifteen minutes. *a*, nucleus; *b*, contractile vacuole (copied from F. E. Schultze, in *Archiv. Mikrosk. Anat.*). 4. *Amœba princeps*, Ehr. (after Auerbach). *a*, nucleus; *b*, *c*, vacuoles (one or more contractile; the shaded granules are food-particles). 5. *Pelomyxa palustris*, Greeff (after Greeff), an example with comparatively few food-particles (natural size  $\frac{1}{10}$ th inch in length). 6. Portion of a *Pelomyxa* more highly magnified. *a*, clear superficial zone of protoplasm (so-called "exoplasm"); *b*, vacuoles, extremely numerous; *c*, lobose pseudopodium; *d*, a similar pseudopodium; *e*, nuclei; *f*, "refractive bodies" (reproductive?); scattered about in the protoplasm are seen numerous cylindrical crystals. 7. *Arcella vulgaris*, Ehr. *a*, shell; *b*, protoplasm within the shell; *c*, extended protoplasm in the form of lobose pseudopodia; *d*, nuclei; *e*, contractile vacuole; the dark bodies unlettered are gas vacuoles. 8. *Cochliopodium pellucidum*, Hert. and Less. *a*, nucleus surrounded by a hyaline halo sometimes mistaken for the nucleus, whilst the latter is termed nucleolus.

few cases, but not fusions of many individuals so as to form plasmodia; nevertheless the size attained by the naked protoplasm by pure growth is in some cases considerable, forming masses readily visible by the naked eye (*Pelomyxa*). The presence of more than

one nucleus is a frequent character. A contractile vacuole may or may not be present. The formation of sporocysts and of chlamydo-spores (coated spores) has not been observed in any species, but naked spores (flagellulæ or amœbulæ) have been with more or less certainty observed as the product of the breaking up of some species (*Amœba*? *Pelomyxa*). The cyst phase is not unusual, but the cyst appears usually to be a hypnoeyst and not a sporocyst. In the best observed case of spore-production (*Pelomyxa*) the spores were apparently produced without the formation of a cyst. Reproduction is undoubtedly most freely effected by simple fission (*Amœba*) and by a modified kind of bud-fission (*Arcella*). Fresh-water and marine. Two orders of the Lobosa are distinguished in accordance with the presence or absence of a shell.

#### ORDER 1. NUDA.

*Characters*.—Lobosa devoid of a shell.

*Genera*.—*Amœba*, Auct. (Fig. IV. 4); *Ouramœba*, Leidy (with a villous tuft at one end, Wallich's *A. villosa*); *Corycia*, Duj. (low, ridge-like pseudopodia); *Lithamœba*, Lankester (Fig. V.); *Dinamœba*, Leidy (32) (covered with short stiff processes); *Hyalodiscus*, H. and L.; *Plakopus*, F. E. Schultze; *Dactylosphæra*, H. and L. (Fig. IV. 1, 2, 3); *Pelomyxa*, Greeff (Fig. IV. 5, 6); *Amphizonella*, Greeff (forms a gelatinous case which is broken through by the pseudopodia).

#### ORDER 2. TESTACEA.

*Characters*.—Lobosa which secrete a shell provided with an aperture from which the naked protoplasm can be protruded. The shell is either soft and membranous, or strengthened by the inclusion of sand-particles, or is hard and firm.

*Genera*.—*Cochliopodium* (Fig. IV. 8), H. and L.; *Pyxidicula*, Ehr.; *Arcella*, Ehr. (Fig. IV. 7); *Hyalosphenia*, Stein; *Quadrula*, F. E. Schultze (shell membranous, areolated); *Diffugia*, Leclerc (shell with adventitious particles).

*Further remarks on the Lobosa*.—The Lobosa do not form a very numerous nor a very natural assemblage. Undoubtedly some of the forms which have been described as species of *Amœba* are amœba forms of Mycetozoa; this appears to be most probably the case in parasitic and stercoricolous forms. But when these are removed, as also those *Proteomyxa* which have pseudopodia of varying character, at one time lobose and at another filamintous, we have left a certain small number of independent lobose *Gymnomyxa* which it is most convenient to associate in a separate group. We know very little of the production of spores (whether it actually obtains or not) or of developmental phases among these Lobosa. The common *Amœbæ* are referable to the species *A. princeps*, *A. lobosa*, *Dactylosphæra polypodia*, *Ouramœba villosa*. Of none of these do we know certainly any reproductive phenomena excepting that of fission (see Fig. IV. 1, 2, 3). Various statements have been made pointing to a peculiar change in the nucleus and a production of spores having the form of minute *Amœbæ*, arising from that body; but they cannot be considered as established. Whilst the observed cases of supposed reproductive phenomena are very few, it must be remembered that we have always to guard (as the history of the Ciliata has shown, see below) against the liability to mistake parasitic amœbulæ and flagellulæ for the young forms of organisms in which they are merely parasitic. The remarkable *Pelomyxa palustris* of Greeff (32) was seen by him to set free (without forming a cyst) a number of amœbulæ which he considers as probably its young. Mr Weldon of St John's College, Cambridge, has observed the same phenomenon in specimens of *Pelomyxa* which made their appearance in abundance in an aquarium in the Morphological Laboratory, Cambridge. It seems probable that the amœbulæ in this case are not parasites but spore-like young, and this is the best observed case of such reproduction as yet recorded in the group.

*Arcella* is remarkable for the production of bud-spores, which may be considered as a process intermediate between simple fission and the complete breaking up of the parent body into spores. As many as nine globular processes are simultaneously pinched off from the protoplasm extruded from the shell of the *Arcella*; the nuclei (present in the parent *Arcella* to the number of two or three) have not been traced in connexion with this process. The buds then become nipped off, and acquire a shell and a contractile vacuole (33).

The presence of more than one nucleus is not unusual in Lobosa and is not due to a fusion of two or more uninuclear individuals but to a multiplication of the original nucleus. This has been observed in some *Amœbæ* (*A. princeps*?) as well as in *Arcella* (*Arcella* (Fig. IV. 6) has a great number of nuclei like the zoön, *Actinosphaerium* (Fig. VIII.).

*Pelomyxa* is the most highly differentiated of the Lobosa. highly vacuolated character of its protoplasm is exhibited in degree by *Lithamœba* and resembles that of *Heliozoa* and *Radio*. Besides the numerous nuclei there are scattered in the protoplasm strongly refringent bodies (Fig. IV. 6, *f*), the significance of has not been ascertained. The superficial protoplasm is full of vacuoles, hyaline, and extremely mobile. Occasionally it

out into very short fine filaments. Scattered in the protoplasm are a number of minute cylindrical crystals, of unascertained composition. *Pelomyxa* is of very large size for a Protozoon, attaining a diameter of  $\frac{1}{16}$ th of an inch. It takes into its substance a quantity of foreign particles, both nutrient organic matter such as Rotifera and Diatoms and sand particles. It occurs not uncommonly in old

It has been observed to take in solid nourishment, though *Labyrinthula* has not.

The Labyrinthulidæ present strong resemblances to the Mycetozoa. The genus *Dactylostelium* (Sorophora) would come very close to *Labyrinthula* were the amœbæ of its aggregation plasmodium

FIG. V.—*Labyrinthula darwini*, Lank. (after Lankaster, 34). A, quiescent; B, contracting vacuole, overlying which the vacuolate protoplasm is seen; cone, concretions insoluble in dilute HCl and dilute KNO<sub>3</sub>, but soluble in strong HCl; n, nucleus.

muddy ponds (such as duck-ponds), creeping upon the bottom, and has a white appearance to the naked eye. *Lithamœba* (Fig. V.) is distinguished by its large size, disk-like form, the disk-like shape of its pseudopodia, the presence of specific concretions, the vacuolation of its protoplasm, and the block-like form and peculiar tessellated appearance of its large nucleus, which has a very definite capsule. In *Lithamœba* it is easy to recognize a distinct pellicle or temporary cuticle which is formed upon the surface of the protoplasm, and bursts when a pseudopodium is formed. In fact it is the rupture of this pellicle which appears to be the proximate cause of the outflow of protoplasm as a pseudopodium. Probably a still more delicate pellicle always forms on the surface of naked protoplasm, and in the way just indicated determines by its rupture the form and the direction of the "flow" of protoplasm which is described as the "protrusion" of a pseudopodium.

The shells of *Lobos* and *Tetras* are not very complex. That of *Arcebia* is remarkable for its hexagonal apertures, dark colour, and firm consistence; it consists of a substance resembling chitin. That of *Difflugia* has a delicate membranous basis, but includes foreign particles, so as to resemble the built-up case of a Caddis worm.

*Arcebia* is remarkable among all Protozoa for its power of secreting gas vacuoles (observed also in an *Amœba* by Butcherli), which serve a hydrostatic function, causing the *Arcebia* to float. The gas can be rapidly absorbed by the protoplasm, when the vacuole necessarily disappears and the *Arcebia* sinks.

#### CLASS IV. LABYRINTHULIDEA.

**Character.**—*Gymnomyxa* forming irregular heaps of ovoid nucleated cells, the protoplasm of which extends itself as a branching network or labyrinth of fine threads. The oval (spindle-shaped) corpuscles, consisting of dense protoplasm, and possessing each a well-marked nucleus (not observed in *Chlamydomyxa*), travel regularly and continuously along the network of filaments. The oval corpuscles multiply by fission; they also occasionally become encysted and divide into four spherical spores. The young forms developed from these spores presumably develop into colonies, but have not been observed.

**Genera.**—Two genera only of Labyrinthulidæ are known:—*Labyrinthula*, Cienkowski; *Chlamydomyxa*, Archer.

Cienkowski (35) discovered *Labyrinthula* on green Algae growing on wooden piles in the harbour of Odessa (marine). It has an orange colour and forms patches visible to the naked eye. *Chlamydomyxa* was discovered by Archer of Dublin (36) in the cells of *Sphagnum* and crawling on its surface; hence it is a freshwater form. Unlike *Labyrinthula*, the latter forms a laminated shell of cellulose (Fig. VI. 2, c), in which it is frequently completely enclosed, and indeed has rarely been seen in the expanded labyrinthine condition. The laminated cellulose shells are very freely secreted, the organism frequently detaching one and forming another within or adherent to that previously occupied. The network of *Chlamydomyxa* appears to consist of hyaline threads of streaming protoplasm, whilst that of *Labyrinthula* has a more horny consistence, and is not regarded by Cienkowski as protoplasm.

The spindle-shaped cells are much alike in form and size in the two genera; but no nucleus was detected by Archer in those of *Chlamydomyxa*. The encysting of the spindle-cells and their fission into spores has been seen only in *Labyrinthula*. *Chlamydomyxa* is often of a brilliant green colour owing to the presence of chlorophyll corpuscles, and may exhibit a red or mottled red and green appearance owing to the chemical change of the chlorophyll.

FIG. VI.—*Labyrinthula vitellina*, Cienk. 1. A colony of "cell-heaps" or "cell-heaps" of *Chlamydomyxa*, Archer, with fully expanded network of threads. 2. A colony of *L. vitellina*, Cienk., more highly magnified. 3. A portion of the network of *L. vitellina*, Cienk., more highly magnified. 4. A single spindle cell and threads of *L. vitellina*, Cienk. 5. A group of encysted cells of *L. macrocystis*, Cienk. 6. Encysted cells of *L. macrocystis*, with enclosed protoplasm divided into four spores. 7. Encysted cells of *L. macrocystis*, with enclosed protoplasm divided into four spores. 8. Transverse division of a non-encysted spindle-cell of *L. macrocystis*. 9. A portion of the general protoplasm detached and becoming encysted.

set upon a network of threads. Such a network, whether in the condition of soft protoplasm or hardened and horny, is represented in the higher Mycetozoa by the capillitium of the sporozysts.

The most important difference between Archer's *Chlamydomyxa* and Cienkowski's *Labyrinthula* is that in the former the threads

of the network appear to consist of contractile protoplasm, whilst in the latter they are described as firm horny threads exuded by the spindle-cells. Neither form has been re-examined since its discovery; and it is possible that this apparent difference will be removed by further study.

numerous isolated filamentous pseudopodia which exhibit very little movement or change of form, except when engaged in the inception of food-particles. The protoplasm of the spherical body is richly vacuolated; it may exhibit one or more contractile vacuoles and either a single central nucleus or many nuclei (Nuclearia, Actinosphaerium). Skeletal products may or may not be present. Flagellates have been observed as the young forms of some species (Acanthocystis, Clathrulina), but very little has been as yet ascertained as to spore-formation or conjugation in this group, though isolated facts of importance have been observed. Mostly freshwater forms.

FIG. VII.—Heliozoa. 1. *Actinophrys sol*, Ehrh.;  $\times 800$ . *a*, food-particle lying in a large food-vacuole; *b*, deep-lying finely granular protoplasm; *c*, axial filament of a pseudopodium extended inwards to the nucleus; *d*, the central nucleus; *e*, contractile vacuole; *f*, superficial much-vacuolated protoplasm. 2. *Clathrulina elegans*, Glenk.;  $\times 200$ . 3. *Heterophrys marina*, H. and L.;  $\times 660$ . *a*, nucleus; *b*, clearer protoplasm surrounding the nucleus; *c*, the peculiar felted envelope. 4. *Raphidiophrys pallida*, F. E. Schultze;  $\times 430$ . *a*, food-particle; *b*, the nucleus; *c*, contractile vacuole; *d*, central granule in which all the axis-filaments of the pseudopodia meet. The tangentially disposed spicules are seen arranged in masses on the surface. 5. *Acanthocystis turfacea*, Carter;  $\times 240$ . *a*, probably the central nucleus; *b*, clear protoplasm around the nucleus; *c*, more superficial protoplasm with vacuoles and chlorophyll corpuscles; *d*, coarser siliceous spicules; *e*, finer forked siliceous spicules; *f*, finely granular layer of protoplasm. The long pseudopodia reaching beyond the spicules are not lettered. 6. Bi-flagellate "flagellula" of *Acanthocystis aculeata*. *a*, nucleus. 7. Ditto of *Clathrulina elegans*. *a*, nucleus. 8. *Astrodisculus ruber*, Greeff;  $\times 320$ . *a*, red-coloured central sphere (? nucleus); *b*, peripheral homogeneous envelope.

#### CLASS V. HELIOZOA, Haeckel, 1866.

*Characters*.—Gymnomyxa in which the dominating amoeba phase has the form of a spherical body from the surface of which radiate

FIG. VIII.—Heliozoa. 1. *Actinosphaerium Eichhornii*, Ehrh.;  $\times 200$ . *a*, nuclei; *b*, deeper protoplasm with smaller vacuoles and numerous nuclei; *c*, contractile vacuoles; *d*, peripheral protoplasm with larger vacuoles. 2. A portion of the same specimen more highly magnified and seen in optical section. *a*, nuclei; *b*, deeper protoplasm (so-called endosarc); *d*, peripheral protoplasm (so-called ectosarc); *e*, pseudopodia showing the granular protoplasm streaming over the stiff axial filament; *f*, food-particle in a food-vacuole. 3, 4. Nuclei of *Actinosphaerium* in the particle in a food-vacuole. 5-13. Successive stages in the division of a nucleus of *Actinosphaerium*, showing fibrillation, and in 7 and 8 formation of an equatorial plate of chromatin substance (after Hertwig). 14. Cyst-phase of *Actinosphaerium Eichhornii*, showing the protoplasm divided into twelve chilamydospores, each of which has a siliceous coat; *a*, nucleus of the spore; *g*, gelatinous wall of the cyst; *h*, siliceous coat of the spore.

## ORDER 1. APHROTHORACA, Hartwig (56).

*Character.*—Helicon devoid of a spicular or gelatinous envelope, existing in some a temporary membranous cyst.

*Genera.*—*Nuclearia*, Grun. (37) (many nuclei; many contractile vacuoles; body not permanently spherical, but amoeboid); *Actinophrys*, Ehr. (Fig. VII. 1; body spherical; pseudopodia with an axial skeletal filament; central nucleus; one large contractile vacuole; often forming colonies; *A. sol.*, the Sun-animalcule); *Actinopharium*, Stein (Fig. VIII; spherical body; pseudopodia with axial filament; nuclei very numerous; contractile vacuoles 2 to 14); *Actinophrys*, F. E. Schulze (staked).

## ORDER 2. CHLAMYDOPHORA, Archer (57).

*Character.*—Helicon with a soft jelly-like or faked fibrous envelope.

*Genera.*—*Helophrys*, Archer (Fig. VII. 2); *Sphaerodrum*, Grun.; *Actinodrum*, Grun. (Fig. VII. 3).

## ORDER 3. CHALATHORACA, Hartw. and Less. (58).

*Character.*—Helicon with a loose envelope consisting of isolated siliceous spicules.

*Genera.*—*Raphidophrys*, Archer (Fig. VII. 4; skeleton in the form of numerous slightly curved spicules placed tangentially in the superficial protoplasm); *Pompiliophrys*, Archer; *Picocystis* H. and L.; *Picodictyon*, Grun.; *Acanthophrys*, Carter (skeleton in the form of radially disposed siliceous needles; encysted condition observed, and flagellulae young, Fig. VII. 6); *Wagnerella*, Menzies.

## ORDER 4. DESMOTHORACA, Hartw. and Less.

*Character.*—Helicon with a skeletal envelope in the form of a spherical or nearly spherical shell of silica perforated by numerous large holes.

*Genera.*—*Orbulina*, Ehr. (without a stalk); *Globulina*, Grun. (with a stalk, Fig. VII. 2).

*Further remarks on the Helicon.*—The Sun-animalcules, Actinophrys and Actinopharium, were the only known members of this group when Carter discovered in 1893 Acanthophrys. Our further knowledge of them is chiefly due to Archer of Dublin, who discovered the most important forms, and figured them in the *Quart. Jour. Micro. Sci.* in 1897.

Some of the Protozoa (e.g., *Vampyrella*) exhibit "Helicon-like" or "actinophryd" forms, but are separated from the true Helicon by the fact that their radiant pseudopodia are not maintained for long in the stiff isolated condition characteristic of this group. It is questionable whether *Nuclearia* should not be relegated to the Protozoa on account of the mobility of its body, which in all other Helicon has a constant spherical form.

*Actinophrys sol.* is often seen to form groups or colonies (by fission), and so also is *Raphidophrys*. It is probable from the little that is known that reproduction takes place not only by simple fission but by multiple fission, producing flagellate spores which may or may not be provided by encystment. Only *Globulina*, *Acanthophrys*, *Actinopharium*, and *Actinophrys* have been observed in the encysted state, and only the first two have been credited with the production of flagellated young. The two latter genera form covered spores within their cysts, those of *Actinopharium* being remarkable for their siliceous crusts (Fig. VIII. 14), but their further development has not been seen.

## CLASS VI. RETICULARIA, Carpenter, 1892.

(*Foraminifera*, Ann., *Thalamophora*, Hartwig).

*Character.*—Gymnamoeba in which the dominating amebic phase, often of great size (an inch in diameter), has an irregular form, and a tendency to throw out great trunks of branching and often anastomosing filamentous pseudopodia, and an equally strong tendency to form a shell of secreted membrane or secreted lime or of agglutinated sand particles (only in one genus of secreted silica) into which the protoplasm (not in all) can be drawn and one of and over which it usually streams in widely spreading lobes and branches. One nucleus is present, or there are many. A contractile vacuole is sometimes, but not as a rule, present (or at any rate not described). Reproduction is by fission and (as in some other Protozoa) by the formation of peculiar bud-spores which remain for a time after their formation embedded in the parental protoplasm. No multiple breaking up into spores after or independent of the formation of a cyst is known. Marine and freshwater.

The Reticularia are divisible into several orders. The marked peculiarity of the shell structure in certain of these orders is only fitly emphasized by grouping them together as a sub-class Perforata in contrast to which the remaining orders stand as a sub-class Imperforata. The distinction, however, is not an absolute one, for a few of the Lincolnia are perforate, that is, are sandy isomorphs of perforate genera such as *Globigerina* and *Buccella*.

FIG. II.—Gromiidea (*Reticularia membranosa*). 1. *Diphyphy* Archer, Euker. a, nucleus; b, contractile vacuole; c, the yellow cell-like body. Moor pool, Ireland. 2. *Gromia californica*, Dy. a, the numerous nuclei; near these the elongated bodies represent thrust-out pseudopodia. Freshwater. 3. *Strophodonta tenuiformis*, Sjöhall (*Quart. Jour. Micro. Sci.*, 1890);  $\times 30$  diameter. Marine. The protoplasm is retracted at both ends into the tubular case. a, nucleus. 4. *Strophodonta tenuiformis*;  $\times 15$ ; with pseudopodia fully expanded. 5-10. Varying appearance of the nucleus as it is carried along in the streaming protoplasm within the tube. 11. *Amphirema Wrighti*, Archer, showing membranous shell encased with foreign particles. Moor pool, Ireland. 12. *Diaphanophrys sol*, Archer. a, nucleus. Moor pool, Ireland.

## SUB-CLASS A. Imperforata.

*Character.*—Shell substance not perforated by numerous apertures through which the protoplasm can issue, but provided with only one or two large apertures, or in branched forms with a few such apertures.

## ORDER I. GROMIDEA, Brady.

*Character.*—Shell or test membranous, in the form of a simple sac with a pseudopodial aperture either at one extremity or at both. Pseudopodia thread-like, long, branching, reticulated. Marine and freshwater.

Fam. 1. *Monostomina*, with a single aperture to the shell.

Genera.—*Lieberkuhnia*, Clap. and Lach.; *Gromia*, Duj. (Fig. IX. 2); *Mikrogonia*, Hertw.; *Euglypha*, Duj. (shell built up of hexagonal siliceous plates); *Diaphorophodon*, Archer (38) (many foreign particles cemented to form shell; small pseudopodia issue between these, hence resembling Perforata, and large long ones from the proper mouth of the shell, Fig. IX. 12).

FIG. X.—Imperforata. 1. *Spiroculina planulata*, Lamarck, showing five "colls"; porcellaneous. 2. Young ditto, with shell dissolved and protoplasm stained so as to show the seven nuclei n. 3. *Spirolina* (*Pencroplis*); a sculptured imperfectly coiled shell; porcellaneous. 4. *Vertebraalina*, a simple shell consisting of chambers succeeding one another in a straight line; porcellaneous. 5. 6. *Thurammina papillata*, Brady, a sandy form. 5 is broken open so as to show an inner chamber; recent. x 25. 7. *Lituola* (*Diaphorophagium*) *canariensis*, a sandy form; recent. 8. Nucleated reproductive bodies (bud-spores) of *Haliphysema*. 9. *Squamulina levis*, M. Schultze; x 40; a simple porcellaneous Miliolide. 10. Protoplasmic core removed after treatment with weak chromic acid from the shell of *Haliphysema Tumanovitzii*, Bow. n, vesicular nuclei, stained with hematoxylin (after Lankester). 11. *Haliphysema Tumanovitzii*; x 25 diam.; living specimen, showing the shell built up of sand-grains and sponge-spicules, and p, issuing from the mouth of the shell and projecting constituents. 12. Shell of *Astrothe* rays usually broken away in preserved specimens (original). 13. Section of the shell of *Marsipella*, showing thick walls built of sand-grains.

Fam. 2. AMPHISTOMINA, with an aperture at each end of the shell. Genera.—*Diplophrys*, Barker (Fig. IX. 1); *Ditrema*, Archer; *Amphitrema*, Archer (Fig. IX. 11); *Shephardella*, Siddall (39) (membranous shell very long and cylindrical so as to be actually tubular, narrowed to a spout at each end, Fig. IX. 8; protoplasm extended from either aperture, Fig. IX. 5, and rapidly circulating within the tubular test during life, carrying with it the nucleus which itself exhibits peculiar movements of rotation, Fig. IX. 6, 7, 8, 9, 10).

## ORDER 2. ASTORRHIZIDEA, Brady.

**Characters.**—Test invariably consisting of foreign particles; it is usually of large size and single-chambered, often branched or radiate with a pseudopodial aperture to each branch, the test often continued on to the finer branches of the pseudopodia (Fig. X. 12); never symmetrical. All marine.

Fam. 1. ASTORRHIZINA, Brady. Walls thick, composed of loose sand or mud very slightly cemented.

Genera.—*Astorrhiza*, Sandahl (Fig. X. 12, very little enlarged); *Pelosina*, Brady; *Storthosphæra*, Brady; *Dendrophrya*, St. Wright; *Syringamina*, Brady.

Fam. 2. PILULININA. Test single-chambered; walls thick, composed chiefly of felted sponge-spicules and fine sand, without calcareous or other cement.

Genera.—*Pilulina*, Carpenter; *Techmitella*, Norman; *Bathysiphon*, Sars.

Fam. 3. SACCAMMININA. Chambers nearly spherical; walls thin, composed of firmly cemented sand grains.

Genera.—*Psanmosphæra*, Schultze; *Sorosphæra*, Brady; *Saccamina*, M. Sars.

Fam. 4. RHARDAMMININA. Test composed of firmly cemented sand-grains, often with sponge-spicules intermixed; tubular; straight, radiate, branched or irregular; free or adherent; with one, two, or more apertures; rarely segmented.

Genera.—*Jaculilla*, Brady; *Marsipella*, Norman (Fig. X. 13); *Rhabdammina*, M. Sars; *Aschemonella*, Brady; *Rhizamina*, Brady; *Sagenella*, Brady; *Botellina*, Carp.; *Haliphysema*, Bowerbank (test wine-glass-shaped, rarely branched, attached by a disk-like base; generally beset with sponge-spicules, Fig. X. 11; pseudopodial aperture at the free extremity). This and *Astorrhiza* are the only members of this order in which the living protoplasm has been observed; in the latter it has the appearance of a yellowish cream, and its microscopic structure is imperfectly unknown (61). In *Haliphysema* the network of expanded pseudopodia has been observed by Saville Kent as drawn in Fig. X. 11. Lankester (59) discovered numerous vesicular nuclei scattered in the protoplasm (Fig. X. 10, n), and also near the mouth of the shell reproductive bodies (probably bud-spores) embedded in the protoplasm (Fig. X. 8). *Haliphysema* was described by Bowerbank as a Sponge, and mistaken by Haeckel (60) for a very simple two-cell-layered animal (*Enterozoon*), to which he assigned the class name of *Physcmaria*.

## ORDER 3. MILIOLIDEA, Brady.

**Characters.**—Test imperforate; normally calcareous and porcellaneous, sometimes encrusted with sand; under starved conditions (e.g. in brackish water) becoming chitinous or chitino-arenaceous; at abyssal depths occasionally consisting of a thin homogeneous, imperforate, siliceous film. The test has usually a chambered structure, being divided by septa (each with a hole in it) into a series of loculi which may follow one another in a straight line (Fig. X. 4) or the series may be variously coiled (Fig. X. 1 and 3). The chambering of the test does not express a corresponding cell-segmentation of the protoplasm; the latter, although growing in volume as the new shell-chambers are formed, remains one continuous cell-unit with many irregularly scattered nuclei (Fig. X. 2). The chambered and septate structure results in this group and in the other orders from the fact that the protoplasm, expanded beyond the last-formed chamber, forms a new test upon itself whilst it lies and rests upon the surface of the old test. The variations in such a formation are shown in Fig. XII. 1, 2, 3, 4.

Fam. 1. NUBECULARINA. Test free or adherent, taking various irregular asymmetrical forms, with variable aperture or apertures.

Genera.—*Squamulina*, Schultze (Fig. X. 9, showing the expanded pseudopodia); *Nubecularia*, Defrance.

Fam. 2. MILIOLINA. Shell coiled on an elongated axis, either symmetrically or in a single plane or inequilaterally; two chambers in each convolution. Shell aperture alternately during growth (addition of new chambers) at either end of the shell.

Genera.—*Biloculina*, D'Orb.; *Fabularia*, Defrance; *Spiroculina*, D'Orb. (Fig. X. 1, 2); *Miliolina*, Williamson (Fig. XI.).

Fam. 3. HAUSERININA. Shell dimorphous; chambers partly milioline, partly spiral or rectilinear.

Genera.—*Articulina*, D'Orb.; *Vertebraalina*, D'Orb. (Fig. X. 4); *Ophthalmidium*, Kubler; *Haucrina*, D'Orb.; *Planispirina*, Seguenza.

Fam. 4. PENEROPLIDINA. Shell planospiral or eyelical, sometimes erosier-shaped, bilaterally symmetrical.

Genera.—*Cornuspira*, Schultze; *Peneroplis*, Montfort (Fig. X. 3);

*Orbiculina*, Lamarek; *Orbitolites*, Lamarek (by a division of the chambers regularly into chamberlets, and a cyclical mode of growth which results in shells of the size of a shilling, a very elaborate-looking structure is produced which has been admirably analysed by Carpenter (40), to whose memoir the reader is specially referred).

FIG. XI.—*Miliolina (Triloculina) tenera*. Young living animal with expanded pseudopodia (after Max Schultze). A single nucleus is seen in the innermost chamber.

Fam. 5. *ALYFOLIXINA*. Shell spiral, elongated in the line of the axis of the convolution; chambers divided into chamberlets.

Genus.—*Alveolina*, D'Orb.

Gen. 6. KERAMOPHRINA: Shell spherical; chambers in concentric layers.

Genus.—*Keramospharra*, Brady.

ORDER 4. LITUOLIDEA, Brady.

*Characters.*—Test arcuneous, usually regular in contour; septation of the many-chambered forms often imperfect, the cavity being labyrinthic. This order consists of sandy isomorphs of the simpler Miliolidea, and also of the simpler Perforata (*Lagena*, *Nodosaria*, *Cristellaria*, *Globigerina*, *Rotalia*, *Nonionina*, &c.); it also contains some peculiar adherent species.

Fam. 1. *LITVOLISA*. Test composed of coarse sand-grains, rough externally; often labyrinthic.

Genera.—*Reophax*, Montfort; *Haplophragmium*, Reuss (Fig. X. 7); *Coskiolina*, Stache; *Placopsilina*, D'Orb.; *Haplostiche*, Reuss; *Lituola*, Lamarck; *Bdelloidina*, Carter.

Fam. 2. TROCHAMMININA. Test thin, composed of minute sand-grains incorporated with calcareous and other organic cement, or embedded in a chitinous membrane; exterior smooth, often polished; interior smooth or rarely reticulated; never labyrinthic.

Genera.—*Thurammina*, Brady (test consisting typically of a single spherical chamber with several mammillate apertures, Fig. X. 5, 6); *Hippocrepina*, Parker; *Hormosina*, Brady; *Ammodiscus*, Reuss; *Trochammina*, Parker and Jones; *Cartertina*, Brady; *Webbina*, D'Orb.

Fam. 3. **ENDOTHRINA.** Test more calcareous and less sandy than in the other groups of Litulidae; sometimes perforate; sensation distinct.

Genera.—*Nodosinella*, Brady; *Polyphragma*, Reuss; *Involutina*, Tera.; *Endothyra*, Phillips; *Bradyina*, Moll.; *Stachcia*, Brady.

**Fam. 4. LOFTUSINA.** Test of relatively large size; lenticular, spherical, or fusiform; constructed either on a spiral plan or in concentric layers, the chamber cavities occupied to a large extent by the excessive development of the finely arenaceous cancellated walls.

Genera.—*Cyclammina*, Brady; *Loftusia*, Brady; *Parkeria*, Carpenter.

**SUB-CLASS B. Perforata.**

*Characters.*—Shell substance perforated by numerous minute apertures, through which as well as from the main aperture the protoplasm can issue.

ORDER 5. TEXTULARIDEA, Brady.

*Characters.*—Tests of the larger species arenaceous, either with or without a perforate calcareous basis; smaller forms hyaline and conspicuously perforated. Chambers arranged in two or more alternating series, or spiral or confused; often dimorphous.

Fam. 1. TEXTULARINA. Typically bi- or tri-serial; often bi-rarely tri-morphous.

Genera.—*Textularia* DeFrance; *Cuneolina*, D'Orb.; *Verniculina*, D'Orb.; *Tritaxia*, Reuss; *Chrysalidina*, D'Orb.; *Bigenerina*, D'Orb.; *Pavonina*, D'Orb.; *Spiroplecta*, Ehr.; *Gaudryina*, D'Orb.; *Valvulina*, D'Orb.; *Clavulina*, D'Orb.

Fam. 2. **BULIMININA**. Typically spiral; weaker forms more or less regularly biserial; aperture oblique, comma-shaped or some modification of that form.

Genera.—*Bulimina*, D'Orb.; *Virgulina*, D'Orb.; *Bifarina*, Parker and Jones; *Bolivina*, D'Orb.; *Pleurostomella*, Reuss.

Enm. 3. *CASSIDULINA*. Test consisting of a Textularia-like series of " " " " more or less coiled upon itself.

D'Orb.; *Ehrenbergina*, Reuss.

ORDER 6. CHILOSTOMELLIDEA, Brady.

*Characters*.—Test calcareous, finely perforate, many-chambered. Segments following each other from the same end of the long axis, or alternately at the two ends, or in cycles of three, more or less embracing. Aperture a curved slit at the end or margin of the final segment.

Genera.—*Ellipsoidina*, Seguenza; *Chilostomella*, Reuss; *Allo-*  
*morphina*, Reuss.

**ORDER 7. LAGENIDEA, Brady.**

*Characters*.—Test calcareous, very finely perforated; either single-chambered, or consisting of a number of chambers joined in a straight, curved, spiral, alternating, or (rarely) branching series. Aperture simple or radiate, terminal. No interseptal skeleton nor canal system.

Fam. 1. LAGENINA. Shell single-chambered.

Genera.—*Laguna*, Walker and Boys; *Nodosaria*, Lamk.; *Lingulina*, D'Orb.; *Frondicularia*, Defrance; *Rhabdopogonium*, Reuss; *Marginalina*, D'Orb.; *Paginulina*, D'Orb.; *Rimulina*, D'Orb.; *Cristellaria*, Lamk.; *Amphicoryne*, Schlumb.; *Lingulinopsis*, Reuss; *Flabellina*, D'Orb.; *Amphinorphina*, Neugeb.; *Dentalinopsis*, Reuss.

Fam. 2. POLYMORPHININA. Segments arranged spirally or irregularly around the long axis; rarely biserial and alternate.

Genera.—*Polymorphina*, D'Orb.; *Dimorphina*, D'Orb.; *Uvigerina*, D'Orb.; *Sagrina*, P. and J.

Fam. 3. RAMULININA. Shell branching, composed of spherical or pyriform chambers connected by long stoloniferous tubes.

Genus.—*Namulina*, Rupert Jones.

**ORDER 8. GLOBIGERINIDEA, Brady.**

*Characters*.—Test free, calcareous, perforate; chambers few, inflated, arranged spirally; aperture single or multiple, conspicuous. No supplementary skeleton nor canal system. All the larger species pelagic in habit.

Genera.—*Globigerina*, D'Orb. (Fig. XII. 6); *Orbulina*, D'Orb (Fig. XII. 6); *Hastigerina*, Wy. Thomson (Fig. XII. 5); *Pul-  
lenia*, P. and J.; *Sphaeroidina*, D'Orb.; *Candeina*, D'Orb.

ORDER 9. ROTALIDEA, Brady.

*Characters.*—Test calcareous, perforate; free or adherent. Typically spiral and "rotaliform" (Fig. XII. 2), that is to say, coiled in such a manner that the whole of the segments are visible on the superior surface, those of the last convolution only on the inferior or apertural side, sometimes one face being more convex sometimes the other. Aberrant forms evolute, outspread, acervuline, or irregular. Some of the higher modifications with double chamber-walls, supplemental skeleton, and a system of canals. The nature of this supplemental skeleton is shown in Fig. XII. 2 and 10.

Fam. 1. SPIRILLINIA. Test a complanate, planospiral, non-septate tube; free or attached.

Genus.—*Spirillina*, Ehr.

Fam. 2. *ROTALINA*. Test spiral, rotaliform, rarely evolute, very rarely irregular or acervulina.

Genera.—*Patellina*, Williamson; *Cymbalopera*, Hay; *Discorbina*, P. and J.; *Planorbulina*, D'Orb.; *Truncatulina*, D'Orb.; *Anomalina*, P. and J.; *Carpenteria*, Gray (adherent); *Rupertia*, Wallick; *Pulvinulina*, P. and J.; *Rotalia*, Lamk.; *Calcarina*, D'Orb. [Shell rotaliform; periphery furnished with radiating spines; supplemental skeleton and canal system largely developed. This form is shown in a dissected condition in Fig. XII. 10. Outside and between the successive chambers with finely perforated walls  $a^2$ ,  $a^3$ ,  $a^4$  a secondary shell-substance is deposited by the protoplasm which has a different structure. Whilst the successive chambers with their finely perforate walls (resembling dentine in structure) are formed by the mass of protoplasm issuing from the mouth of the last-formed chamber, the secondary or supplemental-shell substance is formed by the protoplasm which issues through the fine perforations of the primary shell substance; it is not finely canalienlated, but is of denser substance than the primary shell and traversed by coarse canals (occupied by the protoplasm) which make their way to the surface of the test ( $c$ ,  $c'$ ). In *Calcarina* a large bulk of this secondary shell substance is deposited around each chamber and also forms the heavy club-like spines.]

Fam. 3. TINOPORINA. Test consisting of irregularly heaped chambers with (or sometimes without) a more or less distinctly spiral primordial portion; for the most part without any general pseudopodial aperture.

Genera.—*Tinoporos*, Carpenter; *Gypsina*, Carter; *Aphrosina*, Carter; *Thalamopora*, Roemer; *Polytrema*, Risso. [Shell parasitic, encrusting, or arborescent; surface areolated, coloured pink or white, Fig. XII. 9. Interior partly occupied by small chambers, arranged in more or less regular layers, and partly by non-segmented canal-like spaces, often crowded with sponge-spicules. No true canal system. This is one of the most important types as exhibiting the arborescent and encrusting form of growth. It is fairly abundant.]

FIG. XII.—Perforata. 1. Spiral arrangement of simple chambers of a Reticularian shell. 2. Ditto, with double septal walls, and supplemental shell-substance (shaded). 3. Diagram to show the mode in which successively-formed chambers may completely embrace their predecessors. 4. Diagram of a simple straight series of non-embracing chambers. 5. *Hastigerina* (*Globigerina*) *Murrayi*, Wv. Thomson. a, bubbly (vacuolated) protoplasm, enclosing b, the perforated *Globigerina*-like shell (conf. central capsule of Radiolaria). From the peripheral protoplasm project, not only fine pseudopodia, but hollow spines of calcareous matter, which are set on the shell, and have an axis of active protoplasm. Pelagic; drawn in the living state. 6. *Globigerina bulloides*, D'Orb., showing the punctiform perforations of the shell and the main aperture. 7. Fragment of the shell of *Globigerina*, seen from within, and highly magnified. a, fine perforations in the inner shell substance; b, outer (secondary) shell substance. Two coarser perforations are seen in section, and one lying among the smaller. 8. *Orbulina uncinata*, D'Orb. Pelagic example, with adherent radiating

calcareous spines (hollow), and internally a small *Globigerina* shell. It is uncertain whether *Orbulina* is merely a developmental phase of *Globigerina*. a, *Orbulina* shell; b, *Globigerina* shell. 9. *Polytrema miniatum*, Lin.; x 12. Mediterranean. Example of a branched adherent calcareous perforate Reticularian. 10. *Calcarina Spengleri*, Gmel.; x 10. Tertiary, Sicily. Shell dissected so as to show the spiral arrangement of the chambers, and the copious secondary shell substance. a², a³, a⁴, chambers of three successive coils in section, showing the thin primary wall (finely tubulate) of each; b, b, b, perforate surfaces of the primary wall of four tiers of chambers, from which the secondary shell substance has been cleared away; c, c, secondary or intermediate shell substance in section, showing coarse canals; d, section of secondary shell substance at right angles to c'; e, tubercles of secondary shell substance on the surface; f, f, club-like processes of secondary shell substance.

#### ORDER 10. NUMMULINIDEA, Brady.

**Characters.**—Test calcareous and finely tubulated; typically free, many-chambered, and symmetrically spiral. The higher modifications all possess a supplemental skeleton, and canal system of greater or less complexity.

**Fam. 1. FUSULININA.** Shell bilaterally symmetrical; chambers extending from pole to pole; each convolution completely enclosing the previous whorls. Shell-wall finely tubulated. Septa single or rarely double; no true interseptal canals. Aperture a single elongated slit, or a row of small rounded pores, at the inner edge of the final segment.

Genera.—*Fusulina*, Fischer; *Schwagerina*, Möller.

**Fam. 2. POLYSTOMELLINA.** Shell bilaterally symmetrical, nautiloid. Lower forms without supplemental skeleton or interseptal canals; higher types with canals opening at regular intervals along the external septal depressions.

Genera.—*Nontontina*, D'Orb.; *Polystomella*, Lamarck.

**Fam. 3. NUMMULITINA.** Shell lenticular or ocomplanate; lower forms with thickened and finely tubulated shell-wall, but no intermediate skeleton; higher forms with interseptal skeleton and complex canal system.

Genera.—*Archæodiscus*, Brady; *Amphistegina*, D'Orb.; *Operculina*, D'Orb.; *Heterostegina*, D'Orb.; *Nummulites*, Lamarck; *Assilina*, D'Orb.

**Fam. 4. CYCLOCLYPEINA.** Shell complanate, with thickened centre, or lenticular; consisting of a disk of chambers arranged in concentric annuli, with more or less lateral thickening of laminated shell substance, or acervuline layers of chamberlets. Septa double and furnished with a system of interseptal canals.

Genera.—*Cycloclypeus*, Carpenter; *Orbitoides*, D'Orb.

**Fam. 5. EOOZONINA.** Test forming irregular, adherent, acervuline masses.

Genus.—*Eozoon* Dawson.

**Further remarks on the Reticularia.**—The name *Thalamophora*, pointing to the peculiar tendency which the larger members of the group have to form chamber after chamber and so to build up a complex shell, has been proposed by Hertwig (56) and adopted by many writers. The old name *Foraminifera* (which did not refer to the fine perforations of the Perforata but to the large pseudopodial aperture leading from chamber to chamber) has also been extended by some so as to include the simpler *Gromia*-like forms. On the whole Carpenter's term *Reticularia* (62) seems most suitable for the group, since they all present the character indicated. It has been objected that the Radiolaria are also reticular in their pseudopodia, but if we except the pelagic forms of *Reticularia* (*Globigerina*, *Orbulina*, &c.), we find that the Radiolaria are really distinguishable by their stiffer, straighter, radiating pseudopodia. No doubt the Labyrinthid *Chlamydomyxa* and the plasmodia of some Mycetozoa are as reticular in their pseudopodia as the *Reticularia*, but they possess other distinctive features which serve, at any rate in an artificial system, to separate them.

The protoplasm of the majority of the *Reticularia* is unknown, or only very superficially observed; hence we have made a point of introducing among our figures as many as possible which show this essential part of the organism. It is only recently (1876) that nuclei have been detected in the calcareous-shelled members of the group, and they have only been seen in a few cases.

The protoplasm of the larger shell-making forms is known to be often strongly coloured, opaque, and creamy, but its minute structure remains for future investigation. Referring the reader to the figures and their explanation, we would draw especial attention to the structure of the protoplasmic body of *Hastigerina* (one of the *Globigerinidae*) as detected by the "Challenger" naturalists. It will be seen from Fig. XII. 5 that the protoplasm extends as a relatively enormous "bubbly" mass around the shell which is sunk within it; from the surface of this "bubbly" (vacuolated or alveolated) mass the pseudopodia radiate.

The reader is requested to compare this with Fig. XIII., representing the "bubbly" protoplasmic body of *Thalassicola*. It then becomes obvious that the perforated central capsule CK of the latter holds the same relation to the mass of the protoplasm as does the central perforated shell of *Globigerina* (*Hastigerina*). The extreme vacuolation of the protoplasm in both cases (the vacuoles being

filled with sea-water accumulated by eudsmosis) and the stiff radiating pseudopodia are directly correlated with the floating pelagic life of the two organisms. All the Radiolaria are pelagic, and many exhibit this vacuolation; only a few of the Reticularia are so, and their structural correlation to that habit has only lately been ascertained.

The Reticularia are almost exclusively known by their shells, which offer a most interesting field for study on account of the very great complexity of form attained by some of them, notwithstanding the fact that the animal which produces them is a simple unicellular Protozoan. Space does not permit the exposition here of the results obtained by Carpenter in the study of the complex shells of Orbitolites, Operculina, Nummulites, &c.; it is essential that his work *Introduction to the Study of the Foraminifera* (Ray Society, 1862) should be consulted, and in reference to the sandy-shelled forms the monograph by Brady, in the *Challenger Reports*, vol. ix., 1883; and it must be sufficient here to point out the general principles of the shell-architecture of the Reticularia. Let us suppose that we have an ever-growing protoplasmic body which tends to produce a calcareous shell on its surface, leaving an aperture for the exit of its pseudopodia. It will grow too large for its shell and accumulate outside the shell. The accumulated external mass may then secrete a second chamber, resting on the first as chamber 1 rests on chamber 0 in Fig. XII. 4. By further growth a new chamber is necessitated, and so is produced a series following one another in a straight line, each chamber communicating with the newer one in front of it by the narrow pseudopodial aperture ( $a, a^1, a^2, a^3$ ). Now it is possible for these chambers to be very variously arranged instead of simply as in Fig. XII. 4. For instance, each new chamber may completely enclose the last, as in Fig. XII. 3, supposing the protoplasm to spread all over the outside of the old chamber before making a new deposit. Again the chambers need not succeed one another in a straight line, but may be disposed in a spiral (Fig. XII. 1). And this spiral may be a flat coil, or it may be a helicine spiral with a rising axis; further it may be close or open. All these forms in various degrees of elaboration are exhibited by Miliolidea and various Perforata.

But the Perforata in virtue of their perforate shell-walls introduce a new complication. The protoplasm issues not only from the mouth of the last-formed chamber, but from the numerous pores in the wall itself. This latter protoplasm exerts its lime-secreting functions; it gathers itself into coarse branching threads which remain uncalcified, whilst all around a dense deposit of secondary or supplemental shell-substance is thrown down, thus producing a coarsely canalicular structure. The thickness and amount of this secondary shell and the position it may occupy between and around the chambers of primitive shell-substance vary necessarily in different genera according to the mode in which the primitive chambers are arranged and connected with one another. Calcarina is a fairly typical instance of an abundant secondary shell-deposit (Fig. XII. 10), and it is the existence of structure resembling the chambers of Calcarina with their surrounding primary and secondary shell-substances which has rendered it necessary to regard Eozoon (41) as the metamorphosed encrusting shell of a pre-Cambrian Reticularian.

The division of the Reticularia into Imperforata and Perforata which is here maintained has no longer the significance which was once attributed to it. It appears, according to the researches of Brady, that it is not possible to draw a sharp line between these sub-classes, since there are sandy forms which it is difficult to separate from imperforate Lituolidea and are nevertheless perforate, in fact are "sandy isomorphs of Lagenas, Nodosaria, Globigerina, and Rotalia." It does not appear to the present writer that there can be any insurmountable difficulty in separating the Lituolidea into two groups—those which are sandy isomorphs of the porcelainous Miliolidea, and those which are sandy isomorphs of the hyaline Perforata. The two groups of Lituolidea thus formed might be placed in their natural association respectively with the Imperforata and the Perforata.

The attempt to do this has not been made here, but the classification of Brady has been adopted. In Bütschli's large work on the Protozoa (9) the breaking up of the Lituolidea is carried out to a logical conclusion, and its members dispersed among the Miliolidea on the one hand and the various orders of Perforata on the other hand.

The calcareous shell-substance of the Miliolidea being opaque and white has led to their being called "Porcellana," whilst the transparent calcareous shells of the smaller Perforata has gained for that group the synonym of "Hyalina."

The shells of the calcareous Reticularia and of some of the larger arenaceous forms are found in stratified rocks, from the Palæozoic strata onwards. The Chalk is in places largely composed of their shells, and the Eocene Nummulitic limestone is mainly a cemented mass of the shells of Nummulites often as large each as a shilling. The Atlantic ooze is a chalky deposit consisting largely of the shells of Globigerina, &c.

#### CLASS VII. RADIOLARIA, Haeckel, 1862 (63) (*Polycystina*, Ehr.).

*Characters*.—Gymnomyxa in which the protoplasmic body of the dominant amœba phase has the form of a sphere or cone from

the surface of which radiate filamentous pseudopodia, occasionally anastomosing, and encloses a spherical (homaxonic) or cone-shaped (monaxonic) perforated shell of membranous consistence known as the central capsule, and probably homologous with the perforated shell of a Globigerina. The protoplasm within the capsule (intracapsular protoplasm) is continuous through the pores or apertures of the capsule with the outer protoplasm. Embedded in the former lies the large and specialized nucleus (one or more). Gelatinous substance is frequently formed peripherally by the extracapsular protoplasm, constituting a kind of soft mantle which is penetrated by the pseudopodia. A contractile vacuole is never present.

Usually an abundant skeleton, consisting of spicules of silica or of a peculiar substance called acanthin arranged radially or tangentially, loose or united into a basket-work, is present. Oil globules, pigment, and crystals are found in greater or less abundance in the protoplasm.

In most but not all Radiolaria peculiar nucleated yellow corpuscles are abundantly present, usually regarded as parasitic Alga. Reproduction by fission has been observed, and also in some few species a peculiar formation of swarm-spores (flagellulae) within the central capsule, in which the nucleus takes an important part. All the Radiolaria are marine. The Radiolaria are divided into two sub-classes according to the chemical nature of their spicular skeleton, and into orders according to the nature and the disposition of the apertures in the wall of the central capsule.

FIG. XIII.—*Thalassicolla pelagica*, Haeckel;  $\times 25$ . CK, central capsule; EP, extracapsular protoplasm; al, alveoli, liquid-holding vacuoles in the protoplasm similar to those of Heliozoa, Pelomyxa, Hastigerina, &c.; ps, pseudopodia. The minute unlettered dots are the "yellow cells."

#### SUB-CLASS I. Silico-Skeleta, Lankester.

*Characters*.—A more or less elaborate basket-work of tangential and radial elements consisting of secreted silica is present; in rare exceptions no skeleton is developed.

#### ORDER 1. PERIPYLÆA, Hertwig.

*Characters*.—Silico-skeletal Radiolaria in which the central capsule is uniformly perforated all over by fine pore-canal; its form is that of a sphere (homaxonic), and to this form the siliceous skeleton primarily conforms, though it may become discoid, rhomboid, or irregular. The nucleus is usually single, but numerous nuclei are present in each central capsule of the Polycyttaria.

Fam. 1. SPHERIDA, Haeck. Spherical Peripylæa with a spherical basket-work skeleton, sometimes surrounded by a spongy outer skeleton, sometimes simple, sometimes composed of many concentric spheres (never discoid, flattened, or irregular). The central capsule sometimes encloses a part of the spherical skeleton, and often is penetrated by radiating elements.

Genera (selected).—*Elhmospæra*, Haeck.; *Xiphospæra*, Haeck.; *Staurospæra*, Haeck.; *Heliospæra*, Haeck. (Fig. XIV. 14); *Astromma*, Haeck.; *Haliomma*, Haeck.; *Actinomma*, Haeck. (Fig. XIV. 17; note the sphere within sphere, the smallest lying in the nucleus, and the whole series of spherical shells connected by radial spines); *Arachnospæra*, Haeck.; *Plegmospæra*, Haeck.; *Spongospæra*, Haeck. (Fig. XVI. 8).

Fam. 2. DISCIDA, Haeck. Discoid Peripylæa; both skeleton and central capsule flattened.

Genera (selected).—*Phæodiscus*, Haeck.; *Heliodiscus*, Haeck.; *Spongodiscus*, Haeck.; *Spongurus*, Haeck.

Fam. 3. THALASSICOLLIDA. Peripylæa devoid of a skeleton, or with a skeleton composed of loose siliceous spicules only. Nucleus single; central capsule and general protoplasm spherical.

Genera (selected).—*Thalassicolla*, Huxley (Fig. XIII, Fig. XIV. 1); *Thalassosphæra*, Haeck.; *Physematium*, Haeck.

Fam. 4. POLYCYTTARIA. Peripylæa consisting of colonies of many central capsules united by their extracapsular protoplasm. Central capsules multiplying by fission. Nuclei in each central capsule numerous. Siliceous skeleton either absent, or of loose spicules, or having the form of a spherical fenestrated shell surrounding each central capsule.

Genera (selected).—*Collosphæra*, Müller (with fenestrated globular skeleton); *Sphærozoum*, Haeck. (skeleton of numerous loose spicules which are branched); *Raphidozoum*, Haeck. (spicules simple); *Collozoum*, Müller (devoid of skeleton, Fig. XIV. 2, 3, 4, 5).

FIG. XIV.—Radiolaria. 1. Central capsule of *Thalassicolla nucleata*, Huxley, in radial section. *a*, the large nucleus (Binnenbläschen); *b*, corpuscular structures of the intracapsular protoplasm containing concretion; *c*, wall of the capsule (membranous shell), showing the fine radial pore-canals; *d*, nucleolar fibres (chromatin substance) of the nucleus. 2, 3. *Collozoum inermis*, J. Müller, two different forms of colonies, of the natural size. 4. Central capsule from a colony of *Collozoum inermis*, showing the intracapsular protoplasm and nucleus, broken up into a number of spores, the germs of swarm-spores or flagellulae;

each encloses a crystalline rod. *e*, yellow cells lying in the extracapsular protoplasm. 5. A small colony of *Collozoum inermis*, magnified 25 diameters. *a*, alveoli (vacuoles) of the extracapsular protoplasm; *b*, central capsules, each containing besides protoplasm a large oil-globule. 6-13. Yellow cells of various Radiolaria: 6, normal yellow cell; 7, 8, division with formation of transverse septum; 9, a modified condition according to Brandt; 10, division of a yellow cell into four; 11, amoeboid condition of a yellow cell from the body of a dead *Sphærozoum*; 12, a similar cell in process of division; 13, a yellow cell the protoplasm of which is creeping out of its cellulose envelope. 14. *Heliosphæra inermis*, Haeck., living example;  $\times 400$ . *a*, nucleus; *b*, central capsule; *c*, siliceous basket-work skeleton. 15. Two swarm-spores (flagellulae) of *Collozoum inermis*, set free from such a central capsule as that drawn in 4; each contains a crystal *b* and a nucleus *a*. 16. Two swarm-spores of *Collozoum inermis*, of the second kind, viz., devoid of crystals, and of two sizes, a macrospore and a microspore. They have been set free from central capsules with contents of a different appearance from that drawn in 4. *a*, nucleus. 17. *Actinomma asteracanthum*, Haeck.;  $\times 260$ ; one of the Peripylæa. Entire animal in optical section. *a*, nucleus; *b*, wall of the central capsule; *c*, innermost siliceous shell enclosed in the nucleus; *d*, middle shell lying within the central capsule; *e*, outer shell lying in the extracapsular protoplasm. Four radial siliceous spines, holding the three spherical shells together are seen. The radial fibrillation of the protoplasm and the fine extracapsular pseudopodia are to be noted. 18. *Amphilonche messanensis*, Haeck.;  $\times 200$ ; one of the Acanthometridæ. Entire animal as seen living.

## ORDER 2. MONOPYLÆA, Hertwig.

*Characters*.—Silico-skeletal Radiolaria in which the central capsule is not spherical but monaxonic (cone-shaped), with a single perforate area (pore-plate) placed on the basal face of the cone; the membrane of the capsule is simple, the nucleus single; the skeleton is extracapsular, and forms a scaffold-like or bee-hive-like structure of monaxonic form.

FIG. XV.—*Eucyrtidium cranioides*, Haeck.;  $\times 150$ ; one of the Monopylæa. Entire animal as seen in the living condition. The central capsule is hidden by the bee-hive-shaped siliceous shell within which it is lodged.

Fam. 1. PLECTIDA, Haeck. Skeleton formed of siliceous spines loosely conjoined.

Genera (selected).—*Plagiocantha*, Haeck.; *Plegmatium*, Haeck.

Fam. 2. CYRTIDA, Haeck. Skeleton a monaxonic or triradiate shell, or continuous piece (bee-hive-shaped).

Genera (selected).—*Halicalyptra*, Haeck.; *Eucyrtidium*, Haeck. (Fig. XV.); *Carpocantum*, Haeck. (Fig. XVI. 3).

Fam. 3. BOTRIDIA, Haeck. Irregular forms; the shell composed of several chambers agglomerated without definite order; a single central capsule.

Genera.—*Botryocyrtis*, Haeck.; *Lithobotrys*, Haeck.

Fam. 4. SPERIDA, Haeck. Gemminato forms, with shell consisting of two conjoined chambers; a single central capsule.

Fam. 5. STEPHIDA, Haeck. Skeleton ericoid, forming a single siliceous ring or several conjoined rings.

Genera (selected).—*Acanthodesmia*, Haeck.; *Zygostephanus*, Haeck.; *Lithocircus*, Haeck. (Fig. XVI. 1).

## ORDER 3. PHÆODARIA, Haeck. (Tripylæa, Hertwig).

*Characters*.—Silico-skeletal Radiolaria in which the central

which are totally devoid of skeleton. Similarly it does not appear to be a matter of great significance that some forms (Polycyttaria) form colonies, instead of the central capsules separating from one another after fission has occurred.

It is important to note that the skeleton of silox or acanthin does not correspond to the shell of other Gymnomyxa, which appears rather to be represented by the membranous central capsule. The skeleton does, however, appear to correspond to the spicules of Heliozoa, and there is an undeniable affinity between such a form as Clathrulina (Fig. VII. 2) and the Spherid Peripylea (such as Heliosphaera, Fig. XIV. 14). The Radiolaria are, however, a very strongly marked group, definitely separated from all other Gymnomyxa by the membranous central capsule sunk in their protoplasm. Their differences *inter se* do not affect their essential structure. The variations in the chemical composition of the skeleton and in the perforation of the capsule do not appear superficially. The most obvious features in which they differ from one another relate to the form and complexity of the skeleton, a part of the organism so little characteristic of the group that it may be wanting altogether. It is not known how far the form-species and form-genera which have been distinguished in such profusion by Haeckel as the result of a study of the skeletons are permanent (*i.e.*, relatively permanent) physiological species. There is no doubt that very many are local and conditional varieties of a single Protean species. The same remark applies to the species discriminated among the shell-bearing Reticularia. It must not be supposed, however, that less importance is to be attached to the distinguishing and recording of such forms because we are not able to assert that they are permanent species.

The yellow cells (of spherical form, .005 to 0.15 of a millimetre in diameter) which occur very generally scattered in the extracapsular protoplasm of Radiolaria were at one time regarded as essential components of the Radiolarian body. Their parasitic nature is now rendered probable by the observations of Cienkowski (43), Brandt (44), and Geddes (45), who have established that each cell has a cellulose wall and a nucleus (Fig. XIV. 6 to 13), that the protoplasm is impregnated by chlorophyll which, as in Diatoms, is obscured by the yellow pigment, and that a starch-like substance is present (giving the violet reaction with iodine). Further, Cienkowski showed, not only that the yellow cells multiply by fission during the life of the Radiolarian, but that when isolated they continue to live; the cellulose envelope becomes softened; the protoplasm exhibits amoeboid movements and escapes from the envelope altogether (Fig. XIV. 13) and multiplies by fission. Brandt has given the name *Zooxanthella nutricula* to the parasitic unicellular Alga thus indicated. He and Geddes have shown that a similar organism infests the endoderm cells of Anthozoa and of some Siphonophora in enormous quantities, and the former has been led, it seems erroneously, to regard the chlorophyll corpuscles of *Hydra viridis*, Spongilla, and Ciliata as also parasitic Algae, for which he has coined the name *Zoochlorella*. The same arguments which Brandt has used to justify this view as to animal chlorophyll would warrant the creation of a genus "*Phytochlorella*" for the hypothetical Alga which has hitherto been described as the "chlorophyll corpuscles" of the cells of ordinary green plants.

*Zooxanthella nutricula* does not, for some unknown reason, infest the Acanthometridae, and it is by no means so universally present in the bodies of the Silico-skeleta as was supposed before its parasitic nature was recognized.

The streaming of the granules of the protoplasm has been observed in the pseudopodia of Radiolaria as in those of Heliozoa and Reticularia; it has also been seen in the deeper protoplasm; and granules have been definitely seen to pass through the pores of the central capsule from the intracapsular to the extracapsular protoplasm. A feeble vibrating movement of the pseudopodia has been occasionally noticed.

The production of swarm-spores has been observed only in Acanthometra and in the Polycyttaria and Thalassicolidae, and only in the two latter groups have any detailed observations been made. Two distinct processes of swarm-spore production have been observed by Cienkowski (43), confirmed by Hertwig (46)—distinguished by the character of the resulting spores which are called "crystalligerous" (Fig. XIV. 15) in the one case, and "dimorphous" in the other (Fig. XIV. 16). In both processes the nucleated protoplasm within the central capsule breaks up by a more or less regular cell-division into small pieces, the details of the process differing a little in the two cases. In those individuals which produce crystalligerous swarm-spores, each spore encloses a small crystal (Fig. XIV. 15). On the other hand, in those individuals which produce dimorphous swarm-spores, the contents of the capsule (which in both instances are set free by its natural rupture) are seen to consist of individuals of two sizes "macrospores" and "microspores," neither of which contain crystals (Fig. XIV. 16). The further development of the spores has not been observed in either case. Both processes have been observed in the same species, and it is suggested that there is an alternation of sexual and asexual generations, the crystalligerous spores

developing directly into adults, which in their turn produce in their central capsules dimorphous swarm-spores (macrospores and microspores), which in a manner analogous to that observed in the Volvocinean Flagellata copulate (permanently fuse) with one another (the larger with the smaller) before proceeding to develop. The adults resulting from this process would, it is suggested, produce in their turn crystalligerous swarm-spores. Unfortunately we have no observations to support this hypothetical scheme of a life-history.

*Fusion or conjugation* of adult Radiolaria, whether preliminary to swarm-spore-production or independently of it, has not been observed—this affording a distinction between them and Heliozoa, and an agreement, though of a negative character, with the Reticularia.

*Simple fission* of the central capsule of adult individuals and subsequently of the whole protoplasmic mass has been observed in several instances, and is probably a general method of reproduction in the group.

The siliceous shells of the Radiolaria are found abundantly in certain rocks. They furnish, together with Diatoms and Spongespicules, the silica which has been segregated as flint in the Chalk formation. They are present in quantity (as much as 10 per cent.) in the Atlantic ooze, and in the celebrated "Barbados earth" (a Tertiary deposit) are the chief components.

#### GRADE B. *CORTICATA*, Lankester, 1878 (64).

*Characters.*—Protozoa in which the protoplasm of the cell-body, in its adult condition, is permanently differentiated into two layers, an outer denser cortical substance and an inner more fluid medullary substance (not to be confused with the merely temporary distinction of exoplasm and endoplasm sometimes noted in Gymnomyxa, which is not structural but due to the gravitation and self-attraction of the coarser granules often embedded in the uniformly fluid protoplasm).

Since the Corticata have developed from simple Gymnomyxa exhibiting both amoeboid and flagellate phases of form and activity, it results (1) that the forms of the body of many Corticata are traceable to modifications of these primitive forms; (2) that the young stages of the Corticata are in the lower classes of that group typical flagellulae or amoebulae; and (3) that there are certain archaic forms included in those lower classes whose position there is doubtful, and which might be with almost equal propriety assigned to the Gymnomyxa, since they are transitional from that lower grade to the higher grade of Corticata.

#### CLASS I. *SPOROZOA*, Leuckart (47); Syn. *Gregarinida*, Auct.

*Characters.*—Corticata parasitic in almost all classes and orders of animals, imbibing nutriment from the diffusible albuminoids of their hosts and therefore mouthless. In typical cases there is hatched from a chlamydospore one or more modified nucleate or non-nucleate flagellulae (falciform young, drepanidium phase). The flagellula increases in size and differentiates cortical and medullary substance. Fission is common in the younger stages of growth. The movements now become neither vibratile nor amoeboid but definitely restrained, and are best described as "euglenoid" (*cf.* Flagellata, Fig. XX. 27, 28). The nucleus is single, large, and spherical. No contractile vacuole and rarely any vacuole is present. A size of  $\frac{1}{16}$ th inch may be attained in this phase, which may be definitely spoken of as the euglena phase corresponding to the amoeba phase of Gymnomyxa. It is usually of oblong form, with sac-like contractile wall of cortical substance, but may be spherical (Coccidiiden) or even amoeboid (Myxosporidia).

Conjugation, followed directly or after an interval by sporulation, may now ensue. The conjugated individuals (two), or sometimes a single individual, become encysted. The contents of the cysts now rapidly divide (by a process the details of which are unknown) into minute ovoid nucleated (?) bodies; sometimes a portion of the protoplasm is not converted into spores but may form sporoducts (*cf.* capillitium of Mycetozoa). Each piece acquires a special chitin-like colourless coat, and is then a chlamydospore. Rarely one spore only is formed from the whole contents of a cyst. The spore-coat is usually thick, and remarkable for processes and other accessory developments. The included protoplasm of the chlamydospore frequently divides into several pieces before hatching. These usually, when set free from the spore-coat, have the form of modified nucleated flagellulae, *i.e.*, flagellulae in which the protoplasm is not drawn out into a thread-like flagellum but exhibits an elongate form, uniformly endowed with vibratile activity. With few (if any) exceptions, the falciform young thus characterized penetrates a cell of some tissue of its host and there undergoes the first stages of its growth (hence called Cytosoa). In some forms the pre-cystic phase never escapes from its cell host. In other cases it remains connected with the hospitable cell long after it has by growth exceeded by many hundred times the bulk of its quondam entertainer; often it loses all connexion with its cell host and is carried away to some other part of the infested animal before completing its growth and encysting.

The Sporozoa are divided into four sub-classes, differing from one another according to the form and development attained by the euglena phase. We shall place the most highly developed first, not only because our knowledge about it is most complete, but because it is possible that one at least of the other sub-classes is derived by degeneration from it.

#### SUB-CLASS I. Gregarinidea, Bütschli (9).

**Characters.**—Sporozoa in which the euglena phase is dominant, being relatively of large size, elongate in form, definitely shaped, having contractile but not viscid cortex, and exhibiting often active nutritional and locomotor phenomena. Though usually if not invariably cell-parasites in early youth, they become free before attaining adult growth, and inhabit either the body-cavity or the intestine of their hosts. Many spores are produced in the encysted phase. The spores have an oblong, sometimes caudate coat, and produce each one or several falciform young. At present only known as parasites of Invertebrata.

FIG. XVII.—Sporozoa. 1, 2. *Monocystis agilis*, Stein; x250; from the testis of the Earthworm. Two phases of movement—a ring-like contraction passing along the body from one end to the other. 3. Individual of the same species which has penetrated in the young stage a sperm-cell of the Earthworm, and is now clothed as it were with spermatoblasts. 4. *Monocystis magna*, A. Schmidt, from the testis of the Earthworm (*L. terrestris*, L.). 5. Tailed chlamydospore of *Monocystis saxuridis*, Koll. 6. Two *M. agilis* encysted, spores forming on the surface of the protoplasm. 7. A similar cyst further advanced in spore-formation (see Fig. XVIII.). 8. Spore of *M. agilis*, nucleus. x 1400. 9. The shaped coat. a, nucleus. 10. Into several falciform swarm-spores unused. b, Schneider's residual core. 11. Optical transverse section of a completed spore. b, Schneider's residual core. 12. Chlamydospore of *Klossia chitonis*, nov. sp., from the liver of Chiton (original). 13, 14. Chlamydospore of *Monocystis saxuridis*, Koll. (from its fibrillation after Lankester, 54). 15. A single falciform young. 16. A single falciform young. 17. A single falciform young. 18. A single falciform young. 19. A single falciform young. 20. A single falciform young. 21. A single falciform young. 22. A single falciform young. 23. A single falciform young. 24. A single falciform young. 25. A single falciform young. 26. A single falciform young. 27. A single falciform young. 28. A single falciform young. 29. A single falciform young. 30. A single falciform young. 31. A single falciform young. 32. A single falciform young. 33. A single falciform young. 34. A single falciform young. 35. A single falciform young. 36. A single falciform young. 37. A single falciform young. 38. A single falciform young. 39. A single falciform young. 40. A single falciform young. 41. A single falciform young. 42. A single falciform young. 43. A single falciform young. 44. A single falciform young. 45. A single falciform young. 46. A single falciform young. 47. A single falciform young. 48. A single falciform young. 49. A single falciform young. 50. A single falciform young. 51. A single falciform young.

17. *Monocystis agilis*, Stein, Fig. XVII. 1, 2, 3, 6, 7, 8, 9, 10, 11, and Fig. XVIII. is the type. The other species of *Monocystis* occur chiefly (and very commonly) in marine Annelids, Platyhelminthes, Gephyrea, and Tunicata; not in Arthropoda, Mollusca, nor Vertebrata. The only definite differences which they present of possibly more than specific worth, as compared with *M. agilis*, are in the form of the chlamydospores, which are sometimes tailed, as in *M. saxuridis* (Fig. XVII. 5), and in *M. nemertis* (Fig. XVII. 19) and *M. sipunculi*, and further also certain differences in the general form, as for instance the anchor-like *M. sagittata* (Fig. XVII. 23), and the probosciferous *M. aphrodites* (Fig. XVII. 17). The fine parallel striation of the cuticle in some species (*M. scirpula*, &c.) might also be made the basis of a generic or sub-generic group.

On the whole it seems best to leave all the species for the present in the one genus *Monocystis*, pending further knowledge. It seems probable that more than one species (at least two, *M. agilis* and *M. magna*) infest the common Earthworm.

#### ORDER 1. HAPLOCYTA, Lankester.

**Characters.**—Gregarinidea in which there is never at any time a partition of the medullary substance into two or more chambers. The euglenoid is always a single contractile sac with one mass of medullary substance in which floats the large vesicular transparent nucleus. Spores larger than in the next group, each producing several falciform young.

Genus unicum.—*Monocystis*, Stein, 1848. The various generic subdivisions proposed by Aim. Schneider (48), and accepted by Bütschli, appear to the present writer to have insufficient characters, and serve to complicate rather than to organize our knowledge of the subject. We do not yet know enough of the sporulation and subsequent development of the various monocystic Gregarinides to justify the erection of distinct genera.

*Monocystis agilis*, Stein, Fig. XVII. 1, 2, 3, 6, 7, 8, 9, 10, 11, and Fig. XVIII. is the type. The other species of *Monocystis* occur chiefly (and very commonly) in marine Annelids, Platyhelminthes, Gephyrea, and Tunicata; not in Arthropoda, Mollusca, nor Vertebrata. The only definite differences which they present of possibly more than specific worth, as compared with *M. agilis*, are in the form of the chlamydospores, which are sometimes tailed, as in *M. saxuridis* (Fig. XVII. 5), and in *M. nemertis* (Fig. XVII. 19) and *M. sipunculi*, and further also certain differences in the general form, as for instance the anchor-like *M. sagittata* (Fig. XVII. 23), and the probosciferous *M. aphrodites* (Fig. XVII. 17). The fine parallel striation of the cuticle in some species (*M. scirpula*, &c.) might also be made the basis of a generic or sub-generic group.

On the whole it seems best to leave all the species for the present in the one genus *Monocystis*, pending further knowledge. It seems probable that more than one species (at least two, *M. agilis* and *M. magna*) infest the common Earthworm.

#### ORDER 2. SEPTATA, Lankester.

**Characters.**—Gregarinidea in which in the adult the medullary substance is separated into two chambers—a smaller anterior (the

protomerite) and a larger posterior (the dermal) nucleus. There is frequently if not always an early growth or more persistently, an anterior protomerite growing from the protomerite, which serves to attach the parasite to its host, and which it is always shed sooner or later. The phase in which it is present is called a "cephalopod" (see Fig. XIX, 2). The spores are broken off a "sporont" (see Fig. XIX, 2). The spores are smaller than in the preceding group, often very small (Fig. XIX, 2). The spores are sometimes only a single (?) salemform, sometimes a pair of different

only a single (?) salemform *Sp.* at different Dufour; *Hoplophrynos*, *H.* by Aimé {The numerous genera which have been proposed times by Hammerschmidt and others, and more recently Schneider, appear to the present writer to be unserviceable. The to the fact that our knowledge is as yet very incomplete. good basis for generic or family distinctions might probably be found in the greater or less elaboration of the cyst and the formation or not of sporoducts. But of the majority of Septata we do not know the cysts or the history of sporulation; we merely know that some have simple cysts with complete sporulation leaving no residue of protoplasm, and that others form cysts with double walls and elaborate tubular ducts, whilst a part of the protoplasm is not sporulated but forms a capillitium (Fig. XIX. 2).

Another possible basis for generic division of the Septata may be found in the characters of the epimerite. This may be present or absent altogether. It may exist only in the young condition or persist until growth is completed. It may be simple, short, elongate, or provided with hooklets. The presence of hooklets on the epimerite is the only character which at present seems to serve conveniently for generic distinction. With regard to the other points mentioned we are not sufficiently informed, since we know the complete history of development from the young form set free from the spore in only one or two cases.]

The Septata are found exclusively in the alimentary canals of Arthropoda (Insects, Myriapods, Crustacea, not Arachnida). See Fig. XIX. for various examples of the group.

FIG. XVIII.—Cyst of *Sponcoyatis agilis*, the coramon Gregarinid of the Earthworm;  $\times 150$  diam.; showing ripe ellamydospores and complete absence of any residual protoplasm or other material in the cyst (original).

SUB-CLASS II. Coccidiidea, Bütschli (9).

Sporozoa in which the euglena phase remains of relatively minute size, of spherical shape and simple egg-cell-like structure. It is not locomotive, but continues, until the cyst is formed, to inhabit a single cell of the host. Many, few, or one single chimney-shaped are formed in the cyst. One or more falciform young escape from each spore, and exhibit active movements (flagellula-like) leading to a penetration of a tissue-cell by the young form as in Gregarinidea. Many are parasites of Vertebrata.

ORDER 1. MONOSPOREA, Aim. Schn.

*Characters.*—The whole content of the cyst forms but a single spore.

Genus unicum.—*Eimeria* (in the intestinal epithelium of Triton, Frog, Sparrow, Mouse, and the Myriapods *Lithobius* and *Glomeris*, Fig. XVII. 35 to 39).

Fig. XLX.—Sporozoa (Septista). 1. *Gregarina blattarum*, Siebold, 2.  
the intestine of *Blatta orientalis*;  $\times 80$ . A syzgium of two individuals, 3.  
Each animal consists of a small anterior chamber, the protomerite, 4.  
large posterior chamber, the deutomerite, in which is the nucleus, 5.  
Over-ripe cyst of *Gregarina blattarum*, with thick gelatinous envelope, 6.  
and projecting sporoducts *d*. The spores have been nearly all dis- 7.  
solved. Around the central mass of spores is rendered visible the 8.  
work of protoplasmic origin in which the ejected spores were emb- 9.  
bedded. This distinctly resembles in origin and function the capillitium 10.  
of Mycetozoa (Fig. III.). *a*, the plasmatic channels leading to the everted 11.  
sporoducts; *b*, the still remaining spores; *c*, the proper cyst-wall; and 12.  
everted sporoducts; *e*, the gelatinous envelope. 3. A ripe s- 13.  
pore of *Gregarina blattarum*, a long time after its e- 14.  
jection from the cyst;  $\times 1600$  diam. 4. Commencing encystment of a s- 15.  
pore of *G. blattarum*. *a*, protomerite of one individual; *b*, gelatin- 16.  
ous envelope; *c*, promerite of the second individual. 5. Three epithe- 17.  
lial cells of the mid-gut of *Blatta orientalis*, into the end of each of which 18.  
an extremely young *Gregarina blattarum* has made its way. 6. Part 19.  
of the substance of the young *Gregarina*; only the epimerite *a* is now bur- 20.  
ied in the epithelial cell, and this will soon break off and set 21.  
free the *Gregarina*. It is now a "cephalont"; it will then become a "spor- 22.  
ont". 7. Usual part of an everted sporoduct of *Gregarina blattarum*. *a*, gra- 23.  
nular fibrous mass investing the base of the duct; *b*, commencement of 24.  
an invaginated cuticular formation before its eversion. 8. *Gregar-* 25.  
 *gigantea*, L. Van Ben., from the intestine of the Lobster;  $\times 150$ . *a*, nuclei

9. Anterior end of the same more highly magnified. *a*, protomerite; *b*, layer of circular fibrillæ lying below the cuticle; *c*, cortical substance of the deutomerite; *d*, medullary substance of the deutomerite. 10. Two spores of *Gregarina gigantea* (after Bütschli), showing the very thick coat of the spore. 11-15. Stages in the development of *Gregarina gigantea*:—11, recently escaped from the spore-coat, no nucleus; 12, still no nucleus, one vibratile and one motionless process; 13, the two processes have divided; one here drawn has developed a nucleus; 14, further growth; 15, the deutomerite commences to develop. 16. Cysts of *Gregarina gigantea*, from the rectum of the Lobster. The double contents are believed by Ed. Van Beneden to be due not to conjugation previous to encystment but to subsequent fission. 17, 18. *Gregarina longicollis*, Stein, from the intestine of *Blaps mortisieri*:—17, cephalont phase, with a long proboscis-like epimerite *a*, attached to the protomerite *b*; 18, sporont phase, the epimerite having been cast preliminarily to syzygy and encystment. 19. *Gregarina Manteri*, Aim. Schneider, from the intestine of *Timarcha tenebricosa*, to show the network of anastomosing fibres beneath the cuticle, similar to the annular fibrillæ of *G. gigantea* shown in 9. 20. *Gregarina (Hyporhynchus) oligacanthus*, Stein, from the intestine of the larva of Agrion. Cephalont with spine-crowned epimerite *a*. 21. Spores of *Gregarina oligacanthus*. 22, 23. *Gregarina (Hyporhynchus) Dujardini*, Aim. Schneider, from the intestine of *Lithobius forficatus*:—22, specimen with epimerite *a*, therefore a "cephalont"; 23, specimen losing its epimerite by rupture and becoming a "sporont."

#### ORDER 2. OLIGOSPOREA, Aim. Schn.

**Characters.**—The cyst-content develops itself into a definite and constant but small number of spores.

Genus unicum.—*Coccidium*, Leuck. (in intestinal epithelium and liver of Mammals, and some Invertebrates, Figs. XVII. 24 to 31).

#### ORDER 3. POLYSPOREA.

**Characters.**—The cyst-content develops itself into a great number of spores (sixty or more).

Genus unicum.—*Klossia*, Aim. Schn. Three species of *Klossia* are found in Mollusca—viz., in *Helix*, in Cephalopods, and in Chiton. Schneider's genus, *Adelea*, from *Lithobius*, appears to belong here. Kloss (49) discovered the parasite of the renal cells of *Helix hortensis* represented in Fig. XVII. 18, 19, 20, 21, and 22; Schneider that of Cephalopods, Fig. XVII. 32, 33. In Chiton Dr Tovey has discovered a third species with very remarkable spores, which are here figured for the first time (Fig. XVII. 12).

The *Drepanidium Barnum* (Fig. XVII. 45, 46, 47), discovered by Lankester (50) in the Frog's blood, is probably the falciform young of a *Coccidium* parasitic in the Frog's kidney, and discovered there by Lieberkühn (51). A spore of this *Coccidium* is shown in Fig. XVII. 48; whilst in 46 two *Drepanidia* which have penetrated a red-blood corpuscle of the Frog are represented.

The Polysporous *Coccidiidea* come very close to the Gregarinidea genus *Monocystis*, from which they may be considered as being derived by an arrest of development. The spores and falciform young of the *Coccidiidea* are closely similar to those of *Monocystis*, and the young in both cases penetrate the tissue-cells of their host; but in *Monocystis* this is only a temporary condition, and growth leads to the cessation of such "cell-parasitism." On the other hand, growth is arrested in the *Coccidiidea*, and the organism is permanently a cell-parasite.

Since the parasitism is more developed in the case of a cell-parasite than in the case of a parasite which wanders in the body cavity, it seems probable that the *Coccidiidea* have been derived from the Gregarinidea rather than that the reverse process has taken place.

#### Sub-class III. Myxosporidia, Bütschli.

**Characters.**—Sporozoa in which the euglena-phase is a large multinucleate amoeba-like organism (Fig. XVII. 34). The cysts are imperfectly known, but appear to be simple; some attain a diameter of two lines. The spores are highly characteristic, having each a thick coat which is usually provided with a bifurcate process or may have thread capsules (like nematocysts) in its substance (Fig. XVII. 40, 41, 42, 43, 44).

The spores contain a single nucleus, and are not known to produce falciform young, but in one case have been seen to liberate an amoeba. The further development is unknown. The Myxosporidia are parasitic beneath the epidermis of the gills and fins, and in the gall-bladder and urinary bladder of Fishes, both freshwater and marine.

Genera.—*Myxidium*, Bütschli (Pike, Fig. XVII. 34); *Myxobolus*, Bütschli (Cyprinoids); *Lithocystis*, Giard (the Lamellibranch *Echinocardium*).

The Myxosporidia are very imperfectly known. They present very close affinities to the Mycetozoa, and are to be regarded as a connecting link between the lower Gymnomyxa and the typical Sporozoa. Possibly their large multinucleate amoeba phase is a plasmodium formed by fusion of amoebæ set free from spores, though it is possible that the many nuclei are the result of a division of an original single nucleus, preparatory to sporulation.

Their spores are more elaborate in structure than those of any other Protozoa, and are more nearly paralleled by those of some species of *Monocystis* than by those of *Mycetozoa*. The thread-capsules of the spores are identical in structure with those of *Hydrozoa*, and probably serve as organs of attachment, as do the furcate processes of the spore-case. It is not certain that a definite

cyst is always or ever formed, but as occurs rarely in some Gregarinidea, the spores may be formed in a non encysted amoeba form.

Although pseudopodia, sometimes short and thread-like, have been observed in the amoeba phase, yet it is also stated that a distinction of cortical and medullary substance obtains.

The "psorosperms" of J. Müller are the spores of Myxosporidia.

#### Sub-class IV. Sarcocystidia, Bütschli.

(This division is formed by Bütschli for the reception of Sarcocystis, parasitic in the muscular fibres of Mammals, and of *Amœbidium*, parasitic in Crustacea. Both are very insufficiently known, but have the form of tubular protoplasmic bodies in which numerous ovoid spores are formed from which falciform young escape.)

Genera.—*Sarcocystis*, Lankester; *Amœbidium*, Cienkowski (52). *Sarcocystis* (Fig. XVII. 50, 51, *S. Miescheri*, Lank.), was first observed by Miescher in the striated muscle-fibres of the Mouse; then by Rainey in a similar position in the Pig, and taken by him for the youngest stage in the development of the cysts of *Tænia solium*; subsequently studied by Beale and others in connexion with the cattle-plague epidemic, and erroneously supposed to have a causal connexion with that disease. It is common in healthy butcher's meat. See Lanekart (47).

**Further remarks on the Sporozoa.**—The Sporozoa contrast strongly with the large classes of Gymnomyxa, the Heliozoa, Reticularia, and Radiolaria, as also with the Ciliate and Tentaculiferous Corticata, by their abundant and rapidly recurrent formation of spores, and agree in this respect with some *Proteomyxa*, with *Mycetozoa*, and some *Flagellata*. Their spores are remarkable for the firm, chitin-like spore-coat and its varied shapes, contrasting with the cellulose spherical spore-coat of *Mycetozoa* and with the naked spores of *Radiolaria* and *Flagellata*.

The protoplasm of the more highly developed forms (Gregarinidea) in the englenoid phase exhibits considerable differentiation. Externally a distinct cuticle may be present, marked by parallel rugæ (*Monocystis serpulae*) or by fine tubercles (*Monocystis sipunculii*). A circlet of hooks may be formed by the cuticle at one end of the body. Below the cuticle is sometimes developed a layer of fibrils running transversely to the long axis of the body (Fig. XIX. 9 and 19), which have been regarded as contractile, but are probably cuticular. The cortical layer of protoplasm below these cuticular structures is dense and refringent and sometimes fibrillated (*Monocystis pellucida*, Fig. XVII. 15). It is the contractile substance of the organism, and encloses the finely granular more liquid medullary substance. The granules of the latter have been shown by Bütschli (9) to give a starch-like reaction with iodine, &c. Probably the protoplasm in which they lie is finely reticulate or vacuolar, and when the granules are few it is actually seen to be so. No contractile vacuole is ever present. In Myxosporidia the medullary protoplasm is coloured yellow by hematoïdin derived from the blood of its host or by absorbed bile-pigment, and also contains small crystals.

The nucleus of the Gregarinidea is a large clear capsule, with a few or no nucleolar granules. It has never been seen in a state of division, and it is not known what becomes of it during sporulation, though sporulating Gregarinidea have been observed with many minute nuclei scattered in their protoplasm, presumably formed by a breaking up of the single nucleus.

The habit of attaching themselves in pairs which is common in Gregarinidea is perhaps a reminiscence of a more extensive formation of aggregation plasmodia (compare *Mycetozoa*). The term "syzygium" is applied to such a conjunction of two Gregarinidea; it is not accompanied by fusion of substance. The formation of cysts is not connected with this pairing, since the latter occurs in young individuals long before encystment. Also cysts are formed by single Gregarinidea, as is always the case in the non-motile *Coccidiidea*.

The encystment always leads to the formation of spores, but in rare cases sporulation has been observed in unencysted Gregarinidea, and it occurs perhaps normally without true cyst-formation in the Myxosporidia.

The cell-parasitism of the young Sporozoa, and their flagellula-like (falciform) young and active vibratile movement, are points indicating affinity with the lower Gymnomyxa, and especially with those *Proteomyxa*, such as *Vampyrella* and *Plasmodiophora*, which are cell-parasites. Indeed it is probable that we have in this fact of cell-parasitism, and especially of parasitism in animal cells, a basis for the theoretical association of several unicellular organisms. The Haplococcus of Zopf (regarded by him as a *Mycetozoon*) is parasitic in the muscular cells of the Pig, and is probably related to *Sarcocystis*. Recently Von Lendenfeld (53) has described in Australia an amoeba-like organism as parasitic in the skin of Sheep, which will probably be found to be either a Sporozoon or referable to those parasitic spore-producing *Proteomyxa* which are separated from Sporozoa only by their negative characters (see previous remarks on the negative characters of *Proteomyxa*).

The application of the name "Gregarines" has sometimes been

made erroneously to external parasitic organisms, which have nothing in common with the Sporozoa. This was the case in regard to a fungoid growth in human hair—the so-called "chignon Gregarine." The Silk-worm disease known as "pebrine" has also been attributed to a Gregarine. It seems probable that the parasitic organism which causes that disease is (as is also the distinct parasite causing the disease known as "flaccidez" in the same animals) one of the Schizomycetes (Bacteria). No disease is known at present as due to Sporozoa, although (e.g., the *Klossia chitonis*) they may lead to atrophy of the organs of the animals which they infest, in consequence of their enormous numbers. Coccidia and Sarcocysts are stated to occur in Man.

## CLASS II. FLAGELLATA,<sup>1</sup> Ehrenberg.

**Characters.**—Corticata in which the dominant phase in the life-history is a corticate flagellula, that is, a nucleated cell-body provided with one or a few large processes of vibratile protoplasm. Very commonly solid food particles are ingested through a distinct cell-mouth or aperture in the cortical protoplasm, though in some an imbibition of nutritive matter by the whole surface and a nutritional process chemically resembling that of plants (holophytic), chlorophyll being present, seems to occur.

Conjugation followed by a breaking up into very numerous minute naked spores is frequent in some; as also a division into small individuals (microgonidia), which is followed by their conjugation with one another or with big individuals (macrogonidia) and subsequent normal growth and binary fission.

Many have a well-developed cuticle, which may form collar-like outgrowths or stalk-like processes. Many produce either gelatinous or chitin-like shells (cups or cencæia), which are connected so as to form spherical or arborescent colonies; in these colonies the protoplasmic organisms themselves produce new individuals by fission, which separate entirely from one another but are held together by the continuity, with those already existing, of the new shells or jelly-houses or stalk-like supports produced by the new individuals. A single well-marked spherical nucleus, and one or more contractile vacuoles, are always present in the full-grown form.

Often, besides ingested food-particles, the protoplasm contains starch granules (amylon nucleus), paramylum corpuscles, chromatophores and chlorophyll corpuscles, some of which may be so abundant as to obscure the nucleus. One or two pigment spots (stigmata or so-called eye-spots) are often present at the anterior end of the body.

### SUB-CLASS I. Lissoflagellata, Lankester.

Never provided with a collar-like outgrowth around the oral pole.

#### ORDER 1. MONADIDEA, Bütschli.

**Characters.**—Lissoflagellata of small or very small size and simple structure; often naked and more or less amœboid, sometimes forming tests. Usually colourless, seldom with chromatophores. With a single anterior large flagellum or sometimes with two additional paraflagella. A special mouth-area is often wanting, sometimes is present, but is never produced into a well-developed pharynx.

**Fam. 1. RHIZOMASTIGINA, Bütschli.** Simple mouthless forms with 1 to 2 flagella; either permanently exhibiting a Gymnomyxa-like development of pseudopodia or capable of passing suddenly from a firm-walled into a Gymnomyxa-like condition, when the flagella may remain or be drawn in. Ingestion of food by aid of the pseudopodia.

**Genera.**—*Mastigamœba*, F. E. Schultze; *Ciliophrys*, Cienkowski (65); *Dimorpha*, Gruber; *Actinomonas*, Kent; *Trypanosoma*, Gruby (parasitic in the blood of Frogs and other Amphibia and Reptiles, Fig. XX. 21, 22). The Rhizomastigina might all be assigned to the Proteomyxa, with which they closely connect the group of Flagellata. The choice of the position to be assigned to such a form as *Ciliophrys* must be arbitrary.

**Fam. 2. CERCOMONADINA, Kent.** Minute oblong cell-body which posteriorly may exhibit amœboid changes. One large anterior flagellum. Mouth at the base of this organ. Reproduction by longitudinal fission and by multiple fission producing spores in the encysted resting state.

**Genera.**—*Cercomonas*, Duj. (Fig. XX. 32, 33); *Hercptomonas*, S. Kent; *Oikomonas*, Kent (= *Monas*, James Clark; *Pseudospora*, Cienkowski, Fig. XX. 29, 30, 31); *Ancyromonas*, S. K.

**Fam. 3. CODONOCINA, Kent.** Small colourless monads similar to *Oikomonas* in structure, which secrete a fixed gelatinous or membranous envelope or cup.

**Genera.**—*Codonacer*, James Clark; *Platytheca*, Stein.

**Fam. 4. BIKACINA, Stein.** Distinguished from the last family by the fact that the monad is fixed in its cup by a contractile thread-like stalk; cup usually raised on a delicate stalk.

**Genera.**—*Bicosaca*, J. Cl.; *Poteriodendron*, Stein.

<sup>1</sup> Bütschli's work (9) has been pretty closely followed in the diagnosis of the groups of Flagellata and the enumeration of genera here given.

FIG. XX.—Flagellata. 1. *Chlamydon* (From.); one of the Phytomastigoda; 2. Resting stage of the same, with fourfold division of the cell-contents. Letters as before. 3. Breaking up of the cell-contents into minute biflagellate swarm-spores, which escape, and whose history is not further known. 4. *Synerygia volvox*, Ehr.; one of the Phytomastigoda. 5. *Uroglena volvox*, Ehr.; one of the Phytomastigoda. 6. *Chlorogonium euchlorum*, Ehr.; one of the Phytomastigoda. 7. *Chlorogonium euchlorum*, Ehr.; one of the Phytomastigoda. 8. Colony of *Dinobryon sertularia*, Ehr.; one of the Monadidea. 9. *Hæmatococcus palustris*, Gird (= *Chlamydococcus*, Braun, *Protococcus* Cohn), one of the Phytomastigoda; ordinary individual with widely separated test. 10. Dividing resting stage of the same, with eight fission products in the common test. 11. A microgonidium of the same. 12. *Phalansterium consociatum*, Cienk.; one of the Choanoflagellata; × 325. Disk-like colony. 13. *Euglena viridis*, Ehr.; × 300; one of the Euglenoida. 14. *Gonium pectorale*, O. F. Muller; one of the Phytomastigoda. Colony seen from the flat side. × 300. 15. *Dinobryon sertularia*, Ehr.; one of the Monadidea. a, nucleus; b, con-

tractile vacuole; c, amylo-nucleus; d, free not belonging to Dinobryon; e, stigma.

16. *Peranema trichophorum*, Ehr., (one of individual seen from the back;  $\times 140$ ). a, nucleus; b, contractile vacuoles; c, pharynx; d, mouth.

17. Anterior end of *Euglena acus*, Ehr., in profile. a, mouth; b, contractile vacuoles; c, pharynx; d, stigma (eye-spot); e, paramylum-body; f, chlorophyll corpuscles.

18. Part of the surface of a colony of *Volvox globator*, L. (Phytomastigoda), showing the intercellular connective fibrils. a, nucleus; b, contractile vacuole; c, amylo-nucleus.

19. Two microgonidia of *Volvox globator*, L. a, nucleus; b, contractile vacuole.

20. Ripe asexually produced daughter-individual of *Volvox minor*, Stein, still enclosed in the cyst of the partheno-gonidium. a, young partheno-gonidia.

21, 22. *Trypanosoma sanguinis*, Gruby; one of the Rhizomastigina, from the blood of *Rana esculenta*. a, nucleus.  $\times 500$ .

23-26. Reproduction of *Bodo caudatus*, Duj. (one of the Heteromastigoda), after Dallinger and Drysdale:—23, fusion of several individuals (plasmodium); 24, encysted fusion-product; dividing into four; 25, later into eight; 26, cyst filled with swarm-spores.

27. *Ataria tenax*, O. F. Müller (Proteus); one of the Euglenoidea;  $\times 440$ . Individual with the two flagella, and strongly contracting hinder region of the body. a, nucleus; b, contractile vacuole, close to the pharynx.

28. The same devoid of flagella. a, nucleus; c, e, the two dark pigment spots (so-called eyes) near the mouth.

29. *Okomonas termo* (*Monas termo*) Ehr.; one of the Monadidea. a, nucleus; b, contractile vacuole; c, food-ingesting vacuole; d, food-particle.  $\times 440$ .

30. The food-particle d has now been ingested by the vacuole.

31. Adherent stalk. a, nucleus; d, vacuole.

32, 33. Cercoring two conditions of the b, contractile vacuoles; c, mouth.

Fam. 5. HETEROMONADINA, Bütschli. Small colourless or green monads which possess, besides one chief flagellum, one or two smaller paraflagella attached near it, often forming colonies secreting a common stalk.

Genera.—*Monas* (Ehr.), Stein; *Dendromonas*, Stein; *Cephalothamnium*, Stein; *Anthophysa*, Bory d. Vinc. (Fig. XXI. 12, 13); *Dinobryon*, Ehr. (Fig. XX. 8 and 15); *Epipyxis*, Ehr.; *Uroglena*, Ehr. (Fig. XX. 5).

## ORDER 2. EUGLENOIDEA, Bütschli.

**Characters.**—Generally somewhat large and highly developed monoflagellate forms, of monaxonic or slightly asymmetrical build. Cuticle present; cortical substance firm, contractile, and elastic; some forms quite stiff, others capable of definite annular contraction and worm-like elongation. At the base of the flagellum a small or large mouth leading into a more or less distinct pharyngeal tube. Near this is always the contractile vacuole. Rarely a pair of flagella instead of one.

Fam. 1. CÆLOMONADINA. Coloured Euglenoidea, with numerous small chlorophyll corpuscles or 1 to 2 large plate-like green or brown chromatophors. Mouth and pharynx inconspicuous; nutrition probably largely vegetal (holophytic).

Genera.—*Cælomonas*, Stein; *Gonyostomum*, Dies.; *Vacuolaria*, Cienk.; *Microglena*, Ehr.; *Chromulina*, Cienk.; *Cryptoglena*, Ehr.

Fam. 2. EUGLENA, Stein. Body monaxonic, elongated, hinder end pointed. Spirally striated cuticle. A fine mouth-aperture leads into the well-developed tubular pharynx. Flagellum usually single, sometimes paired, often cast off. Near the pharynx is the "reservoir" of the contractile vacuoles and several of the latter. A single (sometimes two) stigma or colour-speck near the same spot. Chromatophors nearly always present, generally bright green. A large nucleus in the middle of the body. Multiplication by longitudinal fission. Encysted condition and attendant fission imperfectly studied. Copulation doubtful.

Genera.—(a) With flexible cuticle:—*Euglena*, Ehr. (Fig. XX. 13, 17; this is probably Priestley's "green matter," from which he obtained oxygen gas; though one of the very commonest of all Protozoa, its life-history has yet to be worked out); *Colacium*, Ehr.; *Eutreptia*, Perty.

(b) With stiff, shell-like cuticle:—*Ascoglena*, Stein; *Trachelomonas*, Ehr.; *Lepocinclis*, Perty; *Phacus*, Nitzsch.

Fam. 3. MEXOIDINA, Bütschli. Similar to the Euglenina, but devoid of chlorophyll, a deficiency connected with the saprophytic mode of life. Stigma always absent.

Genera.—(a) With flexible cuticle:—*Astasiopsis*, Bütschli; *Astasiodes*, Bütschli.

(b) With stiff cuticle and non-contractile body:—*Monoidium*, Perty; *Atractonema*, Stein; *Rhabdomonas*, Fresenius.

Fam. 4. PERANEMINA. Very contractile (metabolic) colourless Euglenoids. Mouth and pharynx large; inception of solid nutrient certainly observed.

Genera.—*Peranema*, Duj. (Fig. XX. 16); *Urceolus*, Meresch.

Fam. 5. PETALOMONADINA. Colourless, non-metabolic forms. Mouth opening at the base of the single large flagellum.

Genera.—*Petalomonas*, Stein.

Fam. 6. ASTASINA. Colourless, metabolic, or stiff Euglenoids, differing from the rest in having a small or large paraflagellum in addition to the chief one. Nutrition partly saprophytic partly animal.

Genera.—*Astasia*, Ehr. emend. Stein (Fig. XX. 27, 28); *Heteronema*, Duj.; *Zygoselmis*, Duj.; *Sphenomonas*, Stein; *Tropidoscaphus*, Stein.

## ORDER 3. HETEROMASTIGODA, Bütschli.

**Characters.**—Small and large monads. Naked and even amoeboid or with stiff cuticle. Two flagella at the anterior end differing in size: the smaller directed forwards subserves the usual locomotor function; the larger is directed backwards and trailed, without movement. Sometimes two backwardly directed flagella are present. Always a mouth and animal nutrition. Always colourless.

Fam. 1. BODONINA, Bütschli. Size of the two flagella not very different.

Genera.—*Bodo*, Ehb. emend. Stein (Fig. XX. 23 to 26, and Fig. XXI. 10; the hooked monad and the springing monad of Dallinger and Drysdale (66); *Heteromita* of Dujardin (and Kent); *Phyllomitus*, Stein; *Colponema*, Stein; *Dallingeria*, Kent; *Trimastix*, Kent.

Fam. 2. ANISONEMINA, Kent. Large forms with cuticle; difference of the two flagella considerable. Mouth, pharynx, and animal nutrition.

Genera.—*Anisonema*, Duj.; *Entosiphon*, Stein.

## ORDER 4. ISOMASTIGODA, Bütschli.

**Characters.**—Small and middle-sized forms of monaxonic rarely bilateral shape. Fore-end with 2, 4, or seldom 5 equal-sized and similar flagella. Some are coloured, some colourless; naked or with strong cuticle or secreting an envelope. Mouth and pharynx seldom observed; nutrition generally holophytic (i.e., like a green plant), but in some cases, nevertheless, holozoic (i.e., like a typical animal).

Fam. 1. AMPHIMONADINA. Small, colourless, biflagellate Isomastigoda.

Genera.—*Amphimonas*, Duj. (1 *Pseudospora*, Cienk.).

Fam. 2. SPONGOMONADINA, Stein. Small colourless oval forms with two closely contiguous flagella. Chief character in the union of numerous individuals in a common jelly or in branched gelatinous tubes, the end of each of which is inhabited by a single and distinct individual.

Genera.—*Spongomonas*, Stein; *Cladomonas*, Stein; *Rhipidomonas*, Stein.

[Group Phytomastigoda, Bütschli. The following three families, viz., Chrysomonadina, Chlamydomonadina, and Volvocina, are so closely related to one another as to warrant their union as a sub-order. They are typical Isomastigoda, but have chlorophyll corpuscles and holophytic nutrition with correlated deficient mouth and pharynx. They are usually regarded by botanists as belonging to the unicellular Algae.]

Fam. 3. CHRYSOMONADINA, Bütschli. Single or colony-forming; seldom an envelope. Spherical free-swimming colonies may be formed by grouping of numerous individuals around a centre. With two or rarely one brown or greenish brown chromatophor; a stigma (eye-speck) at the base of the flagella.

Genera.—*Stylochrysalis*, Stein; *Chrysopyxis*, Stein; *Nephroselmis*, Stein; *Synura*, Ehr.; *Syncrypta*, Ehr. (Fig. XX. 4).

Fam. 4. CHLAMYDOMONADINA. Fore-end of the body with two or four (seldom five) flagella. Almost always green in consequence of the presence of a very large single chromatophor. Generally a delicate shell-like envelope of membranous consistence. 1 to 2 contractile vacuoles at the base of the flagella. Usually one eye-speck. Division of the protoplasm within the envelope may produce four, eight, or more new individuals. This may occur in the swimming or in a resting stage. Also by more continuous fission microgonidia of various sizes are formed. Copulation is frequent.

Genera.—*Hymenomonas*, Stein; *Chlorangium*, Stein; *Chlorogonium*, Ehr. (Fig. XX. 6, 7); *Polytoma*, Ehr.; *Chlamydomonas*, Ehr. (Fig. XX. 1, 2, 3); *Hæmatococcus*, Agardh (= *Chlamydococcus*, A. Brann, Stein; *Protococcus*, Cohn, Huxley and Martin; *Chlamydomonas*, Cienkowski); *Carteria*, Diesing; *Spondylomorom*, Ehr.; *Coccomonas*, Stein; *Phacotus*, Perty.

Fam. 5. VOLVOCINA. Colony-building Phytomastigoda, the cell-individuals standing in structure between Chlamydomonas and Hæmatococcus, and always biflagellate. The number of individuals united to form a colony varies very much, as does the shape of the colony. Reproduction by the continuous division of all or of only certain individuals of the colony, resulting in the production of a daughter colony (from each such individual). In some, probably in all, at certain times copulation of the individuals of distinct sexual colonies takes place, without or with a differentiation of the colonies and of the copulating cells as male and female. The result of the copulation is a resting zygospore (also called zygote or oo-spermospore or fertilized egg-cell), which after a time develops itself into one or more new colonies.

Genera.—*Gonium*, O. F. Müller (Fig. XX. 14); *Stephanosphæra*, Cohn; *Pandorina*, Bory de Vinc.; *Eudorina*, Ehr.; *Volvox*, Ehr. (Fig. XX. 18, 20).

[The sexual reproduction of the colonies of the Volvocina is one of the most important phenomena presented by the Protozoa. In some families of Flagellata full-grown individuals become amoeboid, fuse, encyst, and then break up into flagellate spores which develop

simply to the parental form (Fig. XX. 23 to 26). In the Chlamydomonadina a single adult individual by division produces small individuals, so-called "microgonidia." These copulate with one another or with similar microgonidia formed by other adults (as in Chlorogonium, Fig. XX. 7); or more rarely in certain genera a microgonidium copulates with an ordinary individual (macrogonidium). The result in either case is a "zygote," a cell formed by fusion of two which divides in the usual way to produce new individuals. The microgonidium in this case is the male element and equivalent to a spermatozoon; the macrogonidium is the female and equivalent to an egg-cell. The zygote is a fertilized egg-cell, or oo-spermospore. In the colony-building forms we find that only certain cells produce by division microgonidia; and, regarding the colony as a multicellular individual, we may consider these cells as testis-cells and their microgonidia as spermatozoa. In some colony-building forms the microgonidia copulate with ordinary cells of the colony which, when thus fertilized, become encysted as zygotes, and subsequently separate and develop by division into new colonies. In Volvox the macrogonidia are also specially-formed cells (not merely any of the ordinary vegetative cells), so that in a sexually ripe colony we can distinguish egg-cells as well as sperm mother-cells. Not only so, but in some instances (Eudorina and some species of Volvox) the colonies which produce sexual cells can not merely be distinguished from the asexual colonies (which reproduce parthenogenetically), but can be distinguished also *inter se* into male colonies, which produce from certain of their constituent cell-units spermatozoa or microgonidia only, and female colonies which produce no male cells, but only macrogonidia or egg-cells which are destined to be fertilized by the microgonidia or spermatozoa of the male colonies.

The differentiation of the cell-units of the colony into neutral or merely carrying cells of the general body on the one hand and special sexual cells on the other is extremely important. It places these cell-colonies on a level with the Enterozoa (Metazoa) in regard to reproduction, and it cannot be doubted that the same process of specialization of the reproductive function, at first common to all the cells of the cell-complex, has gone on in both cases. The perishable body which carries the reproductive cells is nevertheless essentially different in the two cases, in the Volvocina being composed of equipollent units, in the Enterozoa being composed of units distributed in two physiologically and morphologically distinct layers or tissues, the ectoderm and the endoderm.

The sexual reproduction of the Vorticellidae may be instructively compared with that of the Phytomastigoda; see below.]

Fam. 6. TETRAMITINA. Symmetrical, naked, colourless, somewhat amoeboid forms, with four flagella or three and an undulating membrane. Nutrition animal, but mouth rarely seen.

Genera.—*Collodictyon*, Carter; *Tetramitus*, Perty (Fig. XXI. 11, 14; calycine monad of Dallinger and Drysdale (66)); *Monocercomonas*, Grassi; *Trichomonas*, Donné; *Trichomastix*, Blochmann.

Fam. 7. POLYMASTIGINA. Small, colourless, symmetrical forms. Two flagella at the hinder end of the body and two or three on each side in front. Nutrition animal or saprophytic.

Genera.—*Hexamitus*, Duj. (Fig. XXI. 5); *Megastoma*, Grassi; *Polymastix*, Bütschli.

Fam. 8. TREPOMONADINA, Kent. As Polymastigina, but the lateral anterior flagella are placed far back on the sides.

Genera.—*Trepomonas*, Duj., described recently without name by Dallinger (67).

Fam. 9. CRYPTOMONADINA. Coloured or colourless, laterally compressed, asymmetrical forms; with two very long anterior flagella, placed a little on one side springing from a deep atrium-like groove or furrow (cf. Dinoflagellata and Noctiluca, to which these forms lead).

Genera.—*Cyathomonas*, From.; *Ohlomonas*, Ehr.; *Cryptomonas*, Ehr.; *Oxyrrhis*, Duj.

Fam. 10. LOPHOMONADINA. A tuft of numerous flagella anteriorly. Genus.—*Lophomonas*, Stein (Fig. XXI. 9, connects the Flagellata with the Peritrichous Ciliata).

#### Sub-class II. Choanoflagellata, Saville Kent.

Flagellata provided with an upstanding collar surrounding the anterior pole of the cell from which the single flagellum springs, identical in essential structure with the "collared cells" of Sponges. Single or colony-building. Individuals naked (*Codosiga*), or inhabiting each a cup (*Salpingoeca*), or embedded in a gelatinous common investment (*Proterospongia*).

#### ORDER 1. NUDA, Lankester.

*Characters*.—Individuals naked, secreting neither a lorica (cup) nor a gelatinous envelope.

Genera.—*Monosiga*, S. Kent (solitary stalked or sessile); *Codosiga*, James Clark (united socially on a common stalk or pedicle, Fig. XXI. 3, 4); *Astrosiga*, S. Kent; *Desmarella*, S. Kent.

#### ORDER 2. LORICATA, Lankester.

*Characters*.—Each individual collared-cell unit secretes a horny cup or shell.

FIG. XXI.—Flagellata. 1. *Salpingoeca fusiformis*, S. Kent; one of the Choanoflagellata. The protoplasmic body is drawn together within the goblet-shaped shell, and divided into numerous spores.  $\times 1500$ . 2. Escape of the spores of the same as monoflagellate and swarm-spores. 3. *Codosiga umbellata*, Tatem; one of the Choanoflagellata; adult colony formed by dichotomous growth;  $\times 625$ . 4. A single zooid of the same;  $\times 1250$ . a, nucleus; b, contractile vacuole; c, the characteristic "collar" formed by cuticle on the inner face of which is a most delicate network of naked streaming protoplasm. 5. *Hexamita inflata*, Duj.; one of the Isomastigoda;  $\times 650$ ; normal adult; showing a, nucleus, and b, contractile vacuole. 6, 7. *Salpingoeca urceolata*, S. Kent; one of the Choanoflagellata;—6, with collar extended; 7, with collar retracted within the stalked cup. a, nucleus; b, contractile vacuole. 8. *Polytioma uvella*, MÜLL. sp.; one of the Phytomastigoda. a, nucleus; b, contractile vacuole.  $\times 800$ . 9. *Lophomonas blattarum*, Stein; one of the Isomastigoda, from the intestine of *Blatta orientalis*. a, nucleus. 10. *Bodo lens*, MÜLL.; one of the Heteromastigoda;  $\times 800$ . a, nucleus; b, contractile vacuole; the wavy filament is a flagellum, the straight one is an immobile trailing thread. 11. *Tetramitus euleatus*, Stein; one of the Isomastigoda;  $\times 430$ . a, nucleus; b, contractile vacuole. 12. *Anthophysa vegetans*, O. F. Müller; one of the Monadida;  $\times 800$ . A typical, erect, shortly-branching colony stock with four terminal monad-clusters. 13. Monad cluster of the same in optical section ( $\times 800$ ), showing the relation of the individual monads or flagellate zooids to the stem a. 14. *Tetramitus rostratus*, Perty; one of the Isomastigoda;  $\times 1000$ . a, nucleus; b, contractile vacuole. 15. *Proterospongia Haeckeli*, Saville Kent; one of the Choanoflagellata;  $\times 800$ . A social colony of about forty flagellate zooids. a, nucleus; b, contractile vacuole; c, ambiform zooid sunk

within the common jelly or test (compared by S. Kent to the mesoderm-cells of a sponge colony); *d.* similar zooids multiplying by transverse fission; *e.* normal zooids with their collars contracted; *f.* hyaline macellipodia common test or zoothecium; *g.* individual contracted and dividing into minute flagellate spores (microzooids) comparable to the spermatozoa of a Sperm.

Genera.—*Siphonaria*, James Clark (sedentary, Fig. XXI. 6, 7); *Laguncula*, S. Kent (free swimming); *Polysera*, S. Kent (cups united socially to form a branching zoecium as in Dinobryon).

### ORDER 3. GELATINIGERA, Lankester.

The cells unite to secrete a copious gelatinous investment and form large colonies.

Genera.—*Phalarionium*, Cienk. (Fig. XX. 12); *Proterosporgia*, Saville Kent (Fig. XXI. 15).

[The Choanoflagellata were practically discovered by the American naturalist James Clark (68), who also discovered that the ciliated chambers of Sponges are lined by collared cells of the same peculiar structure as the individual Choanoflagellata, and hence was led to regard the Sponges as colonies of Choanoflagellata. Saville Kent (69) has added much to our knowledge of the group, and by his discovery of Proterosporgia (see Fig. XXI. 15, and description) has rendered the derivation of the Sponges from the Flagellata a tenable hypothesis.]

Further remarks on the Flagellata.—Increased attention has been directed of late years to the Flagellata in consequence of the researches of Cienkowski, Bütschli, James Clark, Saville Kent, and Stein. They present a very wide range of structure, from the simple amoeboid forms to the elaborate colonies of Volvox and Proterosporgia. By some they are regarded as the parent-group of the whole of the Protozoa; but, whilst not conceding to them this position, but removing to the Proteomyxa those Flagellata which would justify such a view, we hold it probable that they are the ancestral group of the mouth-bearing Ciliata, and that the Ciliata and Dinoflagellata have been derived from them. One general topic of importance in relation to them may be touched on here, and that is the nature of the flagellum and its movements. Speaking roughly, a flagellum may be said to be an isolated filament of vibratile protoplasm, whilst a cilium is one of many associated filaments of the kind. The movement, however, of a flagellum is not the same as that of any cilium; and the movement of all flagella is not identical. A cilium is simply bent and straightened alternately, its substance probably containing, side by side, a contractile and an elastic fibril. A flagellum exhibits lashing movements to and fro, and is thrown into serpentine waves during these movements. But two totally distinct kinds of flagella are to be distinguished, viz., (*a.*) the pulvillum, and (*b.*) the tractellum. An example of the pulvillum is seen in the tail of a spermatozoon which drives the body in front of it, as does the tadpole's tail. Such a "pulvillum" is the cause of the movement of the Bacteria. It is never found in the Flagellata. So little attention has been paid to this fact that affinities are declared by recent writers to exist between Bacteria and Flagellata. The flagellum of the Flagellata is totally distinct from the pulvillum of the Bacteria. It is carried in front of the body and draws the body after it, being used as a man uses his arm and hand when swimming on his side. Hence it may be distinguished as a "tractellum." Its action may be best studied in some of the large Euglenoida, such as Astasia. Here it is stiff at the base and is carried rigidly in front of the animal, but its terminal third is reflected and exhibits in this reflected condition swinging and undulatory movements tending to propel the reflected part of the flagellum forward, and so exerting a traction in that direction upon the whole animal. It is in this way (by reflexion of its extremity) that the flagellum or tractellum of the Flagellata also acts so as to impel food-particles against the base of the flagellum where the oral aperture is situated.

Many of the Flagellata are parasitic (some by matricide, see Lewis, 70); the majority live in the midst of putrefying organic matter in sea and fresh waters, but are not known to be active as agents of putrefaction. Dallinger and Drysdale have shown that the spores of Bodo and others will survive an exposure to a higher temperature than do any known Schizomycetes (Bacteria), viz., 256° to 300° Fahr., for ten minutes, although the adults are killed at 160°.

### CLASS III. DINOFLAGELLATA, Bütschli.

Characters.—Coriaceous Protozoa of a bilaterally asymmetrical form, sometimes flattened from back to ventral surface (Diplopesalis, Glenodinium), sometimes from the front to the hinder region (Ceratum, Peridinium), sometimes from right to left (Dinophysis, Amphidinium, Proterocentrum)—the anterior region and ventral surface being determined by the presence of a longitudinal groove and a large flagellum projecting from it. In all except the genus Proterocentrum (Fig. XXII. 6) there is as well as a longitudinal groove a transverse groove (hence Dinifera) in which lies horizontally a second flagellum (Klebs and Bütschli), hitherto mistaken for a girdle of cilia. The transverse groove lies either at the anterior end of the body (Dinophysis, Fig. XXII. 3, 4; Amphidinium) or

at the middle. In Gymnodinium it takes a spiral course. In Polykrikos (a compound metameric form) there are eight independent transverse grooves.

The Dinoflagellata are either enclosed in a cuticular shell (Ceratum, Peridinium, Dinophysis, Diplopesalis, Glenodinium, Proterocentrum, &c.) or are naked (Gymnodinium and Polykrikos). The cuticular membrane (or shell) consists of cellulose or of a similar substance (*cf.* Labyrinthulidae) and not, as has been supposed, of silica, nor of chitin-like substance; it is either a simple crust or perforated by pores, and may be built up of separate plates (Fig. XXII. 10).

The cortical protoplasm contains trichocysts in Polykrikos.

The medullary protoplasm contains often chlorophyll and also diatomin and starch or other amyloid substance. In these cases (Ceratum, some species of Peridinium, Glenodinium, Proterocentrum, *Dinophysis acuta*) nutrition appears to be holophytic. But in others (Gymnodinium and Polykrikos) these substances are absent and food-particles are found in the medullary protoplasm which have been taken in from the exterior through a mouth: in these nutrition is holozoic. In others which are devoid of chlorophyll and diatomin, &c., there is found a vesicle and an orifice connected with the exterior near the base of the flagellum (*cf.* Flagellata, by which water and dissolved or minutely granular food-matter is introduced into the medullary protoplasm (*Proteridinium pellucidum*, Peridinium divergens, Diplopesalis lentacula, Dinophysis loricata). It is important to note that these divergent methods of nutrition are exhibited by different species of one and the same genus, and possibly by individuals of one species in successive phases of growth (*l.*).

No contractile vacuole has been observed in Dinoflagellata.

The nucleus is usually single and very large, and has a peculiar labyrinthine arrangement of chromatin substance.

Transverse binary fission is the only reproductive process as yet ascertained. It occurs either in the free condition (Fig. XXII. 2, or in peculiar horned cysts (Fig. XXII. 8). Conjugation has been observed in some cases (by Stein in Gymnodinium).

Mostly marine, some freshwater. Many are phosphorescent.

The Dinoflagellata are divisible into two orders, according to the presence or absence of the transverse groove.

### ORDER 1. ADINIDA, Bergh.

Characters.—Body compressed laterally; both longitudinal and transverse flagellum placed at the anterior pole; a transverse groove is wanting; a cuticular shell is present.

Genera.—*Proterocentrum*, Ehr. (Fig. XXII. 6, 7); *Euxistella*, Cienk. (= *Dinophysis*, Stein; *Cryptomonas*, Ehr.).

### ORDER 2. DINIFERA, Bergh.

Characters.—A transverse groove is present and usually a longitudinal groove. The animals are either naked or loricate.

Fam. 1. DINORHYNDA, Bergh. Body compressed; the transverse groove at the anterior pole; the longitudinal groove present; longitudinal flagellum directed backwards; loricate.

Genera.—*Dinophysis*, Ehr. (Fig. XXII. 3, 4); *Amphidinium*, Cl. & L.; *Amphidionella*, Stein; *Heterodina*, Stein; *Citharistes*, Stein; *Ornithocercus*, Stein.

Fam. 2. PERIDINIDA, Bergh. Body either globular or flattened; transverse groove nearly equatorial; longitudinal groove narrow or broad; loricate.

Genera.—*Proteridinium*, Bergh; *Peridinium* (Ehr.), Stein (Fig. XXII. 1, 2); *Proterocentrum*, Bergh; *Ceratum*, Schrank (Fig. XXII. 15); *Diplopesalis*, Bergh; *Glenodinium*, Ehr.; *Heterocapsa*, Stein; *Gonyaulax*, Dissing; *Gonioloma*, Stein; *Elepharocapsa*, Ehr.; *Pedicularia*, Stein; *Amphidoma*, Stein; *Oryzarium*, Stein; *Pyrodinium*, Stein; *Pyroplaxia*, Stein; *Ceratocorys*, Stein.

Fam. 3. GYMNOIDINIDA, Bergh. As Peridinida but no lorica (cuticular shell).

Genera.—*Gymnodinium* (Fig. XXII. 5), Stein; *Hemidinium*, Bergh.

Fam. 4. POLYDINIDA, Bütschli. As Gymnodinida, but with several independent transverse grooves.

Genus.—*Polykrikos*, Bütschli.

Further Remarks on the Dinoflagellata.—This small group is at the moment of the printing of the present article receiving a large amount of attention from Bergh (81), Klebs (83), and Bütschli (82), and has recently been greatly extended by the discoveries of Stein (80)—the last work of the great illustrator of the Ciliate Protozoa before his death. The constitution of the cell-wall or cuticle from cellulose, as well as the presence of chlorophyll and diatomin, and the holophytic nutrition of many forms recently demonstrated by Bergh, has led to the suggestion that the Dinoflagellata are to be regarded as plants, and allied to the Diatomaceae and Desmidiaceae. Physiological grounds of this kind have, however, as has been pointed out above, little importance in determining the affinities of Protozoa. Bütschli (82) in a recent very important article has shown in confirmation of Klebs that the Dinoflagellata do not

possess a girdle of cilia as previously supposed, but that the structure mistaken for cilia is a second flagellum which lies horizontally in the transverse groove. Hence the name *Cilioflagellata* is superseded by *Dinoflagellata* (Gr. dinos, the round area where oxen tread out on a threshing floor).

FIG. XXII.—Dinoflagellata and Rhynchoflagellata. N.B. In all these figures the apparent girdle of cilia is, according to Klebs and Bütschli's recent discovery, to be interpreted as an encircling flagellum lying in the transverse groove. 1. *Peridinium uberrimum*, Allman;  $\times 300$  (fresh-water ponds, Dublin). Probably (according to Bütschli) the processes on the surface are not cilia nor flagellum. Both the longitudinal and the transverse groove are well seen. 2. The same species in transverse fission. 3. *Dinophysis orata*, Cl. and L.;  $\times 250$  (salt water, Norwegian coast). 4. *Dinophysis acuminata*, Cl. and L.;  $\times 350$  (salt water, Norwegian coast). 5. *Gymnodinium*, sp.;  $\times 600$ . 6. *Prorocentrum micans*, Ehr.;  $\times 300$  (salt water). 7. Dorsal aspect of the same species. 8, 9. Cysts of *Peridinium*; the contents of 8 divided into eight minute naked Peridinella;  $\times 300$ . 10. Empty cistern of *Ceratium divergens*, Cl. and L.;  $\times 500$ ; showing the form and disposition of its component plates. 11. The same species with the animal contracted into a spherical form. The transverse groove well seen. 12. The same species in the normal state. The apparent girdle of cilia is really an undulating flagellum lying in the transverse groove. 13, 14. Young stages of *Noctiluca miliaris*. n, nucleus; s, the so-called spine (superficial ridge of the adult); a, the big flagellum; the unlettered filament is a flagellum which becomes the oral flagellum of the adult. 15. *Cera-*

*tium tripos*, Müll. The transverse groove well seen. The cilia really are a single horizontal flagellum. 16, 17. Two stages in the transverse fission of *Noctiluca miliaris*, Suriray. n, nucleus; N, food-particles; t, the muscular flagellum. 18. *Noctiluca miliaris*, viewed from the aboral side (after Allman, *Quart. Jour. Mic. Sci.*, 1872). a, the entrance to the atrium or flagellar fossa (=longitudinal groove); b, the superficial ridge; d, the big flagellum (=the transverse groove of *Dinoflagellata*); h, the nucleus. 19. The animal acted upon by iodine solution, showing the protoplasm like the "primordial utricle" of a vegetable cell shrunk away from the structureless firm shell or cutrass. 20. Lateral view of *Noctiluca*, showing a, the entrance to the groove-like atrium or flagellar fossa in which b is placed; c, the superficial ridge; d, the big flagellum; e, the mouth and gullet, in which is seen Krohn's oral flagellum (=the chief flagellum or flagellum of the longitudinal groove of *Dinoflagellata*); f, broad process of protoplasm extending from the superficial ridge e to the central protoplasm; g, duplicature of the shell in connexion with the superficial ridge; h, nucleus.

Bütschli further suggests that the *Dinoflagellata* with their two flagella and their I-shaped combination of longitudinal and transverse grooves may be derived from the *Cryptomonadina* (see p. 858). In the latter a groove-like recess is present in connexion with the origin of the two flagella. Bütschli thinks the large proboscis-like flagellum of *Noctiluca* (*Rhynchoflagellata*) represents the horizontal flagellum of *Dinoflagellata*, whilst the prominent longitudinal flagellum of the *Dinoflagellata* is represented in that animal by the small flagellum discovered by Krohn within the gullet (see Fig. XXII. 20, c). The young form of *Noctiluca* (Fig. XXII. 14) has the longitudinal flagellum still of large size.

The phosphorescence of many *Dinoflagellata* is a further point of resemblance between them and *Noctiluca*.

Bergh has shown that there is a considerable range of form in various species of *Dinoflagellata* (*Ceratium*, &c.), and has also drawn attention to the curious fact that the mode of nutrition (whether holophytic or holozoic) differs in allied species. Possibly it may be found to differ according to the conditions of life in individuals of one and the same species.

The drawings in Fig. XXII. were engraved before the publication of Bütschli's confirmation of Klebs's discovery as to the non-existence of cilia in the transverse groove. The hair-like processes figured by Allman (91) external to the transverse groove in his *Peridinium uberrimum* (Fig. XXII. 1, 2) cannot, however, be explained as a flagellum. Bütschli inclines to the opinion that their nature was misinterpreted by Allman, although the latter especially calls attention to them as cilia, and as rendering his *P. uberrimum* unlike the *Peridinium* of Ehrenberg, in which the cilia (horizontal flagellum) are confined to the transverse groove.

#### CLASS IV. RHYNCHOFLLAGELLATA, Lankester.

*Characters*.—Corticate Protozoa of large size ( $\frac{1}{2}$ th inch) and globular or lenticular form, with a firm cuticular membrane and highly vacuolated (reticular) protoplasm. In *Noctiluca* a deep groove is formed on one side of the spherical body, from the bottom of which springs the thick transversely striated proboscis or "big flagellum." Near this is the oral aperture and a cylindrical pharynx in which is placed the second or smaller flagellum (corresponding to the longitudinal flagellum of *Dinoflagellata*).

Nutrition is holozoic. No contractile vacuole is present; granule-streaming is observed in the protoplasm. An alimentary tract and anus have been erroneously described. The nucleus is spherical and not proportionately large (see for details Fig. XXII. 16 to 20).

Reproduction by transverse fission occurs, also conjugation and, either subsequently to that process or independently of it, a formation of spores (Cienkowski, 87), the protoplasm gathering itself, within the shell-like cuticular membrane, into a cake which divides rapidly into numerous flagellated spores (flagellulæ). These escape and gradually develop into the adult form (Fig. XXII. 13, 14).

The proboscis-like large flagellum is transversely striated, and exhibits energetic but not very rapid lashing movements.

*Noctiluca* is phosphorescent, the seat of phosphorescence being, as determined by Allman (86), the cortical layer of protoplasm underlying the cuticular shell or cell-wall as the primordial cuticle of a vacuolated vegetable cell underlies the vegetable cell-wall.

Genera.—Only two genera (both marine) are known:—*Noctiluca*, Suriray (90) (Fig. XXII. 17–20); *Leptodiscus*, Hertwig (88).

*Further Remarks on the Rhynchoflagellata*.—The peculiar and characteristic feature of *Noctiluca* appears to be found in its large transversely-striated flagellum, which, according to Bütschli, is not the same as the longitudinal flagellum of the *Dinoflagellata*, but probably represents the horizontal flagellum of those organisms in a modified condition; hence the name here proposed—*Rhynchoflagellata*.

*Noctiluca* is further remarkable for its large size and cyst-like form, and the reticular arrangement of its protoplasm, like that of a vegetable cell. This is paralleled in *Trachelius ovum* among the Ciliata (Fig. XXIV. 14), where the same stiffening of the cuticle allows the vacuolation of the subjacent protoplasm to take place. The remarkable *Leptodiscus medusoides* of R. Hertwig (88) appears to be closely related to *Noctiluca*.

It would no doubt be not unreasonable to associate the *Dino-*

flagellata and the Rhynchoflagellata with the true Flagellata in one class. But the peculiarities of the organization of the two former groups is best emphasized by treating them as separate classes derived from the Flagellata. Neither group leads on to the Ciliata or to any other group, but they must be regarded as forming a lateral branch of the family tree of Corticata. The relationship of Noctiluca to Peridinium was first insisted upon by Allman, but has quite recently been put in a new light by Bütschli, who identifies the atrial recess of Noctiluca (Fig. XXII. 20, b) with the longitudinal furrow or groove of the Dinoflagellata, and the large and minute flagella of the former with the transverse and longitudinal flagella respectively of the latter. The superficial ridge c of Noctiluca appears to represent the continuation of the longitudinal groove.

The phosphorescence of the sea, especially on northern coasts, is largely caused by Noctiluca, but by no means exclusively, since Medusæ, Crustaceans, Annelids, and various Protozoa often take part in the phenomenon. Not unfrequently, however, the phosphorescence on the British coasts seems to be solely due to Noctiluca, which then occurs in millions in the littoral waters.

FIG. XXIII. Ciliata. 1. *Stentor polymorphus*, Müller; one of the Heterotricha;  $\times 50$ ; group of trichous band of 2. *Stentor polymorphus*, Müller; one of the Heterotricha;  $\times 50$ ; group of

individuals with the area fringed by the heterotrichous cilia expanded trumpet-wise. 3. *Tintinnus lagenula*, C. and L.; one of the Heterotricha;  $\times 300$ . 4. *Strombidium*, C. and L.; one of the Peritricha;  $\times 200$ . 5. Empty shell of Heterotricha;  $\times 150$ . 6, 7. *Stentor*, the supra-oral lobe seen through the membranous collar. 8, 9. View of the base and of the side of *Trichodina pediculus*, Ehr.; one of the Peritricha;  $\times 300$ . a, nucleus; c, corneous collar; d, mouth. 10. *Spirochaena gemmipara*, Stein; one of the Peritricha;  $\times 350$ . a, nucleus; g, bud. 11. *Vorticella citrina*, Ehr.;  $\times 150$  (Peritricha). At d multiple fission of an individual cell to form "microgonidia". 12. *Vorticella microstoma*, Ehr. (Peritricha);  $\times 300$ . At e eight "microgonidia" formed by fission of a single normal individual. 13. Same species, binary fission. a, elongated nucleus. 14. *Vorticella nebulifera*, Ehr.; free-swimming zooid resulting from fission in the act of detaching itself and swimming away, possessing a posterior circlet of cilia. e, ciliated disk; f, pharynx. 15. *Vorticella microstoma*, Ehr.; normal zooid with two microgonidia (or microzooids) c, d, in the act of conjugation. a, nucleus; b, contractile vacuole; e, ciliated disk; f, pharynx. 16. *Vorticella microstoma*, Ehr., with stalk contracted and body enclosed in a cyst. a, nucleus. 17. *Vorticella nebulifera*, Ehr. a, nucleus; b, contractile vacuole; c, muscular region of the body continuous with the muscle of the stalk; d, pharynx (the basal continuation of the oral vestibule which receives at a higher point the focal excreta and the ejected liquid from the contractile vacuole). 18. *Carchesium spectabile*, Ehr.; retractile colony;  $\times 50$ . 19. Trichocysts of *Epistylis flavicans*, Ehr., as figured by Greeff. 20. *Opercularia stenostoma*, Stein;  $\times 200$ ; n small colony. Observe the ciliation of the oral vestibule and the upstanding ciliate disk (opercular-like). 21, 22. *Pyxicola affinis*, S. K.; one of the stalked loricate Peritricha, in expanded and retracted states. z, the true operculum. 23, 24. *Gyrocoris oxyura*, Stein; one of the free-swimming Peritricha, with spiral equatorial cilia-band;  $\times 250$ . b, contractile vacuole. 25, 26. *Thuricola rufata*, Str. Wright; one of the sessile tubicolous Peritricha. Two individuals are as a result of fission temporarily occupying one tube; u, the valve attached to the tube, like the door of the trap-door spider's nest and the valve of the Gasteropod Clausilium.

#### CLASS V. CILIATA, Ehrenberg (*Infusoria sensu stricto*).

**Characters.**—Corticata of relatively large size, provided with either a single band of cilia surrounding the anteriorly placed oral aperture or with cilia disposed more numerous over the whole surface of the body. The cilia are distinguished from the flagella of Flagellata by their smaller size and simple movements of alternate flexion and erection; they serve always at some period of growth as locomotor organs, and also very usually as organs for the introduction of food particles into the mouth. Besides one larger oblong nucleus a second (the paranucleus) is invariably (?) present (Fig. XXV. 2), or the nucleus may be dispersed in small fragments. Conjugation of equal-sized individuals, not resulting in permanent fusion, is frequent. The conjugated animals separate and their nuclei and paranuclei undergo peculiar changes; but no formation of spores, either at this or other periods, has been decisively observed (Fig. XXV. 8 to 15). Multiplication by transverse fission is invariably observed in full-grown individuals (Fig. XXV. 16), and conjugation appears to take place merely as an interlude in the fissiparous process; consequently young or small Ciliata are (with few exceptions) unknown. Possibly spore-formation may hereafter be found to occur at rare intervals more generally than is at present supposed (Fig. XXIV. 15, 18). A production of microgonidia by rapid fission occurs in some Peritricha (Fig. XXIII. 11, 12, 14, 15), the liberated microgonidia conjugating with the normal individuals, which also can conjugate with one another.

The Ciliata, with rare exceptions (parasites), possess one or more contractile vacuoles (Fig. XXV. 3). They always possess a delicate cuticle and a body-wall which, although constant, in form is elastic. They may be naked and free-swimming, or they may form horny (Fig. XXIII. 21, 25) or siliceous cup-like shells or gelatinous envelopes, and may be stalked and form colonies like those of Choanoflagellata, sometimes with organic connexion of the constituent units of the colony by a branching muscular cord (Vorticellidae). Many are parasitic in higher animals, and of these some are mouthless. All are holozoic in their nutrition, though some are said to combine with this saprophytic and holophytic nutrition.

The Ciliata are divisible into four orders according to the distribution and character of their cilia. The lowest group (the Peritricha) may possibly be connected through some of its members, such as *Strombidium* (Fig. XXIII. 4), with the Flagellata through such a form as *Lophomonas* (Fig. XXI. 9).

In the following synopsis, chiefly derived from Saville Kent's valuable treatise (71), the characters of the families and the names of genera are not given at length owing to the limitation of our space.

#### ORDER 1. PERITRICHIA, Stein (79).

**Characters.**—Ciliata with the cilia arranged in one anterior circlet or in two, an anterior and a posterior; the general surface of the body is destitute of cilia.

##### Sub-order 1. NATANTIA (animals never attached).

##### Fam. 1. TORQUATELLIDÆ.

Genus.—*Torquatella*, Lankester, like *Strombidium*, but the cilia adherent so as to form a vibratile membranous collar (Fig. XXIII. 6, 7).

##### Fam. 2. DICTYOCYSTIDÆ. Animals loricate.

Fam. 3. ACTINOBOLIDÆ. Illoricate, with retractile tentacula.

Fam. 4. HALTERIIDÆ.  
Genera.—*Strombidium*, Cl. & L. (Fig. XXIII. 4); *Halteria*, Dujard., with a supplementary girdle of springing hairs; *Didinium*, Stein, (Fig. XXIV. 19).  
Fam. 5. GYROCORIDÆ.  
Genera.—*Gyrocoris*, Stein, with an equatorial ciliary girdle spirally disposed (Fig. XXIII. 23, 24); *Urocentrum*, Nitzsch, girdle annular.

FIG. XXIV. Ciliata.—1. *Ophaltnopsis septolæ*, Foett.; a parasitic Holotrichous mouthless Ciliate from the liver of the Squid. 2. A similar specimen treated with picric acid, showing a remarkably branched and twisted nucleus; a, in place of several nuclei. 3. *Trichonympha agilis*, Leidy; parasitic in the intestine of the Termites (White Ants);  $\times 600$ . a, nucleus; b, granules (food). 4. *Opalina ranarum*, Purkinje; a Holotrichous mouthless Ciliate parasitic in the Frog's rectum; adult;  $\times 100$ . a, the numerous regularly dispersed nuclei. 5. The same; an individual in process of binary fission. a, nuclei. 6. The same; the process of fission has now reduced the individuals to a relatively small size. 7. Smallest fission-produced fragment encysted, expelled from the Frog in this state and swallowed by Tadpoles. 8. Young uninucleate individual which has emerged from the cyst within the Tadpole, and will now multiply its nuclei and grow to full size before in turn undergoing retrogressive fission. 9. *Anoplophrya naidos*, Duj.; a mouthless Holotrichous Ciliate parasitic in the worm Nais;  $\times 200$ . a, the large axial nucleus; b, contractile vacuoles. 10. *Anoplophrya prolifera*, C. and L.; from the intestine of Ciliello. Remarkable for the adhesion in a metameric series

of incomplete fission-products. a, nucleus. 11. *Amphileptus gigas*, C. and L.; one of the Holotricha;  $\times 100$ . b, contractile vacuoles; c, trichocysts (see Fig. XXIII. 19); d, nucleus; e, pharynx. 12, 13. *Prorodon niveus*, Ehr.; one of the Holotricha;  $\times 75$ . a, nucleus; b, contractile vacuole; c, pharynx with horny fascicular lining. 14. *Trachinus ovum*, Ehr. (Holotricha);  $\times 80$ ; showing the reticulate arrangement of the medullary protoplasm. b, contractile vacuoles; c, the cuticle-lined pharynx. 15, 16, 17, 18. *Ichthyophthirius multifiliis*, Fouquet; one of the Holotricha;  $\times 120$ . Free individual and successive stages of division to form spores. a, nucleus; b, contractile vacuoles. 19. *Didinium nasutum*, Mull.; one of the Peritricha;  $\times 200$ . The pharynx is everted and has seized a *Paramecium* as food. a, nucleus; b, contractile vacuole; c, everted pharynx. 20. *Euplotes charon*, Mull.; one of the Hypotricha; lateral view of the animal when using its great hypotrichous processes, as ambulatory organs. 21. *Euplotes harpa*, Stein (Hypotricha);  $\times 160$ . h, mouth; z, hypotrichous processes (limbs). 22. *Nyctotherus cordiformis*, Stein; a Heterotrichous Ciliate parasitic in the intestine of the Frog. a, nucleus; b, contractile vacuole; c, food particle; d, anus; e, heterotrichous band of large cilia; f, g, mouth; h, pharynx; i, small cilia.

#### Fam. 6. UROCOLARIIDÆ.

Genera.—*Trichodina*, Ehr.; two ciliate girdles; body shaped as a pyramid with circular sucker-like base, on which is a toothed corneous ring (Fig. XXIII. 8, 9); *Licinophora*, Clap.; *Cyclochaeta*, Hat. Jacks.

FIG. XXV. Ciliata (conjugation, etc.). 1. Surface view of Holotrichous Ciliate, showing the disposition of the cilia in longitudinal rows. 2.

Diagrammatic optical section of a Ciliate Protozoan, showing all structures except the contractile vacuoles. *a*, nucleus; *b*, paranucleus (so-called nucleolus); *c*, cortical substance; *D*, extremely delicate entele; *E*, medullary (more fluid) protoplasm; *f*, cilia; *g*, trichocysts; *h*, filaments ejected from the trichocysts; *i*, oral aperture; *k*, drop of water containing food-particles, about to sink into the medullary substance and form a food-vacuole; *l*, *m*, *n*, *o*, food-vacuoles, the successive order of their formation corresponding to the alphabetical sequence of the letters; the arrows indicate the direction of the movement of rotation of the medullary protoplasm; *p*, pharynx. 3. Outline of a Ciliate (Paramæcium), to show the form and position of the contractile vacuoles. 4-7. Successive stages in the periodic formation of the contractile vacuoles. The ray-like vacuoles discharge their contents into the central vacuole, which then itself bursts to the exterior. 8-15. Diagrams of the changes undergone by the nucleus and paranucleus of a typical Ciliate during and immediately after conjugation: *N*, nucleus; *pn*, paranucleus; 8, condition before conjugation; 9, conjugation effected; both nucleus and paranucleus in each animal elongate and become fibrillated; 10, two spherical paranuclei *pn*<sup>2</sup> in each, two dividing or divided nuclei *N*<sup>2</sup>; 11, the spherical paranuclei have become fusiform; 12, there are now four paranuclei in each (*pn*<sup>4</sup> and *pn*<sup>3</sup>), and a nucleus broken into four or even more fragments; 13, the two paranuclei marked *pn*<sup>2</sup> in 12 have united in each animal to form the new nucleus *pn*<sup>4</sup>; the nuclear fragments are still numerous; 14, after cessation of conjugation the nuclear fragments *N* and the two unfused paranuclear pieces *pn*<sup>3</sup> are still present; 15, from a part or all of the fragments the new paranucleus is in process of formation, the new nucleus (*pn*<sup>4</sup> = *N*) is large and elongated. 16. Diagram of a Ciliate in process of transverse fission. 17. Condition of the nucleus *N*, and of the paranucleus *pn* in *Paramæcium aurelia* after cessation of conjugation as observed by Bütschli. 18. *Stylonichia mytilus* (one of the Hypotricha), showing endoparasitic unicellular organisms *b*, formerly mistaken for spores; *a*, nuclei (after conjugation and breaking up).

#### Fam. 7. OPHRYOSCOLECIDÆ.

Genera.—*Astylozoon*, Engelmann; *Ophryoscolex*, Stein.

Sub-order 2. SEDENTARIA, animals always attached or sedentary during the chief part of the life-history.

Fam. 1. VORTICELLIDÆ. Animals ovate, campanulate, or sub-cylindrical; oral aperture terminal, eccentric, associated with a spiral fringe of adoral cilia, the right limb of which descends into the oral aperture, the left limb encircling a more or less elevated protrusible and retractile ciliary disk.

Sub-family 1. Vorticellinæ: animalcules naked.

*a*.—Solitary forms.

Genera.—*Gerda*, Cl. and L.; *Scyphidia*, Dujard.; *Spirochona*, Stein (sessile with peristome in the form of a spirally convolute membranous expansion, Fig. XXIII. 10); *Pyxidium*, Kent (with a non-retractile stalk); *Vorticella*, Linn. (with a hollow stalk in which is a contractile muscular filament).

*b*.—Forming dendroid colonies.

Genera.—*Carchesium*, Ehr. (Fig. XXIII. 18, with contractile stalks); *Zoothamnium*, Ehr. (contractile stalks); *Epistylis*, Ehr. (stalk rigid); *Opercularia*, Stein (stalk rigid, ciliated disk oblique; an elongated peristomial collar, Fig. XXIII. 20).

Sub-family 2. Vaginicolinæ: animalcules secreting firm cup-like or tube-like membranous shells.

Genera.—*Vaginicola*, Lamarck (no internal valve); *Thuricola*, Kent (with a door-like valve to the tube, Fig. XXIII. 25, 26); *Colthurina*, Ehr. (lorica or shell pedicellate; no operculum); *Pyxicola*, Kent (lorica pedunculate, animal carrying dorsally a horny operculum, Fig. XXIII. 21, 22).

Sub-family 3. Ophryidina: animalcules secreting a soft gelatinous envelope.

Genera.—*Ophionella*, Kent; *Ophryidium*, Ehr.

#### ORDER 2. HETEROTRICHIA, Stein.

*Characters*.—A band or spiral or circlet of long cilia is developed in relation to the mouth (the heterotrichous band) corresponding to the adoral circlet of Peritricha; the rest of the body is uniformly beset with short cilia.

*a*.—Heterotrichal band circular.

Genera (selected).—*Tintinnus*, Sphaeræk (Fig. XXIII. 3); *Trichotintopsis*, Cl. and L.; *Codonella*, Haeck. (with a peri-oral fringe of lappet-like processes); *Calceolus*, Diesing.

*b*.—Heterotrichal band spiral.

Genera (selected).—*Stentor*, Oken (Fig. XXIII. 2); *Blepharisma*, Perty (with an undulating membrane along the oral groove); *Spirostomum*, Ehr. (oral groove linear and elongate, Fig. XXIII. 1); *Leucophrys*, Ehr. (oral groove very short).

*γ*.—Heterotrichal band in the form of a simple straight or oblique adoral fringe of long cilia.

Genera (selected).—*Bursaria*, Müller; *Nyctotherus*, Leidy (with well-developed alimentary tract and anus, Fig. XXIV. 22); *Balanitidium*, Cl. and L. (*B. coli* parasitic in the human intestine).

#### ORDER 3. HOLOTRICHIA, Stein.

*Characters*.—There is no special adoral fringe of larger cilia, nor a band-like arrangement of cilia upon any part of the body; short cilia of nearly equal size are uniformly disposed all over the surface. The adoral cilia sometimes a little longer than the rest.

*a*.—With no membraniform expansion of the body wall.

Genera.—*Paramæcium*, Ehr. (Fig. XXV. 1, 2); *Prorodon*, Ehr.

(Fig. XXIV. 13); *Coleps*, Ehr.; *Enchelys*, Ehr.; *Trachelocerca*, Ehr.; *Trachelinus*, Ehr.; *Amphileptus*, Ehr.; *Icthyophthirius*, Fouquet (Fig. XXIV. 15).

*B*.—Body with a projecting membrane, often vibratile.

Genera.—*Ophryoglena*, Ehr.; *Colpidium*, Stein; *Lembus*, Cohn; *Trichonympha*, Leidy (an exceptionally modified form, parasitic, Fig. XXIV. 3).

*γ*.—Isolated parasitic forms, devoid of a mouth.

Genera.—*Opalina*, Purkinje (nuclei numerous, no contractile vacuole, Fig. XXIV. 4 to 8); *Benedenia*, Foett.; *Opalinopsis*, Foett. (Fig. XXIV. 1, 2); *Anoplophrya*, Stein (large axial nucleus, numerous contractile vacuoles in two linear series, Fig. XXIV. 9 to 10); *Haplophrya*, Stein; *Hoplophrya*, Stein.

#### ORDER 4. HYPOTRICHIA, Stein.

*Characters*.—Ciliata in which the body is flattened and the locomotive cilia are confined to the ventral surface, and are often modified and enlarged to the condition of muscular appendages (setæ so-called). Usually an adoral band of cilia, like that of Heterotricha. Dorsal surface smooth or provided with tactile hairs only. Mouth and anus conspicuously developed.

*a*.—Cilia of the ventral surface uniform, fine, and vibratile.

Genera.—*Chilodon*, Ehr.; *Loxodes*, Ehr.; *Dysteria*, Huxl.; *Huzleya*, Cl. and L.

*b*.—Cilia of the ventral surface variously modified as setæ (muscular appendages), styles, or uncini.

Genera.—*Stylonichia*, Ehr. (Fig. XXV. 18); *Oxytricha*, Ehr.; *Euploea*, Ehr. (Fig. XXIV. 20, 21).

*Further remarks on the Ciliata*.—The Ciliata have recently formed the subject of an exhaustive treatise by Mr Savillo Kent (71) which is accessible to English readers. On the other hand Prof. Bütschli has not yet dealt with them in his admirable critical treatise on the Protozoa. Hence a large space has not been devoted in this article to the systematic classification and enumeration of their genera. See (79) and (93).

One of the most interesting features presented by the group is the presence in many of a cell anus as well as a cell mouth (Fig. XXIV. 22, *d*). In those devoid of an anus the undigested remnants of food are expelled either by a temporary aperture on the body-surface or by one opening into the base of the pharynx. In many parasitic Ciliata, as in higher animal parasites, such as the Cestoid worms, a mouth is dispensed with, nutriment being taken by general imbibition and not in the solid form. Many Ciliata develop chlorophyll corpuscles of definite biconcave shape, and presumably have so far a capacity for vegetal nutrition. In *Vorticella viridis* the chlorophyll is uniformly diffused in the protoplasm and is not in the form of corpuscles (72).

The formation of tubes or shells and in connexion therewith of colonies is common among the Peritricha and Heterotricha. The cuticle may give rise to structures of some solidity in the form of hooks or tooth-like processes, or as a lining to the pharynx (Fig. XXIV. 12).

The phenomena connected with conjugation and reproduction are very remarkable, and have given rise to numerous misconceptions. They are not yet sufficiently understood. It cannot be surely asserted that any Ciliate is at the present time known to break up, after encystment or otherwise, into a number of spores, although this was at one time supposed to be the rule. Icthyophthirius (Fig. XXIV. 15 to 18) and some Vorticellæ (76) have been stated, even recently, to present this phenomenon; but it is not impossible that the observations are defective. The only approach to a rapid breaking up into spores is the multiple formation (eight) of microgonidia or microzooids in Vorticellidæ (Fig. XXIII. 11, 12); otherwise the result of the most recent observations appears to be that the Ciliata multiply only by binary fission, which is very frequent among them (longitudinal in the Peritricha, transverse to the long axis in the others).

Several cases of supposed formation of spores within an adult Ciliate and of the production endogenously of numerous "acinetiform young" have been shown to be cases of parasitism, minute unicellular parasites, e.g., parasitic Acinetæ (such as *Sphaerophrya* described and figured in Fig. XXVI.) being mistaken for the young.

The phenomenon of conjugation is frequent in the Ciliata, and is either temporary, followed by a separation of the fused individuals, as in most cases, or permanent, as in the case of the fertilization of normal individuals by the microgonidia of Vorticellidæ.

Since the process of conjugation or copulation is not followed by a formation of spores, it is supposed to have merely a fertilizing effect on the temporarily conjoined individuals, which nourish themselves and multiply by binary fission more actively after the process than before (hence termed "rejuvenescence").

Remarkable changes have been from time to time observed in the nuclei of Ciliata during or subsequently to conjugation, and these were erroneously interpreted by Balbiani (73) as indicating the formation of spermatozoa and ova. The nuclei exhibit at one period great elongation and a distinct fibrillation, as in the dividing

nuclei of tissue cells (compare Fig. I. and Fig. XXV. 9, 11, 17). The fibrillae were supposed to be spermatozooids, and this erroneous view was confirmed by the observation of rod-like Bacteria (*Schizomyxetes*) which in some instances infest the deeper protoplasm of large Ciliata.

The true history of the changes which occur in the nuclei of conjugating Ciliata has been determined by Bütschli (74) in some typical instances, but the matter is by no means completely understood. The phenomena present very great obstacles to satisfactory examination on account of their not recurring very frequently and passing very rapidly from one phase to another. They have not been closely observed in a sufficiently varied number of genera to warrant a secure generalization. The following scheme of the changes passed through by the nuclei must be regarded as necessarily referring to only a few of the larger *Heterotricha*, *Holotricha*, and *Hypotricha*, and is only probably true in so far as details are concerned, even for them. It is at the same time certain that some such series of changes occurs in all Ciliata as the sequence of conjugation.

In most of the Ciliata by the side of the large oblong nucleus is a second smaller body (or even two such bodies) which has been very objectionably termed the nucleolus (Fig. XXV. 8), but is better called the "paranucleus" since it has nothing to do with the nucleolus of a typical tissue-cell. When conjugation occurs and a "syzygium" is formed, both nucleus and paranucleus in each conjugated animal elongate and show fibrillar structure (Fig. XXV. 10). Each nucleus and paranucleus now divides into two, so that we get two nuclei and two paranuclei in each animal. Elongation and fibrillation are then exhibited by each of these new elements and subsequently fission, so that we get four nuclei and four paranuclei in each animal (11, 12). The fragments of the original nucleus (marked N in the figures) now become more dispersed and broken into further irregular fragments. Possibly some of them are ejected (so-called "cell excrement"); possibly some pass over from one animal to the other. Two of the pieces of the four-times-divided paranucleus now reunite (Fig. XXV. 13), and form a largish body which is the new nucleus. The remaining fragments of paranucleus and the broken down nucleus now gradually disappear, and probably as a remnant of them we get finally a few corpuscles which unite to form the new paranucleus (14, 15). The conjugated animals which have separated from one another before the later stages of this process are thus reconstituted as normal Ciliata, each with its nucleus and paranucleus. They take food and divide by binary fission until a new period of conjugation arrives, when the same history is supposed to recur.

The significance of the phenomena is entirely obscure. It is not known why there should be a paranucleus or what it may correspond to in other cells—whether it is to be regarded simply as a second nucleus or as a structurally and locally differentiated part of an ordinary cell-nucleus, the nucleus and the paranucleus together being the complete equivalent of such an ordinary nucleus. An attempt has been made to draw a parallel between this process and the essential features of the process of fertilization (fusion of the spermatic and ovi-cell nuclei) in higher animals; but it is the fact that concerning neither of the phenomena compared have we as yet sufficiently detailed knowledge to enable us to judge conclusively as to how far any comparison is possible. Whilst there is no doubt as to the temporary fusion and admixture of the protoplasm of the conjugating Ciliata, it does not appear to be established that there is any transference of nuclear or paranuclear matter from one individual to the other in the form of solid formed particles.

Conjugation resulting merely in rejuvenescence and ordinary fission activity is observed in many Flagellata as well as in the Ciliata.

A noteworthy variation of the process of binary fission occurring in the parasite *Opalina* deserves distinct notice here, since it is intermediate in character between ordinary binary fission and that multiple fission which so commonly in Protozoa is known as spore-formation. In *Opalina* (Fig. XXIV. 4) the nucleus divides as the animal grows; and we find a great number of regularly disposed separate nuclei in its protoplasm. (The nuclei of many other Ciliata have recently been shown to exhibit extraordinary branched and even "fragmental" forms; compare Fig. XXIV. 2.) At a certain stage of growth binary fission of the whole animal sets in, and growth ceases. Consequently the products of fission become smaller and smaller (Fig. XXIV. 6). At last the fragments contain each but two, three, or four nuclei. Each fragment now becomes encased in a spherical cyst (Fig. XXIV. 7). If this process had occurred rapidly, we should have had a uninucleate *Opalina* breaking up at once into fragments (as a Gregarina does), each fragment being a spore and enclosing itself in a spore-case. The *Opalina ranarum* lives in the rectum of the Frog, and the encysted spores are formed in the early part of the year. They pass out into the water and undergo no change unless swallowed by a Tadpole, in the intestine of which they forthwith develop. From each spore-case escapes a uninucleate embryo (Fig. XXIV. 8), which absorbs nourishment and grows. As it grows its nucleus divides, and so the large multinucleate form from which we started is reattained.

This history has important bearings, not only on the nature of sporulation, but also on the question of the significance of the multinucleate condition of cells. Here it would seem that the formation of many nuclei is merely an anticipation of the retarded fission process.

It is questionable how far we are justified in closely associating *Opalina*, in view of its peculiar nuclei, with the other Ciliata. It seems certain that the worm-parasites sometimes called *Opalina*, but more correctly *Anaplophrya*, &c., have no special affinity with the true *Opalina*. They not only differ from it in having one large nucleus, but in having numerous very active contractile vacuoles (75).

Recently it has been shown, more especially by Gruber (84), that many Ciliata are multinucleate, and do not possess merely a single nucleus and a paranucleus. In *Oxytricha* the nuclei are large and numerous (about forty), scattered through the protoplasm, whilst in other cases the nucleus is so finely divided as to appear like a powder or dust diffused uniformly through the medullary protoplasm (*Trachelocerca*, *Choenia*). Carmine staining, after treatment with absolute alcohol, has led to this remarkable discovery. The condition described by Foettinger (85) in his *Opalinopsis* (Fig. XXIV. 1, 2) is an example of this pulverization of the nucleus. The condition of pulverization had led in some cases to a total failure to detect any nucleus in the living animal, and it was only by the use of reagents that the actual state of the case was revealed. Curiously enough, the pulverized nucleus appears periodically to form itself by a union of the scattered particles into one solid nucleus just before binary fission of the animal takes place; and on the completion of fission the nuclei in the two new individuals break up into little fragments as before. The significance of this observation in relation to the explanation of the proceedings of the nuclei during conjugation cannot be overlooked. It also leads to the suggestion that the animal cell may at one time in the history of evolution have possessed not a single solid nucleus but a finely molecular powder of chromatin-substance scattered uniformly through its protoplasm, as we find actually in the living *Trachelocerca*.

Some of the Ciliata (notably the common *Vorticella*) have been observed to enclose themselves in cysts; but it does not appear that these are anything more than "hypocysts" from which the animal emerges unchanged after a period of drought or deficiency of food. At the same time there are observations which seem to indicate that in some instances a process of spore-formation may occur within such cysts (76).

The differentiation of the protoplasm into cortical and medullary substance is very strongly marked in the larger Ciliata. The food-particle is carried down the gullet by ciliary currents and is forced together with an adherent drop of water into the medullary protoplasm. Here a slow rotation of the successively formed food-vacuoles is observed (Fig. XXV. 2, l, m, n, o), the water being gradually removed as the vacuole advances in position. It was the presence of numerous successively formed vacuoles which led Ehrenberg to apply to the Ciliata the not altogether inappropriate name "*Polygastrica*." The chemistry of the digestive process has not been successfully studied, but A. G. Bonnier (8) has shown that, when particles stained with water-soluble anilin blue are introduced as food into a *Vorticella*, the colouring matter is rapidly excreted by the contractile vacuole in a somewhat concentrated condition.

The differentiation of the protoplasm of Ciliata in some special cases as "muscular" fibre cannot be denied. The contractile filament in the stalk of *Vorticella* is a muscular fibre and not simple undifferentiated contractile protoplasm; that is to say, its change of dimensions is definite and recurrent, and is not rhythmic, as is the flexion of a cilium. (Perhaps in ultimate analysis it is impossible to draw a sharp line between the contraction of one side of a cilium which causes its flexion and the rhythmical contraction of some muscular fibres.) The movements of the so-called "setae" of the *Hypotricha* are also entitled to be called "muscular," as are also the general contractile movements of the cortical substance of large Ciliata. Haeckel (77) has endeavoured to distinguish various layers in the cortical substance; but, whilst admitting that, as in the Gregarina, there is sometimes a distinct fibrillation of parts of this layer, we cannot assent to the general distinction of a "myophane" layer as a component of the cortical substance.

Beneath the very delicate cuticle which, as a mere superficial pellicle of extreme tenuity, appears to exist in all Ciliata we frequently find a layer of minute oval sacs which contain a spiral thread; the threads are everted from the sacs when irritant reagents are applied to the animal (Fig. XXV. 2, g, h). These were discovered by Allman (78), and by him were termed "trichocysts." They appear to be identical in structure and mode of formation with the nematocysts of the *Coelentera* and *Platyhelminia*. Similar trichocysts (two only in number) are found in the spores of the *Myxosporidia* (see *ante*, page 855).

The comparative forms of the nucleus and of the contractile vacuoles, as well as of the general body-form, &c., of Ciliata may

be learnt from an examination of Figs. XXIII., XXIV., XXV., and the explanations appended to them.

# CLASS VI. ACINETARIA, Lankester (*Tentaculifera*, Hurley).

**Characters.**—Highly specialized Corticate Protozoa, probably derived from Ciliata, since their young forms are provided with a more or less complete investment of cilia. They are distinguished by having no vibratile processes on the surface of the body in the adult condition, whilst they have few or many delicate but firm

with its tentacles, and is in the act of sucking out the juices of six examples of the ciliate *Chlorella parvifrons*. 13. *Podophrya elongata*, Cl. and L.; x 150. a, nucleus; b, contractile vacuole. 14. *Hemiphyra Benedini*, Fraip.; x 200; the suctorial tentacles retracted. 15. *Dendrocometes paradoxus*, Stein; x 350. Parasitic on *Gammarus pulex*. a, nucleus; b, contractile vacuole; c, captured prey. 16. A single tentacle of *Podophrya*; x 500. (Seville Kent.) 17-20. *Dendrocoma fadians*, Ehr.:—17, free-swimming ciliated embryo, x 600; 18, earliest fixed condition of the embryo, x 600; 19, later stage, a single tentaculiferous process now developed, x 600; 20, adult colony; c, enclosed ciliated embryo; d, branching stolon; e, more minute reproductive (?) bodies. 21. *Ophryodendron pedicellatum*, Hirsck; x 500.

tentacle-like processes, which are either simply adhesive or tubular and suctorial. In the latter case they are provided at their extremity with a sucker-disk and have contractile walls, whereas in the former case they have more or less pointed extremities. The Acinetaria are sedentary in habit, even if not, as is usual, permanently fixed by a stalk. The nucleus is frequently arborescent. Reproduction is effected by simple binary fission, and by a modified fission (bud-fission) by which (as in Reticularia and Artella) a number of small bud-like warts containing a portion of the branched parental nucleus are nipped off from the parent, often simultaneously (Fig. XXVI. 6). These do not become altogether distinct, but are for a time enclosed by the parental cell each in a sort of vacuole or brood-chamber, where the young Acinetarian develops a coat or band of cilia and then escapes from the body of its parent (Fig. XXVI. 10, 17). After a brief locomotive existence, it becomes sedentary, develops its tentacles, and loses its cilia.

The Acinetaria have one or more contractile vacuoles. Their nutrition is holozoic.

The surface of the body in some cases is covered only by a delicate cuticle, but in other cases a definite membranous shell or cup (often stalked) is produced. Freshwater and marine. See Fraipont (89).

## ORDER 1. SUCTORIA, Kent.

A greater or less proportion or often all of the tentacles are suctorial and terminated with sucker-like expansions.

**Genera.**—*Rhyncheta*, Zenker (stalkless, naked, with only one tentacle; epizoid on Cyclops; Fig. XXVI. 1); *Urnula*, C. and L.; *Spharophrya*, C. and L. (naked, spherical, with distinctly capitate tentacles only; never with a pedicle; parasitic within Ciliata, supposed young; Fig. XXVI. 2-6, 12); *Trichophrya*, C. and L. (as *Spharophrya*, but oblong and temporarily fixed without a pedicle); *Podophrya*, Ehr. (naked, solitary, globose, ovate or elongate, fixed by a pedicle; tentacles all suctorial, united in fascicles or distributed irregularly; Fig. XXVI. 10, 13, 16); *Hemiphyra*, S. Kent (as *Podophrya*, but the tentacles are of the two kinds indicated in the definition of the group; Fig. XXVI. 8, 9, 14); *Podocorythus*, S. Kent (secreting and inhabiting stalked membranous cups or loricae; tentacles of the two kinds); *Solenophrya*, C. and L. (with a sessile lorica; tentacles only suctorial); *Acineta*, Ehr. (as *Solenophrya*, but the lorica is supported on a pedicle; Fig. XXVI. 11); *Dendrocometes*, Stein (cuticle indurated; solitary, sessile, discoid; tentacles peculiar, viz., not contractile, more or less branched, root-like, and perforated at the extremities and suctorial in function; Fig. XXVI. 15). *Dendrocoma*, Ehr. (forming colonies of intimately fused individuals, with a basal adherent protoplasmic stolon and upstanding branches the termination of which bear numerous capitate suctorial tentacles only; Fig. XXVI. 17-20).

## ORDER 2. NON-SUCTORIA, Lankester (= *Adinaria*, Kent).

**Characters.**—Tentacles filiform, prehensile, not provided with a sucker.

**Genera.**—*Ephelusa*, Str. Wright (solitary, naked, pedunculate, with many flexible inversible tentacles); *Adinocorythus*, S. Kent; *Ophryodendron*, C. and L. (sessile, with a long, extensible, anterior proboscis bearing numerous flexible tentacles at its distal extremity; Fig. XXVI. 21); *Acinetopsis*, Robin (ovate, solitary, secreting a stalked lorica; from the anterior extremity of the animal is developed a proboscis-like organ which does not bear tentacles).

**Further remarks on the Acinetaria.**—The independence of the Acinetaria was threatened some years ago by the erroneous view of Stein (79) that they were phases in the life-history of Vorticellidae. Small parasitic forms (*Spharophrya*) were also until recently regarded erroneously as the "acinetiform young" of Ciliata.

They now must be regarded as an extreme modification of the Protozoan series, in which the differentiation of organs in a unicellular animal reaches its highest point. The sucker-tentacles of the Suctoria are very elaborately constructed organs (see Fig. XXVI. 16). They are efficient means of seizing and extracting the juices of another Protozoan which serves as food to the Acinetarian. The structure of *Dendrocoma* is remarkable on account of its multicellular character and the elaborate differentiation of the reproductive bodies.

The ciliation of the embryos or young forms developed from the buds of Acinetaria is an indication of their ancestral connexion with the Ciliata. The cilia are differently disposed on the young of the various genera (see Fig. XXVI. 10, 17).

FIG. XXVI.—Acinetaria. 1. *Rhyncheta cyclopum*, Zenker. a, nucleus; b, contractile vacuole; only a single tentacle, and that suctorial; x 150. Parasitic on Cyclops. 2. *Spharophrya urotyle*, Mappas; normal adult; x 200. a, nucleus; b, contractile vacuole. Parasitic in Urotyla. 3. The same dividing by transverse fission, the anterior moiety with temporarily developed cilia. a, nucleus; b, contractile vacuole. 4, 5, 6. *Spharophrya r'endren*, Mappas; x 200. Parasitic in Stentor, and at one time mistaken for its young. 7. *Trichophrya epistolidu*, Cl. and L.; x 150. a, nucleus; b, contractile vacuole. 8. *Hemiphyra genantiana*, Hertwig; x 400. Example with six buds, into each of which a branch of the nucleus a is extended. 9. The same species, showing the two kinds of tentacles (the suctorial and the pointed), and the contractile vacuoles b. 10. Ciliated embryo of *Podophrya* Stein, Cl. and L.; x 600. 11. *Acineta grandis*, Seville Kent; x 100; showing pedunculated lorica, and animal with two bunches of entirely suctorial tentacles. a, nucleus. 12. *Spharophrya magna*, Mappas; x 200. It has seized

Anat.", x., Supplement, 1874.

PROUDHON, PIERRE JOSEPH (1809-1865), a well-known revolutionary writer, was born in 1809 at Besançon, France, the native place also of the socialist Fourier. His origin was of the humblest, his father being a brewer's cooper; and the boy herded cows and followed other simple pursuits of a like nature. But he was not entirely self-educated; at sixteen he entered the college of his native place, though his family was so poor that he could not procure the necessary books, and had to borrow them from his mates in order to copy the lessons. There is a story of the young Proudhon returning home laden with prizes, but to find that there was no dinner for him. At nineteen he became a working compositor; afterwards he rose to be a corrector for the press, reading proofs of ecclesiastical works, and thereby acquiring a very competent knowledge of theology. In this way also he came to learn Hebrew, and to compare it with Greek, Latin, and French; and it was the first proof of his intellectual audacity that on the strength of this he wrote an "Essai de grammaire générale." As Proudhon knew nothing whatever of the true principles of philology, his treatise was of no value. In 1838 he obtained the *pension Suard*, a bursary of 1500 francs a year for three years, for the encouragement of young men of promise, which was in the gift of the academy of Besançon. In 1839 he wrote a treatise "On the Utility of Keeping the Sunday," which contained the germs of his revolutionary ideas. About this time he went to Paris, where he lived a poor, ascetic, and studious life,—making acquaintance, however, with the socialistic ideas which were then fomenting in the capital. In 1840 he published his first work *Qu'est-ce que la Propriété?* His famous answer to this question, "La propriété, c'est le vol," naturally did not please the academy of Besançon, and there was some talk of withdrawing his *pension*; but he held it for the regular period.

For his third memoir on property, which took the shape of a letter to the Fourierist, M. Considérant, he was tried at Besançon but was acquitted. In 1846 he published his greatest work, the *Système des Contradictions économiques ou Philosophie de la Misère*. For some time Proudhon carried on a small printing establishment at Besançon, but without success; afterwards he became connected as a kind of manager with a commercial firm at Lyons. In 1847 he left this employment, and finally settled in Paris, where he was now becoming celebrated as a leader of innovation. He regretted the sudden outbreak of the revolution of February (1848), because it found the social reformers unprepared. But he threw himself with ardour into the conflict of opinion, and soon gained a national notoriety. He was the moving spirit of the *Représentant du Peuple* and other journals, in which the most advanced theories were advocated in the strongest language; and as member of assembly for the Seine department he brought forward his celebrated proposal of exacting an impost of one-third on interest and rent, which of course was rejected. His attempt to found a bank which should operate by granting gratuitous credit was also a complete failure; of the five million francs which he required only seventeen thousand were offered. The violence of his utterances led to an imprisonment at Paris for three years, during which he married a young working woman. As Proudhon aimed at economic rather than political innovation, he had no special quarrel with the second empire, and he lived in comparative quiet under it till the publication of his work, *De la Justice dans la Révolution et dans l'Eglise* (1858), in which he attacked the church and other existing institutions with unusual fury. This time he fled to Brussels to escape imprisonment. On his return to France his health broke down, though he continued to write. He died at Passy in 1865.

Personally Proudhon was one of the most remarkable figures of modern France. His life was marked by the severest simplicity and even Puritanism; he was affectionate in his domestic relations, a most loyal friend, and strictly upright in conduct. He was strongly opposed to the prevailing French socialism of his time because of its utopianism and immorality; and, though he uttered all manner of wild paradox and vehement invective against the dominant ideas and institutions, he was remarkably free from feelings of personal hate. In all that he said and did he was the son of the people, who had not been broken to the usual social and academic discipline; hence his roughness, his one-sidedness, and his exaggerations; but he is always vigorous, and often brilliant and original.

It would of course be impossible to reduce the ideas of such an irregular thinker to systematic form. In later years Proudhon himself confessed that "the great part of his publications formed only a work of dissection and ventilation, so to speak, by means of which he slowly makes his way towards a superior conception of political and economic laws." Yet the groundwork of his teaching is clear and firm; no one could insist with greater emphasis on the demonstrative character of economic principles as understood by himself. He strongly believed in the absolute truth of a few moral ideas, with which it was the aim of his teaching to mould and suffuse political economy. Of these fundamental ideas, justice, liberty, and equality were the chief. What he desiderated, for instance, in an ideal society was the most perfect equality of remuneration. It was his principle that service pays service, that a day's labour balances a day's labour—in other words, that the duration of labour is the just measure of value. He did not shrink from any of the consequences of this theory, for he would give the same remuneration to the worst mason as to a Phidias; but he looks forward also to a period in human development when the present inequality in the talent and capacity of men would be reduced to an inappreciable minimum. From the great principle of service as the equivalent of service is derived his axiom that property is the right of *aubaine*. The *aubain* was a stranger not naturalized; and the right of *aubaine* was the right in virtue of which the sovereign claimed the goods of such a stranger who had died in his territory. Property is a right of the same nature, with a like power of appropriation in the form of rent, interest, &c. It reaps without labour, consumes without producing, and enjoys without exertion. Proudhon's aim, therefore, was to realize a science of society resting on principles of justice, liberty, and equality thus understood; "a science absolute, rigorous, based on the nature of man and of his faculties, and on their mutual relations; a science which we have not to invent, but to discover." But he saw clearly that such ideas with their necessary accompaniments could only be realized through a long and laborious process of social transformation. As we have said, he strongly detested the prurient immorality of the schools of Saint-Simon and Fourier. He attacked them not less bitterly for thinking that society could be changed off-hand by a ready-made and complete scheme of reform. It was "the most accursed lie," he said, "that could be offered to mankind." In social change he distinguishes between the transition and the perfection or achievement. With regard to the transition he advocated the progressive abolition of the right of *aubaine*, by reducing interest, rent, &c. For the goal he professed only to give the general principles; he had no ready-made scheme, no utopia. The positive organization of the new society in its details was a labour that would require fifty Montesquieus. The organization he desired was one on collective principles, a free association which would take account of the division of labour, and which would maintain the personality both of the man and the citizen. With his strong and fervid feeling for human dignity and liberty, Proudhon could not have tolerated any theory of social change that did not give full scope for the free development of man. Connected with this was his famous paradox of *anarchy*, as the goal of the free development of society, by which he meant that through the ethical progress of men government should become unnecessary. "Government of men by man in every form," he says, "is oppression. The highest perfection of society is found in the union of order and *anarchy*."

Proudhon's theory of property as the right of *aubaine* is substantially the same as the theory of capital held by Marx and most of the later socialists. Property and capital are defined and treated as the power of exploiting the labour of other men, of claiming the results of labour without giving an equivalent. Proudhon's famous paradox, "*La propriété, c'est le vol*," is merely a trenchant expression of this general principle. As slavery is assassination inasmuch as it destroys all that is valuable and desirable in human personality, so property is theft inasmuch as it appropriates the value produced by the labour of others in the form of rent, interest, or profit without rendering an equivalent. For property Proudhon would substitute individual possession, the right of occupation being equal for all men (see SOCIALISM).

The principal works of Proudhon have already been mentioned. A complete edition, including his posthumous writings, was published at Paris, 1875. See *P. J. Proudhon, sa vie et sa correspondance*, by Sainte-Beuve (Paris, 1875), an admirable work, unhappily not completed; also *Recueil des Deux Mondes*, Jan. 1866 and Feb. 1873.

(T. E.)

PROUT, SAMUEL (1783–1852), water-colour painter, was born at Plymouth on September 17, 1783. His education in art was obtained by a patient and enthusiastic study of nature. He spent whole summer days, in company with the ill-fated Haydon, in drawing the quiet cottages, rustic bridges, and romantic water-mills of the beautiful valleys of Devon. He even made a journey through Cornwall, to try his hand in furnishing sketches for Britton's *Beauties of England*. On his removal in 1803 to London, which became his headquarters after 1812, a new scene of activity opened up before Prout. He now endeavoured to correct and improve his style by the study of the works of the rising school of landscape. To gain a living he painted marine pieces for Palsor the printseller, received pupils, and published many drawing books for learners. He was likewise one of the first who turned to account in his profession the newly-invented art of lithography. In spite of all this industry, however, it was not until about 1818 that Prout discovered his proper sphere. Happening at that time to make his first visit to the Continent, and to study the quaint streets and market-places of Continental cities, he suddenly found himself in a new and enchanting province of art. All his faculties, having found their congenial element, sprung into unwonted power and activity. His eye readily caught the picturesque features of the architecture, and his hand recorded them with unsurpassed felicity and fine selection of line. The composition of his drawings was exquisitely natural; their colour exhibited "the truest and happiest association in sun and shade"; the picturesque remnants of ancient architecture were rendered with the happiest breadth and largeness, with the heartiest perception and enjoyment of their time-worn ruggedness; and the solemnity of great cathedrals was brought out with striking effect. Encouraged by this success, Prout continued most enthusiastically to pursue that path upon which he had unexpectedly come. At the time of his death, 10th February 1852, there was scarcely a nook in France, Germany, Italy, and the Netherlands where his quiet, benevolent, observant face had not been seen searching for antique gables and sculptured pieces of stone. In Venice especially there was hardly a pillar which his eye had not lovingly studied and his pencil had not dexterously copied.

See a memoir of Prout, by John Ruskin, in *Art Journal* for 1849, and the same author's *Notes on the Fine Art Society's Loan Collection of Drawings by Samuel Prout and William Hunt*, 1879–80.

## PROVENÇAL LANGUAGE AND LITERATURE.

I. LANGUAGE.—Provençal is a name used to comprehend all the varieties of Romanic speech formerly spoken and written, and still generally used by country people, in the south of France. The geographical limits of this infinitely varied idiom cannot be defined with precision, because it is conterminous on the north, south, and east with idioms of the same family, with which almost at every point it blends by insensible gradations. Roughly speaking, it may be said to be contained between the Atlantic on the west, the Pyrenees and Mediterranean on the south, and the Alps on the east, and to be bounded on the north by a line proceeding from the Gironde to the Alps, and passing through the departments of Gironde, Dordogne, Haute Vienne, Creuse, Allier, Loire, Rhone, Isère, and Savoie. These limits are to some extent conventional. True, they are fixed in accordance with the mean of linguistic characters; but it is self-evident that according to the importance attached to one character or another they may be determined differently.

1. *Different Names*.—Though the name Provençal is generally adopted to designate the Romanic idiom of this region, it must not be supposed that this name has been

imposed by general *consensus*, or that it rests upon any very firm historical basis. In the southern part of Gaul, Romanic developed itself, so to say, in the natural state of language. Contrary to what took place in other Romanic countries, no local variety here raised itself to the rank of the literary idiom *par excellence*. While in Italy the Florentine, in France the French dialect proper (that is to say, the dialect of the Île de France), succeeded little by little in monopolizing literary use, to the exclusion of the other dialects, we do not find that either the Marseillais or the Toulousain idiom was ever spoken or written outside of Marseilles or Toulouse. In consequence of this circumstance, no name originally designating the language of a town or of a small district came to be employed to designate the language of the whole of southern France; and on the other hand the geographical region described above, having never had any special name, was not able to give one to the idiom.

In the Middle Ages the idiom was spoken of under various appellations: *Romans* or *lenga Romana* was that most generally used. It is notably that employed by the authors of the *Leys d'Amors*, a treatise on grammar, poetry, and rhetoric, composed at Toulouse in the 14th century. But this term, which is capable of being applied, and which, in fact, has been applied, to each of the Romanic languages individually, is too general to be retained. It is, however, that which was revived in the beginning of the present century by Raynouard, the author of the *Lexique roman*. It is now abandoned. In the 13th century a poet born in Catalonia, on the southern slope of the Pyrenees, Raimon Vidal of Besalú, introduced the name of *Limousin* language, probably on account of the great reputation of some Limousin troubadours, but he took care to define the expression, which he extended beyond its original meaning, by saying that in speaking of *Limousin* he must be understood to include Saintonge, Quercy, Auvergne, &c. (*Rasos de trobar*, ed. Stengel, p. 70). This expression found favour in Spain, and especially in Catalonia, where the little treatise of Raimon Vidal was extensively read. The most ancient lyric poetry of the Catalans (13th and 14th centuries), composed on the model of the poetry of the troubadours, was often styled in Spain *poesia lemosina*, and in the same country *lengua lemosina* long designated at once the Provençal and the old literary Catalan.

The name Provençal as applied to language is hardly met with in the Middle Ages, except in the restricted sense of the language of Provence proper, i.e., of the region lying south of Dauphiné on the eastern side of the Rhone. Raimon Ferat, who composed, about 1300, a versified life of St Honorat, uses it, but he was himself a native of Provence. We can also cite the title of a grammar, the *Donatz Proensals*, by Hugh Faidit (about 1250); but this work was composed in north Italy, and we may conceive that the Italians living next to Provence employed the name Provençal somewhat vaguely without inquiring into the geographical limits of the idiom so called. In fact the name Provençal became traditional in Italy, and in the beginning of the 16th century Bembo could write, "Era per tutto il Ponente la favella *Provenzale*, ne tempi ne quali ella fiorì, in prezzo et in istima molta, et tra tutti gli altri idiomi di quelle parti, di gran lunga primiera. Conciosiacosa che ciascuno, o Francese, o Fiamingo, o Guascone, o Borgognone, o altramente di quelle nationi che egli si fosse, il quale bene scrivere e specialmente verseggiar volesse, quantunque egli Provenzale non fosse, lo faceva Provenzalmente" (*Prose*, ed. 1529, fol. viii.).<sup>1</sup>

<sup>1</sup> "The Provençal speech in the times in which it flourished was prized and held in great esteem all over the West, and among all the other idioms of that region was by far the foremost: so that every one,

This passage, in which the primacy of the Provençal tongue is manifestly exaggerated, is interesting as showing the name Provençal employed, though, with little precision, in the sense in which we now apply it.

Another designation, which is supported by the great authority of Dante, is that of *langued'oc*. In his treatise *De Vulgari Eloquentia* (bk i. chaps. viii. and ix.), the Florentine poet divides the languages of Latin origin into three idioms, which he characterizes by the affirmative particles used in each, *oc*, *oïl*, *si*; "nam alii *oc*, alii *oïl*, alii *si* affirmando loquuntur, ut puta Hispani, Franci, et Latini." As is seen, he attributes the affirmation *oc* to the Spaniards, which is of course erroneous, but there is no doubt that to the Spaniards he joined more correctly the inhabitants of southern France, for in the *Vita nuova*, chap. xxv., he speaks of the *lingua d'oc* as having been long celebrated for its poets, which can apply only to the language of the troubadours. The name *langued'oc* occurs also as early as the end of the 13th century, in public acts, but with a different sense, that of the province of Languedoc, as constituted after the union of the county of Toulouse to the French king's dominion in 1271. In the royal acts of the end of the 13th and of the 14th century *partes linguæ occitanæ* or *pays de langue d'oc* designates the union of the five seneschalates of Périgueux, Carcassonne, Beaucaire, Toulouse, and Rhodéz, that is to say, the province of Languedoc, such as it existed till 1790. Some scholars, following the example of Dante, still actually use the term *langued'oc* in opposition to *langued'oui*, but these names have the inconvenience that they take such a secondary fact as the form of the affirmative particle as an essential character. Moreover it can hardly help to distinguish the other Romanic languages, as *langued'si* would cause a confusion between Italian and Spanish. Provençal, without being entirely satisfactory, since in principle it applies solely to the language of Provence, is, notwithstanding, the least objectionable name that can be adopted. In addition to its being in some sort consecrated by the use made of it by the Italians, who were the first after the Renaissance to study the works of the troubadours, it must not be forgotten that, just as the Roman *Provincia*, in which the name originated, extended across the south of Gaul from the Alps to Toulouse and the Pyrenees, so still in the Middle Ages *Provincia*, *Provinciales*, were understood in a very wide sense to designate not only Provence strictly so called, i.e., the present departments of Alpes Maritimes, Basses Alpes, Var, Bouches du Rhône, but also a very considerable part of Languedoc and the adjacent countries. Thus in the 12th century the chronicler Albert of Aix-la-Chapelle (Albertus Aquensis) places the town of Puy (Haute Loire) in *Provincia*.

2. *General Characters of the Language in its Ancient State.*—The Provençal language, within the limits above indicated, cannot be said to have any general characters really peculiar to it. Such of its characters as are found in all the varieties of the language are met with also in neighbouring idioms; such as are not found elsewhere are not general characters, that is to say, are manifested only in certain varieties of Provençal. In reality "Provençal language" does not designate, properly speaking, a linguistic unity; it is merely a geographical expression.

*Tonic or Accented Vowels.*—Latin *a* is preserved in an open syllable *amāre*, *amar*, *amātum*, *amat*, as well as in a closed syllable *car-nem*, *car-ni*. This character is common also to the Romanic of Spain and Italy; but it is one of the best distinguishing marks between Provençal and French, for, to the north, this *a*, when in an open syllable, does not pass beyond a line which

whether Frenchman, Fleming, Gascon, Burgundian, or of what nation soever, who wished to write and versify well, although he was not a Provençal, did it in the Provençal language."

would run approximately through Blaye, Contras (Gironde), Ribérac, Nontron (Dordogne), Bellac (Haute Vienne), Boussac (Creuse), Montluçon, Gannat (Allier), Montbrison (Loire). Starting eastward from Lyons or thereabouts, there appears a notable linguistic fact which is observable in varied proportions in the departments of Ain, Isère, and Savoie, and in Romanic Switzerland. This is, that accented Latin *a* in an open syllable, when preceded by a *mouillure* or palatalization (whatever the origin of this), becomes *e*; on the contrary, when there is no *mouillure*, it remains *a*. Thus we find in the *Meditations* of Marguerite d'Oingt (Lyons, about 1300) *ensennier, delcittier*, as against *desirrar, recomlar, regardar*. Of these two endings, the former, *-ier*, is that which is found regularly in French, the second that which is regular in Pr. Pure Pr. would have *-ar* in both cases (*ensennar, delcitar, desirrar*, &c.); Fr. would have *-ier* (*enseigner, delciter*) and *-er* (*desirer*). Prof. Ascoli has given the name of *Franco-provençal* (*franco-provenzale*) to the varieties of Romanic in which we find this duality of treatment of Latin *a*, according as it was or was not preceded by a palatalized sound. Lat. *ē, ī* become close *e* (Ital., *e chiusa*; Fr. *é*): *habere aver, credere cre, mē(n)sem mes, fidem fe, pīnm pel*. This character is not only common to Italian and Spanish, but also extends over the French domain on its western side as far as Brittany. Certain exceptions noticed in French do not occur in Pr.: thus *mercēdem, cēra, pr(eh)ē(n)sum, venēnum*, which give in Fr. *merci, cire, pris, venin*, where we should have expected *mercei, esire, preis, venciain*, give regularly in Pr. *meres, cera, pres, tere*. Lat. *ē* preserves, as in Italy, the sound of open *e* (Ital., *e aperto*): *pēdem, pe, lēvat, lera, lēporem, lebre*. In certain determinate cases, this *e* from about the 13th century onwards may diphthongize to *ie*: *ēgo, eu*, then *ieu, hēri, er, ier, fērit, fer, fier*. Lat. *ī* is preserved, as in all the Romanic languages: *amicum, ami, rīpa, rība*. Lat. *ī* is treated like *ī* long when it precedes (with hiatus) another vowel: *pīum, pia, piū, pia, rīa, ria, ligat, lia*. Lat. *ū, ū* result in one and the same sound, that of Italian *u*, Fr. *ou* (Eng. *oo*). The same phenomenon takes place in the north of Italy, and in the Romanic of Switzerland. This sound, which is styled by the *Donat Provençal* the *o estreil* (close *o*), is usually symbolized in the early texts by simple *o*, and is thus confounded in spelling, though not in pronunciation, with the open *o* (*o larc* of the *Donat Provençal*), which comes from Lat. *ō*. Lat. *ū* becomes *ū* (i.e., Fr. *u*), as all over France, and also in North Italy and Catalonia: *mūrum, mur* (=mūr), *dūrum, dur* (=dūr). Lat. *au* is rigorously preserved over the whole extent of the Pr. domain: *aurum, aur, alauda, alaūca, pauperem, paubre*. At present the preservation of Lat. *au* does not extend much outside the Prov. domain; it is, however, found in certain parts of the Ladin zone in Switzerland (upper Rhine valley), and in Friuli, and it is to be supposed to have been once general over the whole of that zone. It is attested as late as the 16th century in the Vaudais valleys of Piedmont, and there are also examples of it in old Catalan. Elsewhere the diphthong has regularly become open *o* (*aurum, It. and Sp. oro, Fr. or, &c.*).

**Atonic Vowels.**—The atonic vowels (i.e., vowels of the unaccented syllables) which precede the accented syllable present no very characteristic phenomenon; but it is otherwise with those that follow the accented syllable, the *post-tonic* vowels. The Pr. is one of the Romanic idioms which, like the French, but unlike the Castilian and the dialects of central and northern Italy, admit of only one syllable after the accent. But the rules are not quite the same as in French. In French the only vowel which can stand after the accented syllable is “*e* feminine,” otherwise called “*e* mute.” In Prov. *a* and *e* are the most frequent vowels in this position, but *i* and *o* also occur. In French the first of the two post-tonic vowels of a Lat. proparoxytone always disappears; in Prov. it tends to be preserved, when followed by one of the consonants *n, r, l, d*: *terminum, tērmēn, hominēn, omēn, angelum, a’ngel, se’calem, es’guel, cre’scere, crei’sser, tepidum, te’bez*. Finally, Prov. presents in certain words coming from Lat. proparoxytones the trace of forms which (like Ital.) admitted two atonic vowels after the accented syllable: thus we have *port’gue* and *po’rgue* (po’rticium), *Fabre’ga*, a place name, and *fa’rga* (fa’brica), *perle’ga* and *pe’rga* (pe’rtica), *feme’na* and *fe’mna* (femina). We have also *lagre’ma* (lacryma), but a form accented like Fr. *larme* does not exist. There seems to be no doubt that these forms in which a displacement of the Latin accent is observed were at an earlier period pronounced as proparoxytones (*po’rtigue, fa’brega, pe’rtiga, fe’mena, la’grema*).

**Consonants.**—The boundary usually recognized between Prov. and French is founded upon linguistic characters furnished by the vowels, especially *a*; if it had been determined by characters furnished by the consonants, the line of demarcation would have to be drawn farther south, because the consonantal system which is regarded as proper to French really extends in its main features over the northern zone of the Provençal region as defined above. As with the vowels, only a few of the salient facts can here be

indicated. *C* initial, or second consonant of a group, before *a* (*caballum, mercātum*), preserves its Lat. sound (=k) in the greater part of the Prov. region. But in the northern zone it takes the sound of *ch* (Eng. *ch* in *chin*) as in O. Fr., and this sound is still pretty well preserved, although there is here and there a tendency to the present sound of *ch* in Fr. (=sh Eng.). The place names *Castellum, Castanētum, Casale*, give *Chastel, Chastanel, Chazal*, in Dordogne, Haute Vienne, Corrèze, Puy de Dôme, Cantal, Haute Loire, the north of Lozère, of Ardèche, of Drome, of Isère, and of Hautes Alpes, and *Costel, Castanel, Cazal*, farther to the south. Analogously, *g* initial, or second consonant of a group, followed by *a*, becomes *j* (i.e., *dzh* = O. Fr. and Eng. *j* in *jam*) in the same zone; *Garrica* is *Jarrija, Jarria* in Dordogne, Corrèze, Cantal, Haute Loire, Isère, and *Garriga* farther south. Between two vowels *t* becomes *d*: *edat, emperador, naval, amada* (statem, imperatorem, natale, amata). This was also the case in O. Fr. until the course of the 11th century (*honvredē, emperedur, lavadures, &c.*, in the *Life of St Alexis*). But in the northern zone this *d* representing a Lat. *t* fell away as early as in Fr.; in an 11th-century text from the environs of Valence, we read *muraor, coroa* (\*muratorem, corrogata), Fr. *corée* (P. Meyer, *Recueil d’anciens textes*, Provençal section, No. 40). In the south, *d* between two vowels was preserved almost everywhere until about the middle of the 12th century, when it became *z* (as in Fr. and Eng. *zero*): *crudel, azorar, auzir, zecer* (crudēlem, adorare, audire, videre). In the 14th and 15th centuries this *z*, like every *z* or *s* soft of whatever origin, was liable to become *r* (lingual, not uvular): *ourir, zeren* (audire, videntem). In Béarn and Gascony *d* remained; but in the northern zone Lat. *d*, instead of changing into *z, r*, disappeared as in Fr. and quite as early. The poem of Boetius, of which the MS. is of the 11th century, shows in this respect great hesitation: e.g., *d* preserved in *chaden, credet, trador, rader* (cadentem, \*credēdit, \*tradāre, videre); *d* fallen away in *creessen, fessint, trazo, reūt, fiar* (\*credessent, fidelitatem, \*tradationem, \*vidūtum, p. ple. of videre, fidare). One of the most general facts in Pr. is the habit of rejecting Lat. final *t*, of which examples to any number are presented by the verbs. In Fr. this *t* was formerly retained when it followed a vowel which remained, *aimer, entrat* (amat, intrat), and still remains (in writing at least) when, in Latin, it follows a consonant, *aimet, fait, rit* (amant, facit, \*fact, vivit, \*virit); but in Pr. the *t* is dropped in all cases, even in the most ancient texts: *aman, fai, rit*. Yet in the northern zone we find the *t* retained in the 3d per. pl. of verbs, *-ont, -ont* (Lat. *-ant, -unt*). *H* has gone completely (or at least only appears through orthographic tradition, and very intermittently, (*h*)erto, (*h*)onor, (*h*)umil, &c.), not only in words of Lat. origin, which is the case in O. Fr., but even in Teutonic words (*anta, ardit, arene, avebere, elm, Fr. honte, hardi, hareng, haubert, heaume*, with *h* aspirated). By this feature, the northern limits of which are not yet well determined, the Provençal attaches itself to the Romanic of the southern countries. *N* final, or standing in Lat. between two vowels of which the second is to be dropped, disappears in the whole central part of the Pr. domain: *gran gra, ben be, en e, ven re, fin fi, un u* (granum, bene, in, venit, finem, nnum). The forms with *n* belong to the eastern part (left of the Rhone), the western part (Gascony, but not Béarn), and the region of the Pyrenees. It is possible that this loss of *n* went along with a lengthening of final vowel; at least, in Béarnese when the *n* falls away the vowel is doubled: *caperaa, besit, bo* (capellānum, vicinū, bonum), &c.

These are the most important characteristics of the consonants, in relation to the extent of space over which they prevail. Others, which appear only within a more limited area, are perhaps more curious on account of their strangeness. It will suffice to mention a few which belong to the district bounded on the west and south by the Atlantic, the Basque provinces, and the Pyrenees, and which extends northward and eastward towards the Garonne and its affluents, as far as the Gironde. (This includes Béarn, Bigorre, and Gascony.) Here the sound *r* no longer exists, being replaced generally by *b*; between two vowels, in Gascony, by *u* with the sound of Eng. *u*. Initial *r* assumes a prosthetic *a*: *arram, arre, Arrolbert* (rāmum, rem, Robertum). *Ll* between two vowels becomes *r*: *aperar, aperan*, or (Béarn) *caperaa, bera, era* (apellare, capellanum, hella, ella). On the contrary, at the end of words (viz., in Romanic) *ll* becomes *g* or *t*, *d*; the former change seems to belong rather to Hautes and Basses Pyrénées, Landes, the latter to Gironde, Lot et Garonne, Gers: *eg, ed, el* (ille), *arrasteg, -ed, -et* (rastellum), *casteg, -ed, -et* (castellum), *capdeg, -ed, -et* (capitellum), whence Fr. *cadet* (in 16th century *capdel*, originally a Gascon word). For further details upon the consonants in this region of south-west France, see *Romania*, iii. 435-38, v. 368-69.

**Flexion.**—Old Provençal has, like Old French, a declension consisting of two cases for each number, derived from the Latin nominative and accusative. In certain respects this declension is more in conformity with etymology in Provençal than in Old

French, having been less influenced by analogy. The following are the types of this declension, taking them in the order of the Lat. declensions. 1. Words in -a coming from Lat. 1st decl., increased by certain words coming from Lat. neuter plurals treated in Prov. as feminine singulars; one form only for each number: sing. *causa*, pl. *causars*. 2. Words of the Lat. 2d decl., with a few from the 4th; two forms for each number: sing. subject *cavals* (caballus), object *caval* (caballum); pl. subject *cavals* (caballi), object *cavals* (caballos). 3. Words of Lat. 3d decl. Here there are three Lat. types to be considered. The first type presents the same theme and the same accentuation in all the cases, e.g., *canis*. The second presents the same accentuation in the nominative singular and in the other cases, but the theme differs: *comes*, *comitem*. In the third type the accentuation changes: *peccator*, *peccatorem*. The first type is naturally confounded with nouns of the 2d decl.: sing., subj. *cans* or *cas*, obj. *can* or *ca*. The second and third types are sometimes followed in their original variety; thus *comes* answers to *comos*, and *comite* to *comitem*. But it has often happened that already in vulgar Latin the theme of the nominative singular had been refashioned after the theme of the oblique cases. They said in the nom. sing. *heredis*, *parentis*, *principis*, for *heres*, *parens*, *princeps*. Consequently the difference both of theme and of accentuation which existed in Lat. between nominative and accusative has disappeared in Pr. This reconstruction of the nominative singular after the theme of the other cases takes place in all Lat. words in -as (except *abbas*), in those in -io, in the greater part of those in -or, at least in all those which have an abstract meaning. Thus we obtain *bontatz* (bonitatis for bonitas) and *bontat* (bonitatem), *ciutatz* (civitatis for civitas) and *ciutat* (civitatem), *amors* (amoris for amor) and *amor* (amorem). All present participles in the subject case singular are formed in this way upon refashioned Latin nominatives: *amans* (amantis for amans) *amant* (amantem). It is to be remarked that in regard to feminine nouns Pr. is more etymological than Fr. In the latter feminine nouns have generally only one form for each number; *bonté* for the subj. as well as for the obj. case, and not *bontés* and *bonté*; in Pr. on the contrary *bontatz* and *bontat*. Still, in a large number of nouns the original difference of accentuation between the nominative singular and the other cases has been maintained, whence there result two very distinct forms for the subj. and obj. cases. Of these words it is impossible to give a full list here; we confine ourselves to the exhibition of a few types, remarking that these words are above all such as designate persons: *abais* *abaï*, *pastre* *pastor*, *sor* *soro*, *cantaire* *cantador* (*cantator*, -ōrem), *emperaire* *emperador*, *bar* *baro*, *compañ* *compañho*, *lairo* *lairo* (*latro*, -ōnem). To this class belong various proper names: *Eble* *Ello*, *Gui* *Guio*, *Ue* *Ugo*. A few have even come from the 2d decl., thus *Petire* *Petro*, *Pons* *Ponso*, *Carle* *Carlo*, as if the Latin types had been *Petro*, -ōnem, *Ponso*, -ōnem, *Carlo*, -ōnem. We may mention also geographical adjectives, such as *Bret* *Breto*, *Bergonh* *Bergonho*, *Gase* *Gasco*, &c. The plural of the 3d decl. is like that of the second: subj. *abaï*, *soro*, *cantador*, *emperador*, *baro*, *compañho*, *lairo*; obj. *abaïz*, *soro*, *cantadors*, *emperadors*, *baro*, *compañho*, *lairo*, as if the Lat. nominative pl. had been *abbati*, *sorori*, *cantatori*, &c. It is barely possible that such forms actually existed in vulgar Latin; no trace of them, however, is found in the texts, save in the glosses of Cassel (8th c.), *sapientia* for *sapientes*, and in a great many ancient charters *parentorum*, which implies a nominative *parenti*. The words of the 4th and 5th declensions present no points requiring mention here.

This declension of two cases is a notable character of the whole Romanic of Gaul, north as well as south, i.e., French as well as Provençal. It must be noted, however, that in the south-west it existed only in a very restricted fashion. In the old texts of Gascony it is no longer general in the 13th century. In Béarn it appears to have been completely unknown, the nouns and adjs. having only one form, usually that of the obj. case. In Catalan poetry its application is often laid down in the 13th century, but as the charters and documents free from literary influence show no trace of it, its introduction into the poetry of this country may be assumed to be an artificial fact. In the region where it is best observed, i.e., in the centre and north of the Provençal territory, it tends to disappear from ordinary use already in the 13th century. The poet grammarian Raimon Vidal of Besalú, who flourished about the middle of the century, points out in various troubadours transgressions of the rules of declension, and recognizes that in conversation they are no longer observed. The general tendency was to retain only a single form, that of the obj. case. For certain words, however, it was the subj. form which survived. Thus in modern Pr. the words in the ending -*aire* (answering to Lat. -*ator*) are as frequent as those in -*ador* (repr. -*atorem*). But there is a slight difference of meaning between these two suffixes.

Adjectives, generally speaking, agree in flexion with the nouns. But there is one fact particular to adjectives and past participles which is observed with more or less regularity in certain 12th and

13th century texts. There is a tendency to mark more clearly than in the substantives the flexion of the subj. pl., chiefly when the adj. or participle is employed predicatively. This is marked by the addition of an *i*, placed, according to the district, either after the final consonant, or else after the last vowel so as to form a diphthong with it. The following are examples from an ancient translation of the New Testament (MS. in library of the Palais Saint-Pierre, Lyons, end of 13th century):—"Die a vos quo no siatz *consirosi*" (ne solliciti sitis, Mat. vi. 25); "que siatz *visti d'ols*" (ut videamini ab eis, Mat. vi. 1); "o davant los reis els princeps *seretz menadi*" (et ad presides et ad reges duceamini, Mat. x. 18). In charters of the 12th and 13th centuries we find in the subj. case pl., and especially in this predicative use, *pagaiç*, *certificaiç*, *acossailhaiç*, representing *pagati*, *certificati*, *adconsiliati*.

It is in the verbs that the individuality of the different Romanic idioms manifests itself most distinctly. At a very early date the etymological data were crossed, in various directions and divers manners according to the country, by analogical tendencies. The local varieties became little by little so numerous in the Romanic conjugation that it is not easy to discover any very characteristic features observed over a territory so vast as that of which the limits have been indicated at the commencement of this article. The following are, however, a few.

The infinitives are in -*ar*, -*er*, -*re*, -*ir*, corresponding to the Lat. -*āre*, -*ēre*, -*ere*, -*ire*, respectively: as in the whole Romanic domain, the conjugation in -*ar* is the most numerous. The table of verbs, which forms part of the Pr. grammar called the *Donatz Proensals* (13th century) contains 473 verbs in -*ar*, 101 in -*er* and -*re*, 115 in -*ir*. In the -*ar* conjugation we remark one verb from another conjugation: *far* (cf. It. *fare*) from *facere*. The conjugations in -*er* and -*re* encroach each upon the territory of the other. The three Lat. verbs *cadere*, *capere*, *sapere* have become -*er* verbs (*cader*, *caber*, *saber*) as in Fr. *cheoir*, *cevoir*, *savoir*; and several other verbs waver between the two: *ereder*, *erere*, and *creire* (*cre* *dere*), *querer* and *querre* (*qua* *erre*). This fluctuation is most frequent in the case of verbs which belonged originally to the -*ere* conjugation: *ardere* and *ardre*, *placere* and *plaire*, *lucere* and *lucire* (*ardere*, *placere*, *lucere*). Next to the -*ar* conjugation, that in -*ir* is the one which has preserved most formative power. As in the other Romanic languages, it has welcomed a large number of German verbs, and has attracted several verbs which etymologically ought to have belonged to the conjugations in -*er* and -*re*: *emplir* (im *plere*), *gaudir* (gaudere), *cosir* (consuere), *erchir* (eripere), *fugir* (fugere), *sequir* (\*sequere=sequi).

Except in the -*ar* conjugation, the ending of the infinitive does not determine in a regular manner the mode of forming the different tenses. The present participles are divided into two series: those in -*an* (obj. sing.) for the first conj., those in -*en* for the others. In this the Pr. distinguishes itself very clearly from the French, in which all present participles have -*ant*. There is also in Pr. a participial form or verbal adjective which is not met with in any other Romanic language, except Romanian, where moreover it is employed in a different sense; this is a form in -*dor*, -*doi*, which supposes a Lat. typo -*tōrius*, or -*tūrius*; the sense is that of a future participle, active for the intransitive verbs, passive for the transitive: *enderidior*, -*doi*, "that is to happen"; *fazedor*, -*doi*, "that is to be done"; *punidor*, -*doi*, "to be punished." In conjugation properly so called, we may remark the almost complete disappearance of the Lat. preterite in -*avi*, of which traces are found only in texts written in the neighbourhood of the French-speaking region, and in Béarn. In return, a preterite which seems to have been suggested by the Latin *dēdi*, has increased and become the type of the tense almost everywhere in the -*ar* conjugation, and in many verbs in -*er* and -*re*: *amei*, *amest*, *amet*, *ame'm*, *ame'tz*, *ame'ron*. In Fr. there is a form like this, or at least having the same origin, only in a small number of verbs, none of which belong to the first conjugation, and in these only in the 3rd. pers. sing. and pl. (*perdié*, *perdièrent*; *entendé*, *entendèrent*, &c.) It is well known that reduplicated preterites had greatly multiplied in vulgar Latin: there have been recovered such forms as *ascendiderat*, *ostendedit*, *pandiderunt*, *adattendit*, *incendiderat*, &c. (see Schuchardt, *Vokalismus des Vulgarlateins*, i. 35, iii. 10; cf. *Romania*, ii. 477). But, in order to explain the Pr. form -*ci*, -*est*, -*et* (with open *e*), we must suppose a termination not in -*idi* or -*ēdi*, but in -*ēdi*. In the western region the 3d pers. sing. is generally in -*ec*, probably by analogy with preterites like *bee*, *cec*, *dec*, *sec*, formed after the Lat. type in -*ui*. Another notable peculiarity, of which Old Fr. shows only rare traces, in texts of a very remote period, is the preservation of a preterite in -*ara* or -*era*, derived from the Lat. pluperfect, *ama* *ra* or *ame* *ra*, "I loved." The former comes directly from Lat. *amāram*, the latter has been influenced by the ordinary preterite in -*ei*. This preterite is used with the sense of a simple past, not of a pluperfect, and consequently is an exact doublet of the ordinary preterite, which explains how it was at length eliminated almost everywhere by the latter, of

which it was a mere synonym. But it remained in general use with the sense of a past conditional: *ama'ra* or *ame'ra*, "I should have loved," *fora*, "I should have been."

3. *Existing State of the Provençal.*—In consequence of political circumstances (see notice of Provençal Literature below), the Provençal ceased to be used for administrative as well as literary purposes about the 15th century, in some places a little sooner, in others later (notably in Bearn, where it continued to be written as the language of ordinary use till the 17th century). The poems in local dialect composed and printed in the 16th century and on to our own day have no link with the literature of the preceding period. Reduced to the condition of a *patois*, or popular dialect simply, the idiom experienced somewhat rapid modifications. Any one who should compare the poems of Goudclin of Toulouse (1572-1649) with those of a Toulousain troubadour of the 13th century would be astonished at the changes which the language has undergone. Yet this impression would probably be exaggerated. In order to make a rigorously accurate comparison of the language at the two epochs, it would have to be written in the two cases with the same orthographic system, which it is not. The first writers of Provençal, about the 10th or 11th century, applied to the language the Latin orthography, pre-erring to each letter, as far as possible, the value given to it in the contemporary pronunciation of Latin. To express certain sounds which did not exist in Latin, or which were not there clearly enough noted, there were introduced little by little, and without regular system, various conventional symbolizations such as *li* and *nh* to symbolize the sound of *l* and *n mouille*. From this method of proceeding there resulted an orthographic system somewhat wanting in fixity, but which from its very instability lent itself fairly well to the variations which the pronunciation underwent in time and locality. But the tradition having been interrupted about the 15th century, those who afterwards by way of pastime attempted composition in the *patois* formed, each for himself apart, an orthography of which many elements were borrowed from French usage. It is evident that differences already considerable must be exaggerated by the use of two very distinct orthographical systems. Nevertheless, even if we get quit of the illusion which makes us at first sight suppose differences of sound where there are merely different ways of spelling the same sound, we find that between the 14th and 16th century the language underwent everywhere, Bearn (for reasons already given) excepted, great modifications both in vocabulary and grammar. The Provençal literature having gradually died out during the 14th century, the vocabulary lost immediately the greater part of the terms expressing general ideas or abstract conceptions. To supply the place of these, the authors who have written in the *patois* of the south during the last few centuries have been obliged to borrow from French, modifying at the same time their form, a multitude of vocables which naturally have remained for the most part unintelligible to people who know only the *patois*. In this case the adoption of foreign words was excusable; but it did not stop here. Little by little, as primary instruction (now compulsory) was diffused, and introduced first in the towns and afterwards in the villages a certain knowledge of French, words purely French have been introduced into use in place of the corresponding dialect words. Thus, one hears constantly in Provence *pèro*, *mèro*, *frèro*, forms adapted from French, instead of *paire*, *maire*, *fraire*; *carha* (*cat'har* = Fr. *cacher*) instead of *escondre*, &c.

In the phonology, the modifications are of the natural order, and so have nothing revolutionary. The language has developed locally tendencies which certainly already existed during the flourishing period, although the ancient orthography did not recognize them.

Of the vowels, *a* tonic is generally preserved; *an* in an open syllable becomes *o* (open) in part of the departments of Aveyron, Lot, Dordogne, Correze, Cantal, and south of Haute Loire: *gro* (granum), *mo* (manum), *po* (panem). This nasalized *o* must have had a particular sound already in Old Pr., for it is qualified in the *Donats Provençals* (ed. Stengel, p. 49) as *a estreil* (=close or narrow *a*). A feature almost general is the passage of post-tonic *a* into *o*: *terro*, *amaro*, *amado* (*terra*, *amabat*, *amata*). In Var and the Maritime Alps examples of this change occur as early as the end of the 15th century. But even yet there are a few cantons, notably Montpellier and its neighbourhood, where the ancient post-tonic *a* is preserved. It is remarkable that the Latin diphthong *au*, which had become simple *o* in almost all Romance lands at the date of the most ancient texts, is to this day preserved with a very distinct diphthongal sound everywhere in the south of France.

In the morphology, the leading feature of modern Provençal is the ever greater simplification of grammatical forms. Not only have the two forms (nominative and objective, in each number, in nouns and adjective) been reduced to one—this reduction manifested itself in ordinary use already in the 14th century—but in many places there no longer remains any distinction between the singular and the plural. In a great part of the south *eu* (ego) does duty as an objective, *ni* or *mi* having disappeared. In part of Drôme it is the other way, *ni* being substituted in the nominative for *eu*, which it has completely displaced. It is perhaps in conjugation that the greatest changes from the older form of the language are seen. Analogy, basing itself upon one or another much used form, has acted with immense force, tending to make general in the whole conjugation, without any regard to the original classes to which the various verbs belonged, certain terminations, chiefly those which were accented, and thus appeared to the popular instinct to have more significance. The result, if the tendency were carried the full length, would be the reduction of all the three conjugations to one. Perhaps before this point is reached the *patois* of the south will themselves have disappeared. As the endless modifications which the language undergoes, in vocabulary and grammar alike, develop themselves in different directions, and each over an area differently circumscribed, the general aspect of the language becomes more and more confused, without the possibility of grouping the endless varieties within dialectal divisions, there being no case in which a certain number of phonetic or morphological facts prevent themselves within the same geographical limits. The custom has been adopted of roughly designating these varieties by the name of the ancient provinces in which they appear: *Limousin* (divided into *High* and *Low Limousin*), *Marche*, *Auvergne*, *Gascogne*, *Bearn*, *Roussillon*, *Languedoc*, *Provençal*, &c.; but these divisions, though convenient in use, correspond to no actualities. Nîmes and Montpellier are in Languedoc, and Arles and Tarascon are in Provence; nevertheless the dialect of Nîmes resembles that of Arles and Tarascon more than that of Montpellier.

*Texts*—For the history of the Provençal in all its varieties there are many more materials than for any other Romance language, not excepting even Italian or French. The literary texts go back to the 10th or 11th century (see below). For scientific purposes many of these texts are of secondary value, because the 15th or 16th century have reached us, and several of which, especially for the poetry of the troubadours, are of Italian origin, have altered the original forms to an extent which it is not easy to determine; but we possess a considerable number of charters, contracts, regulations, accounts, registers of taxation, which are worthy of absolute confidence, and, because these documents are in most cases original, and accordingly, because none of the dialectal varieties having raised itself to the rank of the literary language, as happened in France with the central (Parisian) variety and in Italy with the Florentine, writers never had the temptation to borrow from their own dialect for another. It is proper to add that Provençal possesses two ancient grammars of the 13th century (the earliest composed for any Romance language)—the *Donats Provençals* and *Paos de trobar* (see p. 876). Although very short, especially the second, which is a collection of detached observations, they furnish valuable data. The 14th-century *Leys d'Amors* (see p. 876) presents the language in its best artificial state—the language which ought to be written rather than the language actually existing.

*Dictionaries*—1. *Ancient Condition*—There does not exist any comprehensive work upon the Provençal whence to obtain a precise idea of the history of the language at its different epochs. Diez' *Grammatik der romanischen Sprachen* is still the groundwork. It gives, especially in the 3d ed. (1892-72), the latest revised by the author, the results of extensive researches tentatively arranged. But Diez had only a slender knowledge of the language in its present state, and in his time phonology had made little progress. The French translation of 1911 G. Paris, A. Brachet, and Morel Fa'lo (Paris, 1877-76) was to be completed by a supplementary volume, which was announced at vol. ix, p. 676 of the present work, but this expectation has had to be abandoned, it having been recognized that what was wanted was not a supplement but a general recast. The "*Pecherches philologiques sur la langue romane*," and "*Résumé de la grammaire romane*," published by Raynouard at the beginning of vol. I of his *Langue romane* (1835), are entirely out of date. The "*Tableau sommaire des lexiques provençaux*," published by M. Bartsch, in the *Chrestomathie provençale* (4th ed., 1875), is incomplete and often erroneous. The actual state of our knowledge of ancient Provençal must be sought in a great number of scattered disquisitions or monographs, which will be found especially in the *Mémoires de la Société de Linguistique de Paris*, 1868 (*Phonétique provençale*, O pp. 145-61), in the *Romania* (1872-87), and in the *Revue de la Société pour l'étude des langues romanes*, to which may be added some doctoral dissertations published in Germany, and the special studies upon the language of particular texts prefaced to many of these. As to dictionaries, the *Lexique romane, ou Dictionnaire de la langue des Troubadours*, by Raynouard (Paris, 6 vols. 8vo, 1838-44), can always be used with advantage, but the numerous special vocabularies appended by editors to texts published by them cannot be neglected. These yield a considerable

number of words, either wanting or wrongly explained in the *Lexique roman*. 2. *Modern Form*.—The most useful grammatical works (all done with insufficient preconceived idea that there exist dialects) are B. Andrews, *Essai de grammaire du dialecte* (see also his "Phonétique montonaise," in *sur l'orthographe et la prononciation languedociennes*, prefixed to *La Canson de la Lausca*, by A. Mir (Montpellier, 1876); Chobancan, *Grammaire limousine* (Paris, 1876), referring especially to the variety of Nontron, in the north of France; J. Lescap, *Essai sur l'histoire du sous-dialecte du Rouergue béarnaise* (2d ed., Paris, 1880); *sur les idiomes pyrénéens de la région française* (Paris, 1879); Montier, *Grammaire dauphinoise, Dialecte de la vallée de la Drôme* (Montclair, 1882); Ruben, "Étude sur le patois du Haut Limousin," prefixed to *Poems* by J. Foucaud, in the *Limousin patois* (Limoges, 1866). As to dictionaries we may mention, among others, Andrews, *Vocabulaire français-montonais* (Nice, 1877); Azols, *Dictionnaire des idiomes romans du midi de la France* (Montpellier, 1877, 3 vols. 8vo), taking for its basis the dialect of Béziers; Chabrand and De Rochas d'Alghun, *Patois des Alpes Cottiniennes et en particulier du Queyras* (Grenoble and Paris, 1877); Couzinic, *Dictionnaire de la langue romano-castraise* (Castres, 1850); Gorcin, *Nouveau dictionnaire provençal-français* (Digne, 1846-7, 2 vols. 4to); De Sauvages, *Dictionnaire languedocien-français* (new ed., Alais, 1820, 2 vols.); Vayssier, *Dictionnaire patois-français du département de l'Aveyron* (Rodez, 1879). From 1880 the *Dictionnaire provençal-français* of Fr. Mistral, in 2 vols. 4to, has been in progress; more than the half has appeared. This dictionary takes as its basis the variety of Mâlliane (in the north of Bouches-du-Rhône), the author's native district, and gives in as complete a manner as possible all the forms used in the south of France. It is by far the best of all the dictionaries of the southern dialects which have yet been published, and when finished it will almost enable the student to dispense with all the others.

II. PROVENÇAL LITERATURE.—Provençal literature is much more easily defined than the language in which it is expressed. Starting in the 11th and 12th centuries in several centres, it thence gradually spread out, first over the greater portion, though not the whole, of southern France, and then into the north of Italy and Spain. It nowhere merged in the neighbouring literatures. At the time of its highest development (12th century) the art of composing in the vulgar tongue did not exist, or was only beginning to exist, to the south of the Alps and the Pyrenees. In the north, in the country of French speech, vernacular poetry was in full bloom; but between the districts in which it had developed—Champagne, Île de France, Picardy, and Normandy—and the region in which Provençal literature had sprung up, there seems to have been an intermediate zone formed by Burgundy, Bourbonnais, Berry, Touraine, and Anjou which, far on in the Middle Ages, appears to have remained barren of vernacular literature. In its rise Provençal literature stands completely by itself, and in its development it long continued to be absolutely original. It presents at several points genuine analogies with the sister-literature of northern France; but these analogies are due principally to certain primary elements common to both and only in a slight degree to mutual reaction.

It must be inquired, however, what amount of originality could belong to any, even the most original, Romanic literature in the Middle Ages. In all Romanic countries compositions in the vernacular began to appear while the custom of writing in Latin was still preserved by uninterrupted tradition. Even during the most barbarous periods, when intellectual life was at its lowest, it was in Latin that sermons, lives of saints more or less apocryphal, accounts of miracles designed to attract pilgrims to certain shrines, monastic annals, legal documents, and contracts of all kinds were composed. When learning began to revive, as was the case in northern and central France under the influence of Charlemagne and later in the 11th century, it was Latin literature which naturally received increased attention, and the Latin language was more than ever employed in writing. Slowly and gradually the Romanic languages, especially those of France, came to occupy part of the ground formerly occupied by Latin, but even after the Middle Ages had passed away the parent tongue retained no small portions of its original empire. Consequently Romanic literatures in general (and this is especially true of Provençal as it does not extend beyond the mediæval period) afford only an incomplete representation of the intellectual development of each country. Those literatures even which are most truly national, as having been subjected to no external influence, are only to a

limited extent capable of teaching us what the nation was. They were, in short, created in the interests of the illiterate part of the people, and to a considerable degree by those who were themselves illiterate. But that does not make them less interesting.

*Origin*.—It was in the 11th century, and at several places in the extensive territory whose limits have been described in the foregoing account of the Provençal language, that Provençal literature first made its appearance. It took poetic form; and its oldest monuments show a relative perfection and a variety from which it may be concluded that poetry had already received a considerable development. The oldest poetic text, if the date and origin be correctly determined, is said to be a Provençal refrain attached to a Latin poem recently published (*Zeitschrift für deutsche Philologie*, 1881, p. 335) from a Vatican MS., written, it is asserted, in the 10th century. But it is useless to linger over these few words, the text of which seems corrupt, or at least has not yet been satisfactorily interpreted. The honour of being the oldest literary monument of the Provençal language must be assigned to a fragment of two hundred and fifty-seven decasyllabic verses preserved in an Orleans MS. and frequently edited and annotated since it was first printed by Raynouard in 1817 in his *Choix des poésies originales des Troubadours*. The writing of the MS. is of the first half of the 11th century. The peculiarities of the language point to the north of the Provençal region, probably Limousin or Marche. It is the beginning of a poem in which the unknown author, taking Boetius's treatise *De Consolatione Philosophiæ* as the groundwork of his composition, adopts and develops its ideas and gives them a Christian cast of which there is no trace in the original. Thus from some verses in which Boetius contrasts his happy youth with his afflicted old age he draws a lengthy homily on the necessity of laying up from early years a treasure of good works. The poem is consequently a didactic piece composed by a "clerk," knowing Latin. He doubtless preferred the poetic form to prose because his illiterate contemporaries were accustomed to poetry in the vulgar tongue, and because this form was better adapted to recitation; and thus his work, while a product of erudition in as far as it was an adaptation of a Latin treatise, shows that at the time when it was composed a vernacular poetry was in existence. A little later, at the close of the same century, we have the poems of William IX., count of Poitiers, duke of Guienne. They consist of eleven very diverse strophic pieces, and were consequently meant to be sung. Several are love songs; one relates a *bonne fortune* in very gross terms; and the most important of all—the only one which can be approximately dated, being composed at the time when William was setting out for Spain to fight the Saracens—expresses in touching and often noble words the writer's regret for the frivolity of his past life and the apprehensions which oppressed him as he bade farewell, perhaps for ever, to his country and his young son. We also know from Ordericus Vitalis that William IX. had composed various poems on the incidents of his ill-fated expedition to the Holy Land in 1101. And it must further be mentioned that in one of his pieces (*Ben vol que sapeton li plusor*) he makes a very clear allusion to a kind of poetry which we know only by specimens of later date, the *partimen*, or, as it is called in France, the *jeu parti*. William IX. was born in 1071 and died in 1127. There is no doubt that the most prolific period of his literary activity was his youth. On the other hand there is no reason to believe that he created the type of poetry of which he is to us the oldest representative. It is easy to understand how his high social rank saved some of his productions from oblivion whilst the poems of his pre-

deceutors and contemporaries disappeared with the generations who heard and sang them; and in the contrast in form and subject between the Boetius poem and the stanzas of William IX. we find evidence that by the 11th century Provençal poetry was being rapidly developed in various directions. Whence came this poetry? How and by whose work was it formed? That it has no connexion whatever with Latin poetry is generally admitted. There is absolutely nothing in common either in form or ideas between the last productions of classical Latinity, as they appear in Sidonius Apollinaris or Fortunatus, and the first poetic compositions in Romanic. The view which seems to meet with general acceptance, though it has not been distinctly formulated by any one, is that Romanic poetry sprang out of a popular poetry quietly holding its place from the Roman times, no specimen of which has survived,—just as the Romanic languages are only continuations with local modifications of vulgar Latin. There are both truth and error in this opinion. The question is really a very complex one. First as to the form: Romanic versification, as it appears in the Boetius poem and the verses of William IX., and a little farther north in the poem of the *Prison* and the *Life of St Leger* (10th or 11th century), has with all its variety some general and permanent characteristics: it is rhymed, and it is composed of a definite number of syllables certain of which have the syllable accent. This form has evident affinity with the rhythmic Latin versification, of which specimens exist from the close of the Roman empire in ecclesiastical poetry. The exact type of Romanic verse is not found, however, in this ecclesiastical Latin poetry; the latter was not popular, and it may be assumed that there was a popular variety of rhythmic poetry from which Romanic verse is derived.

Again, as regards the substance, the poetic material, we find nothing in the earliest Provençal which is strictly popular. The extremely personal compositions of William IX. have nothing in common with folklore. They are subjective poetry addressed to a very limited and probably rather aristocratic audience. The same may be said of the Boetius poem, though it belongs to the quite different species of edifying literature; at any rate it is not popular poetry. Vernacular compositions seem to have been at first produced for the amusement, or in the case of religious poetry for the edification, of that part of lay society which had leisure and lands, and reckoned intellectual pastime among the good things of life. Gradually this class, intelligent, but with no Latin education, enlarged the circle of its ideas. In the 12th century and still more in the 13th, historical works and popular treatises on contemporary science were composed for its use in the only language it understood; and vernacular literature continued gradually to develop partly on original lines and partly by borrowing from the literature of the "clerks." But in the 11th century vernacular poetry was still rather limited, and has hardly any higher object than the amusement and edification of the upper classes. An aristocratic poetry like the oldest Provençal cannot be the production of shepherds and husbandmen; and there is no probability that it was invented or even very notably improved by William IX.

From what class of persons then did it proceed? Latin chroniclers of the Middle Ages mention as *joculares*, *joculatores*, men of a class not very highly esteemed whose profession consisted in amusing their audience either by what we still call jugglers' tricks, by exhibiting performing animals, or by recitation and song. They are called *joglars* in Provençal, *jouglers* or *jongleurs* in French. A certain Barnaldus, styled *joglarius*, appears as witness in 1058 to a charter of the chartulary of Saint Victor at Marseilles. In 1106 the act of foundation of a *salva terra* in Rouergue

specifies that neither knight nor man-at-arms nor *joculator* is to reside in the village about to be created. These individuals—successors of the *mimi* and the *thymelici* of antiquity, who were professional amusers of the public—were the first authors of poetry in the vernacular both in the south and in the north of France. To the upper classes who welcomed them to their castles they supplied that sort of entertainment now sought at the theatre or in books of light literature. There were certain of them who, leaving buffoonery to the ruder and less intelligent members of the profession, devoted themselves to the composition of pieces intended for singing and consequently in verse. In the north, where manners were not so refined and where the taste for warlike adventure prevailed, the jongleurs produced *chansons de geste* full of tales of battle and combat. In the courts of the southern nobles, where wealth was more abundant and a life of ease and pleasure was consequently indulged in, they produced love songs. There is probably a large amount of truth in the remark made by Dante in chapter xxv. of his *Vita Nuova*, that the first to compose in the vulgar tongue did so because he wished to be understood by a lady who would have found it difficult to follow Latin verses.<sup>1</sup> And in fact there are love songs among the pieces by William of Poitiers; and the same type preponderates among the compositions of the troubadours who came immediately after him. But it is worthy of note that in all this vast body of love poetry there is no epithalamium nor any address to a marriageable lady. The social conditions of the south of France in the feudal period explain in great measure the powerful development of this kind of poetry, and also its peculiar characteristics—the profound respect, the extreme deference of the poet towards the lady whom he addresses. Rich heiresses were married young, often when hardly out of their girlhood, and most frequently without their fancy being consulted. But they seem after marriage to have enjoyed great liberty. Eager for pleasure and greedy of praise, the fair ladies of the castle became the natural patronesses of the *menie* or household of men-at-arms and jongleurs whom their husbands maintained in their castles. Songs of love addressed to them soon became an accepted and almost conventional form of literature; and, as in social position the authors were generally far below those to whom they directed their amorous plaints, this kind of poetry was always distinguished by great reserve and an essentially respectful style. From the beginning the sentiments, real or assumed, of the poets are expressed in such a refined and guarded style that some historians, overestimating the virtue of the ladies of that time, have been misled to the belief that the love of the troubadour for the mistress of his thoughts was generally platonic and conventional.

The conditions under which Romanic poetry arose in the south of France being thus determined as accurately as the scarcity of documents allows, we now proceed to give a survey of the various forms of Provençal literature, chronological order being followed in each instance. By this arrangement the wealth of each form will be better displayed; and, as it is rare in the south of France for the same person to distinguish himself in more than one of them, there will be generally no occasion to introduce the same author in different sections.

*Poetry of the Troubadours.*—Though he was certainly not the creator of the lyric poetry of southern France, William, count of Poitiers, by personally cultivating it gave it a position of honour, and indirectly contributed in a very powerful degree to insure its development and pre-

<sup>1</sup> "E lo primo che comenciò a dire siccome poeta volgare si mosse perche volle fare intendere le sue parole a donna alla quale era malagevole ad intendere i versi latini."

ervation. Shortly after him centres of poetic activity make their appearance in various places—first in Limousin and Gascony. In the former province lived a viscount of Ventadour, Eble, who during the second part of William of Poitiers's life seems to have been brought into relation with him, and according to a contemporary historian, Geffrei, prior of Vigéois, *erat valde graciosus in cantilenis*. We possess none of his compositions; but under his influence Bernart of Ventadour was trained to poetry, who, though only the son of one of the serving-men of the castle, managed to gain the love of the lady of Ventadour, and, when on the discovery of their amour he had to depart elsewhere, received a gracious welcome from Eleanor of Guienne, consort (from 1152) of Henry II. of England. Of Bernart's compositions we possess about fifty songs of elegant simplicity, some of which may be taken as the most perfect specimens of love poetry Provençal literature has ever produced. Bernart must therefore have been in repute before the middle of the 12th century; and his poetic career extended well on towards its close. At the same period, or probably a little earlier, flourished Cercamon, a poet certainly inferior to Bernart, to judge by the few pieces he has left us, but nevertheless of genuine importance among the troubadours both because of his early date and because definite information regarding him has been preserved. He was a Gascon, and composed, says his old biographer, "pastorals" according to the ancient custom (*pastorelas a la usansa antiga*). This is the record of the appearance in the south of France of a poetic form which ultimately acquired large development. The period at which Cercamon lived is determined by a piece where he alludes very clearly to the approaching marriage of the king of France, Louis VII., with Eleanor of Guienne (1137). Among the earliest troubadours may also be reckoned Marcabrun, a pupil of Cercamon's, from whose pen we have about forty pieces, those with dates ranging from 1135 to 1148 or thereabout. This poet has great originality of thought and style. His songs, several of which are historical, are free from the commonplaces of their class, and contain curious strictures on the corruptions of the time.

We cannot here do more than enumerate the leading troubadours and briefly indicate in what conditions their poetry was developed and through what circumstances it fell into decay and finally disappeared:—Peter of Auvergne (Peire d'Alvernha), who in certain respects must be classed with Marcabrun; Arnaut Daniel, remarkable for his complicated versification, the inventor of the *sestina*, a poetic form for which Dante and Petrarch express an admiration difficult for us to understand; Arnaut de Mareuil (Arnaut de Maroill), who, while less famous than Arnaut Daniel, certainly surpasses him in elegant simplicity of form and delicacy of sentiment; Bertran de Born, now the most generally known of all the troubadours on account of the part he played both by his sword and his *sirventes* in the struggle between Henry II. of England and his rebel sons; Peire Vidal of Toulouse, a poet of varied inspiration, who grew rich with gifts bestowed on him by the greatest nobles of his time; Guiraut de Borneil, *lo maestre dels trobadors*, and at any rate master in the art of the so-called "close" style (*trobar clus*), though he has also left us poems of charming simplicity; Gaucelm Faidit, from whom we have a touching lament (*planh*) on the death of Richard Cœur de Lion; Folquet of Marseilles, the most powerful thinker among the poets of the south, who from being a troubadour became first a monk, then an abbot, and finally bishop of Toulouse.

It is not without interest to discover from what class of society the troubadours came. Many of them, there is no doubt, had a very humble origin. Bernart of Ventadour's

father was a servant, Peire Vidal's a maker of furred garments, Perdigon's a fisher. Others belonged to the bourgeoisie; Peire d'Alvernha, for example, Peire Raimon of Toulouse, Elias Fonsalada. More rarely we see traders' sons becoming troubadours; this was the case with Folquet of Marseilles and Aimeric de Pegulhan. A great many were clerics, or at least studied for the church,—for instance, Arnaut of Mareuil, Hugh of Saint Circq (Uc de Saint Circ), Aimeric de Belenoi, Hugh Brunet, Peire Cardinal; some had even taken orders—the monk of Montaudon, the monk Gaubert of Puicibot. Ecclesiastical authority did not always tolerate this breach of discipline. Gui d'Uissel, canon and troubadour, was obliged by the injunction of the pontifical legate to give up his song-making. One point is particularly striking—the number of nobles (usually poor knights whose incomes were insufficient to support their rank) who became troubadours, or even, by a greater descent, jongleurs—Raimon de Miraval, Pons de Capdoill, Guillem Azemar, Cadenet, Peirol, Raimbaut de Vaqueiras, and many more. There is no doubt they betook themselves to poetry not merely for their own pleasure, but for the sake of the gifts to be obtained from the nobles whose courts they frequented. A very different position was occupied by such important persons as William of Poitiers, Raimbaut of Orange, the viscount of Saint Antonin, William of Berga, and Blacatz, who made poetry for their own amusement, but contributed not a little, by thus becoming troubadours, to raise the profession.

The profession itself was entirely dependent on the existence and prosperity of the feudal courts. The troubadours could hardly expect to obtain a livelihood from any other quarter than the generosity of the great. It will consequently be well to mention the more important at least of those princes who are known to have been patrons and some of them practisers of the poetic art. They are arranged approximately in geographical order, and after each are inserted the names of those troubadours with whom they were connected.

*France*.—ELEANOR OF GUIENNE, Bernart of Ventadour (Ventadorn); HENRY CURTMANTLE, son of Henry II. of England, Bertran de Born; RICHARD CŒUR DE LION, Arnaut Daniel, Peire Vidal, Folquet of Marseilles, Gaucelm Faidit; ERMENGARDE OF NARBONNE (1143–1192), Bernart of Ventadour, Peire Rogier, Peire d'Alvernha; RAIMON V., count of Toulouse (1143–1194), Bernart of Ventadour, Peire Rogier, Peire Raimon, Hugh Brunet, Peire Vidal, Folquet of Marseilles, Bernart of Durfort; RAIMON VI., count of Toulouse (1194–1222), Raimon de Miraval, Aimeric de Pegulhan, Aimeric de Belenoi, Ademar lo Negre; ALPHONSE II., count of Provence (1185–1209), Elias de Barjols; RAIMON BERENGIER IV., count of Provence (1209–1245), Sordel; BARRAL, viscount of Marseilles (died c. 1192), Peire Vidal, Folquet of Marseilles; WILLIAM VIII., lord of Montpellier (1172–1204), Peire Raimon, Arnaut de Mareuil, Folquet of Marseilles, Guiraut de Calanson, Aimeric de Sarlat; ROBERT, dauphin of Auvergne (1169–1234), Peirol, Perdigon, Pierre de Maensac, Gaucelm Faidit; GUILLAUME DU BAUS, prince of Orange (1182–1218), Raimbaut de Vaqueiras, Perdigon; SAVANIC DE MAULHON (1200–1230), Gaucelm de Puicibot, Hugh of Saint Circq; BLACATZ, a Provençal noble (1200?–1236), Cadenet, Jean d'Aubusson, Sordel, Guillem Figuera; HENRY I., count of Rodez (1208–1222?), Hugh of Saint Circq; perhaps HUGO IV., count of Rodez (1222?–1274), and HENRY II., count of Rodez (1274–1302), Guiraut Riquier, Folquet de Lunel, Serveri de Girone, Bertran Cartonel; NUNYO SANCHEZ, count of Roussillon (died in 1241), Aimeric de Belenoi; BERNARD IV., count of Astarae (1249–1291), Guiraut Riquier, Amanieu de Sescas.

*Spain*.—ALPHONSE II., king of Aragon (1162–1196), Peire Rogier, Peire Raimon, Peire Vidal, Cadenet, Guiraut de Cabreira, Elias de Barjols, the monk of Montaudon, Hugh Brunet; PETER II., king of Aragon (1196–1213), Raimon de Miraval, Aimeric de Pegulhan, Perdigon, Ademar lo Negre, Hugh of Saint Circq; JAMES I., king of Aragon (1213–1276), Peire Cardinal, Bernart Sicart de Marceols, Guiraut Riquier, At de Mons; PETER III., king of Aragon (1276–1285), Paulet of Marseilles, Guiraut Riquier, Serveri de Girone; ALPHONSO IX., king of Leon (1188–1214), Peire Rogier, Guiraut de Borneil, Aimeric de Pegulhan, Hugh of Saint Circq; ALPHONSO X., king of Castile (1252–1284), Bertran de Lamanou.

Bonifaci Calvo, Guiraut Riquier, Folquet de Lunel, Arnaut Plages, Bertran Carbonel.

*Italy.*—**BONIFACE II.**, marquis of Montferrat (1192–1207), Peire Vidal, Raimbaut de Vaqueiras, Elias Cairel, Gaucelm Faidit (?); **FREDERICK II.**, emperor (1215–1250), Jean d'Anbusson, Aimeric de Pegulhan, Guillem Figueira; **Azzo VI.**, marquis of Este (1196–1212), Aimeric de Pegulhan, Rambertin de Buvalle; **Azzo VIII.**, marquis of Este (1215–1264), Aimeric de Pegulhan.

The first thing that strikes one in this list is that, while the troubadours find protectors in Spain and Italy, they do not seem to have been welcomed in French-speaking countries. This, however, must not be taken too absolutely. Provençal poetry was appreciated in the north of France. There is reason to believe that when Constance, daughter of one of the counts of Arles, was married in 998 to Robert, king of France, she brought along with her Provençal jongleurs. Poems by troubadours are quoted in the French romances of the beginning of the 13th century; some of them are transcribed in the old collections of French songs, and the preacher Robert de Sorbon informs us in a curious passage that one day a jongleur sang a poem by Folquet of Marseilles at the court of the king of France. But in any case it is easy to understand that, the countries of the *langue d'oui* having a full developed literature of their own suited to the taste of the people, the troubadours generally preferred to go to regions where they had less to fear in the way of competition.

The decline and fall of troubadour poetry was mainly due to political causes. When about the beginning of the 13th century the Albigensian war had ruined a large number of the nobles and reduced to lasting poverty a part of the south of France, the profession of troubadour ceased to be lucrative. It was then that many of those poets went to spend their last days in the north of Spain and Italy, where Provençal poetry had for more than one generation been highly esteemed. Following their example, other poets who were not natives of the south of France began to compose in Provençal, and this fashion continued till, about the middle of the 13th century, they gradually abandoned the foreign tongue in northern Italy, and somewhat later in Catalonia, and took to singing the same airs in the local dialects. About the same time in the Provençal region the flame of poetry had died out save in a few places—Narbonne, Rodez, Foix, and Astarac—where it kept burning feebly for a little longer. In the 14th century composition in the language of the country was still practised; but the productions of this period are mainly works for instruction and edification, translations from Latin or sometimes even from French, with an occasional romance. As for the poetry of the troubadours, it was dead for ever.

*Form.*—Originally the poems of the troubadours were intended to be sung. The poet usually composed the music as well as the words; and in several cases he owed his fame more to his musical than to his literary ability. Two manuscripts preserve specimens of the music of the troubadours; but, as the subject has not as yet been investigated, we are still ignorant of one of the elements of their success. The following are the principal poetic forms which they employed. The oldest and most usual generic term is *vers*, by which is understood any composition intended to be sung, no matter what the subject. At the close of the 12th century it became customary to call all verse treating of love *canço*,—the name *vers* being then more generally reserved for poems on other themes. The *sirventes* differs from the *vers* and the *canço* only by its subject, being for the most part devoted to moral and political topics. Peire Cardinal is celebrated for the *sirventes* he composed against the clergy of his time. The political poems of Bertran de Born are *sirventes*. There is reason to believe that originally this word meant simply a poem composed by a *sirvent* (Lat. *serviens*) or man-at-arms. The *sirventes* is very frequently composed in the form, sometimes even with the rhymes, of a popular song, so that it might be sung to the same air. The *tenson* is a debate between two interlocutors, each of whom has a stanza in turn. The *partimen* (Fr. *jeu parti*) is also a poetic debate, but it differs from the *tenson* in so far that the range of debate is limited. In the first stanza one of the partners proposes two alternatives; the other partner chooses one of them and defends

it, and the opposite side remains to be defended by the original proponent. Often in a final couplet a judge or arbiter is appointed to decide between the parties. This poetic game is mentioned by William, count of Poitiers, at the end of the 11th century. The *pastorela*, afterwards *pastorela*, is in general an account of the love adventures of a knight with a shepherdess. All these classes have one form capable of endless variations, five or more stanzas and one or two envois. The *dansa* and *balada*, intended to mark the time in dancing, are pieces with a refrain. The *alba*, which has also a refrain, is, as the name indicates, a waking or morning song at the dawning of the day. All these classes are in stanzas. The *descort* is not thus divided, and consequently it must be set to music right through. Its name is derived from the fact that, its component parts not being equal, there is a kind of "discord" between them. It is generally reserved for themes of love. Other kinds of lyric poems, sometimes with nothing new about them except the name, were developed in the south of France; but those here mentioned are the more important.

*Narrative Poetry.*—Although the strictly lyric poetry of the troubadours forms the most original part of Provençal literature, it must not be supposed that the remainder is of trifling importance. Narrative poetry, especially, received in the south of France a great development, and, thanks to recent discoveries, a considerable body of it has already become known. Several classes must be distinguished:—the *chanson de geste* legendary or historic, the romance of adventure, and the novel. Northern France remains emphatically the native country of the *chanson de geste*; but, although in the south different social conditions, a more delicate taste, and a higher state of civilization prevented a similar profusion of tales of war and heroic deeds, Provençal literature has some highly important specimens of this class. The first place belongs to *Girart de Roussillon*, a poem of ten thousand verses, which relates the struggles of Charles Martel with his powerful vassal the Burgundian Gerard of Roussillon. It is a literary production of rare excellence and of exceptional interest for the history of civilization in the 11th and 12th centuries. *Gerard of Roussillon* belongs only within certain limits to the literature of southern France. The recension which we possess appears to have been made on the borders of Limousin and Poitou; but it is clearly no more than a recast of an older poem no longer extant, probably either of French or at least Burgundian origin. To Limousin also seems to belong the poem of *Aigars and Maurin* (12th century), of which we have unfortunately only a fragment so short that the subject cannot be clearly made out. Of less heroic character is the poem of *Daurel and Belon* (end of the 12th or beginning of the 13th century), connected with the cycle of Charlemagne, but by the romantic character of the events more like a regular romance of adventure. We cannot, however, form a complete judgment in regard to it, as the only MS. in which it has been preserved is defective at the close, and that to an amount there is no means of ascertaining. Midway between legend and history may be classified the Provençal *Chanson of Antioch*, a fragment of which, 700 verses in extent, has been recently recovered in Madrid and published in *Archives de l'Orient Latin*, vol. ii. To history proper belongs the *chanson* of the crusade against the Albigensians, which, in its present state, is composed of two poems one tacked to the other: the first, containing the events from the beginning of the crusade till 1213, is the work of a certain William of Tudela, a moderate supporter of the crusaders; the second, from 1213 to 1218, is by a vehement opponent of the enterprise. The language and style of the two parts are no less different than the opinions. Finally, about 1280 a native of Toulouse named Guillaume Anelier composed, in the *chanson de geste* form, a poem on the war carried on in Navarre by the French in 1276 and 1277. It is an historical work of little literary merit. All these poems are, as *chansons de geste* ought to be, in stanzas of indefinite length, with a single rhyme. *Gerard of Roussillon*, *Aigars and Maurin*, and *Daurel and Belon* are in verses of ten, the others in verses of twelve syllables. The peculiarity of the versification in *Gerard* is that the pause in the line occurs after the sixth syllable, and not, as is usual, after the fourth. Like the *chanson de geste*, the romance of adventure is but slightly represented in the south; but it is to be borne in mind that many works of this class must have perished, as is rendered evident by the mere fact that, with few exceptions, the narrative poems which have come down to us are each known by a single manuscript only. We possess but three Provençal romances of adventure:—*Jaufré* (composed in the middle of the 13th century and dedicated to a king of Aragon, possibly James I.), *Blandin of Cornwall*, and *Guillem de la Barra*. The first two are connected with the Arthurian cycle: *Jaufré* is an elegant and ingenious work; *Blandin of Cornwall* the dullest and most insipid one can well imagine. The romance of *Guillem de la Barra* tells an unlikely story also found in Boccaccio's *Decameron* (2d Day, viii.). It is rather a poor poem; but as a contribution to literary history it has the advantage of being dated. It was completed in 1318, and is dedicated to a noble of Languedoc called Sicart de Montaut. Connected with the romance of adventure is the novel (in Provençal *novas*, always in the plural), which

is originally an account of an event "newly" happened. The novel must have been at first in the south what, as we see by the *Decameron*, it was in Italy, a society pastime,—the wits in turn relating anecdotes, true or imaginary, which they think likely to amuse their auditors. But before long this kind of production was treated in verse, the form adopted being that of the romances of adventure—octosyllabic verses rhyming in pairs. Some of those novels which have come down to us may be ranked with the most graceful works in Provençal literature; two are from the pen of the Catalan author Raimon Vidal de Besalú. One, the *Castia-gilos* (the Chastisement of the Jealous Man), is a treatment, not easily matched for elegance, of a frequently-handled theme—the story of the husband who, in order to entrap his wife, takes the disguise of the lover whom she is expecting and receives with satisfaction blows intended, as he thinks, for him whose part he is playing; the other, *The Judgment of Love*, is the recital of a question of the law of love, departing considerably from the subjects usually treated in the novels. Mention may also be made of the novel of *The Parrot* by Arnaut de Carcassonne, in which the principal character is a parrot of great eloquence and ability, who succeeds marvellously in securing the success of the amorous enterprises of his master. Novels came to be extended to the proportions of a long romance. *Flamenca*, which belongs to the novel type, has still over eight thousand verses, though the only MS. of it has lost some leaves both at the beginning and at the end. This poem, composed in all probability in 1234, is the story of a lady who by very ingenious devices, not unlike those employed in the *Miles Gloriosus* of Plautus, succeeds in eluding the vigilance of her jealous husband. No analysis can be given here of a work the action of which is so highly complicated; suffice it to remark that there is no book in mediæval literature which betokens so much quickness of intellect and is so instructive in regard to the manners and usages of polite society in the 13th century. We know that novels were in great favour in the south of France, although the specimens preserved are not very numerous. Statements made by Francesc de Barberino (early part of 14th century), and recently brought to light, give us a glimpse of several works of this class which have been lost. From the south of France the novel spread into Catalonia, where we find in the 14th century a number of novels in verse very similar to the Provençal ones, and into Italy, where in general the prose form has been adopted.

**Didactic and Religious Poetry.**—Compositions intended for instruction, correction, and edification were very numerous in the south of France as well as elsewhere, and, in spite of the enormous losses sustained by Provençal literature, much of this kind still remains. But it is seldom that such works have much originality or literary value. Originality was naturally absent, as the aim of the writers was mainly to bring the teachings contained in Latin works within the reach of lay hearers or readers. Literary value was not of course excluded by the lack of originality, but by an unfortunate chance the greater part of those who sought to instruct or edify, and attempted to substitute moral works for secular productions in favour with the people, were persons of limited ability. It is needless to enumerate all the lives of saints, all the treatises of popular theology and morals, all the books of devotion, all the pious canticles, composed in Provençal during the Middle Ages. Enough to recall the Boetius poem (unfortunately a mere fragment) already mentioned as one of the oldest documents of the language, and really a remarkable work. From the multitude of saints' lives we may single out that of St Honorat of Lerins by Raimon Feraud (about 1300), which is distinguished by variety and elegance of versification, but is almost entirely a translation from Latin. Among poems strictly didactic one stands out by reason of its great extent (nearly thirty-five thousand verses) and the somewhat original conception of its scheme—the *Breviari d'amor*, a vast encyclopædia, on a theological basis, composed by the Minorite friar Matfre Ermengaut of Béziers between 1288 and 1300 or thereabout.

**Drama.**—Twenty years ago it might have been questioned whether dramatic representation was known in the south of France, but within that time several short dramatic pieces have been published or described; and a considerable number of actual theatrical representations have been found mentioned in the local records. Everything of this kind that we know of belongs to the religious drama, the oldest form in every mediæval literature. The period at which a purely secular theatre takes its rise in most quarters is the 15th century; and by that time there was hardly any Provençal literature left. We possess in Provençal mysteries of Saint Agnes, of the Passion, of the Marriage of the Virgin, all belonging to the close of the 13th century or the first half of the 14th. In the 16th century there is a fragment of a mystery of St James. Provence properly so-called, especially the eastern portion of it, seems to have been particularly fond of representations of this sort, to judge by the entries in the local records. At the close of the 15th and the beginning of the 16th century many mysteries were played in that part of Dauphiné which corresponds to the present department of Hautes-Alpes. Five mysteries of this district, composed and played somewhere about 1500 (the mysteries of St Eustace, of

St Andrew, of St Pons, of Sts Peter and Paul, and of St Anthony of Vienne), have come down to us, and are now (1886) being edited. The influence of the contemporary French sacred drama may to some extent be traced in them.

**Prose.**—Prose composition in the south of France belongs to a comparatively late stage of literary development; and the same remark applies to the other Romance countries, particularly to northern France, where prose hardly comes into fashion till the 13th century, the prose of the preceding century being little else than translations of the books of the Bible (especially the Psalter).

As early as the 12th century we find in the south sermons, whose importance is more linguistic than literary. To the 13th century belong certain lives of the troubadours intended to be prefixed to, and to explain, their poems. They were written before 1250, when the first anthologies of troubadour poetry were compiled; and some of them are the work of the troubadour Hugh of Saint Cirq. To the same period must be assigned *Las lincos de trobar* of the troubadour Raimon Vidal de Besalú (an elegant little treatise touching on various points of grammar and the poetic art), and also the *Donatz Proensals* of Hugh Faidit, a writer otherwise unknown, who drew up his purely grammatical work at the request of two natives of northern Italy. Of about the same date are two translations of the New Testament, one of which, preserved in MS. at Lyons, seems to have been made for Albigenians. A remarkable work, both in style and thought, is the *Life of St Donceline*, who lived at the close of the 13th century near Marseilles, and founded an order of Beguines. In the 14th century compositions in prose grew more numerous. Some rare local chronicles may be mentioned, the most interesting being that of Mascaró, which contains the annals of the town of Béziers from 1338 to 1390. Theological treatises and pious legends translated from Latin and French also increase in number. The leading prose work of this period is the treatise on grammar, poetry, and rhetoric known by the name of *Leys d'Amors*. It was composed in Toulouse, shortly before 1350, by a group of scholars, and was intended to fix the rules of the language with a view to the promotion of a poetical renaissance. For this purpose an academy was founded which awarded prizes in the shape of flowers to the best compositions in verse. We still possess the collection of the pieces crowned by this academy during the 14th century, and a large part of the 15th (*Flors del gay saber*). Unfortunately they are rather academic than poetic. The *Leys d'Amors*, which was to be the starting point and rule of the new poetry, is the best production of this abortive renaissance. The decay of Provençal literature arrived too soon to allow of a full development of prose. The 14th and 15th centuries were in no respect a prosperous period for literature in the south of France. In the 15th century people began to write French both in verse and prose; and from that time Provençal literature became a thing of the past.

**Bibliography.**—Fauriel, *Histoire de la poésie provençale* (Paris, 1816, 3 vols. 8vo), is quite antiquated. Not only are three-fourths of the works in Provençal poetry ignored, but the very idea of the book is vitiated by the author's system (now abandoned), based on the supposition that in the south of France there was an immense epic literature. The articles on the troubadours in the *Histoire littéraire de la France*, by Ginguené, L. David, &c., must be consulted with extreme caution. F. Diez's *Die Poesie der Troubadours* (Zwickau, 1827, 8vo); new ed. by Bartsch, 1853; and his *Leben und Werke der Troubadours* (Zwickau, 1829, 8vo; new ed. by Bartsch, 1852) are of great excellence for the time at which they appeared. For the history of Provençal literature in Spain, see Mila y Fontanals, *De los trovadores en España* (Barcelona, 1861, 8vo); for Italy, Cavedoni, *Ricerche storiche intorno ai trovatori provenzali* (Modena, 1844, 8vo); A. Thomas, *Francesco Barberino et la littérature provençale en Italie* (Paris, 1854, 8vo); O. Schultz, "Die Lebensverhältnisse der italienischen Troubadours," in *Zeits. für romanische Philologie* (1853). For the bibliography consult especially Bartsch, *Grundriss zur Geschichte der provenzalischen Literatur* (Elberfeld, 1872, 8vo). For texts the reader may be referred to Raynouard, *Choix de poésies originales des troubadours* (1816-21, 6 vols. 8vo), and *Lexique roman, ou dict. de la langue des troubadours*, of which vol. I. (1838) is entirely taken up with texts; and Rochemonteix, *Parnasse occitanien* (Toulouse, 1819, 8vo). All the pieces published by Raynouard and Rochemonteix have been reprinted without amendment by Mühl, *Die Werke der Troubadours in provenz. Sprache* (Berlin, 8vo, vol. I. 1846, II. 1855-64, III. 1880, IV. containing an edition of the troubadour Guiraut Riquier, 1884). The same editor's *Gedichte der Troubadours* (Berlin, 1856-73) is a collection conspicuous for its want of order and of accuracy (see *Romania*, III. 303). Among editions of individual troubadours may be mentioned—*Pierre Vidal's Lieder*, by Karl Bartsch (Paris, 1871, 8vo); *Der Troubadour Jaufré Rudel, sein Leben und seine Werke*, by A. Stimming (Kiel, 1873, 8vo); *Bertran de Born, sein Leben und seine Werke*, by A. Stimming (Halle, 1878, 8vo); *Guilhem Figueira, ein provenzalischer Troubadour*, by E. Levy (Bonn, 1880, 8vo); *Das Leben und die Lieder des del trovatore Arnaldo Daniello*, by Carl Appel (Bonn, 1892, 8vo); *La vita e le opere del trovatore Arnaldo Daniello*, by U. A. Canello (Halle, 1883, 8vo). Among editions of Provençal works of a miscellaneous kind are—Bartsch, *Denkmäler der provenzalischen Literatur* (Stuttgart, 1856, 8vo); H. Snell, *Denkmäler der provenz. Literatur und Sprache* (Halle, 1883-85, 2 vols. 8vo); Fr. Arnal, *Sermons du XII siècle en vieux provençal* (Hollbronn, 1884, 12mo); Paul Meyer, *La Chanson de la Croisade contre les Albigeois*, (Paris, 1876-79, 2 vols. 8vo); Id., *Dauriel et Deion, Chanson de geste provençale* (Paris, 1880, 8vo); Id., *Le Roman de matiken, le Donatz proensals und las Razos de trobar* (Münch., 1878, 8vo); Bartsch, *Sancta Agnes, provenz. geistliches Schauspiel* (Berlin, 1867, 8vo); *Le Breviari d'amor de Matfre Ermengaut*, published by the Archaeological Society of Béziers (Béziers, 1862-80, 2 vols. 8vo); A. L. Sardon, *La Vida de Sant Honorat, légende en vers provençaux par Raymond Feraud* (Nice 1876, 8vo). Documents and dissertations on various points of Provençal literature will be found in almost all the volumes of *Romania* (Paris, in progress since 1872, 8vo), and the *Revue des Langues romanes* (Montpellier, in progress since 1870, 8vo). See also the other journals devoted in Germany and Italy to the Romance languages, *passim*. (P. M.)

PROVENCE (*Provincia*), a province of France lying to the extreme south-east on the shores of the Mediterranean, bounded on the W. by Languedoc, on the N. by Venaissin and Dauphiné, and on the E. by Italy. It now forms the departments of Bouches-du-Rhône, Var, and Basses-Alpes, with portions of Vaucluse and Alpes Maritimes. It was divided into Upper Provence, containing the four seneschalates of Forcalquier, Castellane, Sisteron Digne, and the Valley of Barcelonnette; and Lower Provence, containing the eight seneschalates of Aix, Arles, Brignoles, Grasse, Marseilles, Draguignan, Hyères, and Toulon. In ancient as in modern times the most important city was Marseilles (*Massilia*), a chief seat of trade for the Greek merchants of the Mediterranean, who extended their power along the coast and founded Agde, Antibes, Grasse, and Nice. They afterwards called in the aid of the Romans (125 B.C.) against the Ligurian inhabitants of the surrounding country, and the new-comers soon made themselves masters of the territory which later formed the provinces of Languedoc, Dauphiné, and Provence. The new province, of which the capital was *Aquæ Sextiæ* (Aix), was called *Provincia Gallica* until the total conquest of Gaul, when the name of the district was changed to *Gallia Narbonensis*. In the 4th century of the Christian era, when the greater part of Languedoc, or *Narbonensis Prima*, had become subject to the Visigoths, and the Burgundians had spread to the Viennois, *Provincia* came to be applied only to the country lying between the Rhone, the Durance, and the Alps which was still held by the Romans. But they could not withstand for long the advancing tide of barbarian power. Although the Visigothic king Theodoric I. was defeated by Aëtius before Arles in 425 A.D., and their united armies in turn defeated Attila in 451, yet Theodoric II. imposed the emperor Avitus on the Romans, and Euric by the capture of Arles (480) made the Visigoths masters of Provence. Their defeat at the battle of Bouglé in 507 by Clovis and Gundibald, king of the Burgundians, placed Provence at the mercy of the latter, who ceded it in 511 to Theodoric, king of the Ostrogoths, as guardian of the Visigothic king. The powers so gained were, however, resigned by his successor Witiges in 536 to Theodebert, king of the Franks, who had previously overthrown the Burgundian kingdom. On the death of Clotaire I. (561) Provence was divided between his sons Sigebert, king of Austrasia, and Gontran, king of Burgundy, Marseilles falling to the former and Arles to the latter. When Gontran died in 593 the province was united under his nephew Childebert, only to be divided again by his sons and reunited under Clotaire II. (613), until the sons of Dagobert, Sigebert II. and Clovis II. (633) parted it between them. In 719 the Saracens crossed the Pyrenees and made themselves masters of almost all Septimania, or Languedoc, and in 739 they joined with Maurontis, a Byzantine governor of Marseilles, in his attempt to drive out the Franks. Fortunately for Europe their forces were completely defeated by Charles Martel, who again united Provence to the Frankish kingdom. On the division of the Carolingian empire in 843 Provence fell to Lothair, who left it with the title of king to his son Charles (855), at whose death without issue in 863 it was seized by Charles the Bald. In 879 his brother-in-law Boson, a son-in-law of the emperor Louis II., and governor of Vienne, was elected king by the synod of Mantale, when his united provinces became known as Cisjuran Burgundy. His son, Louis the Blind, obtained the crown of Italy (900), but was deposed by Hugo, who, in his turn obtaining the Italian kingdom, ceded Provence in 932 to Rudolph II., king of Transjuran Burgundy. The two Burgundies thus united received the name of the Kingdom of Arles, which lasted in a phantom form until

1032, but Provence was always governed by princes whose powers gradually increased, until the county was changed from a beneficiary to an hereditary fief. The line of beneficiary counts begins with Boson I. (926), who was reinvested by Rudolph II. in 934. He was succeeded by Boson II. (948), whose son William I. (968) signalized his reign by driving out from the stronghold of Fraxinet the Moorish pirates who had seized it in 889, and thence ravaged the neighbouring country. His brother Rothbold, who held the fief until 1008, was followed by his nephew William II., and, as the union of the kingdom of Arles with the German empire was by this time almost nominal, the counts of Provence claimed independence, and William's sons, Geoffrey-Bertrand I. and William III., divided the county in 1018 as an allodial fief. William III. died in 1053 and Geoffrey-Bertrand handed over to his nephews the northern part, or the county of Forcalquier, he himself retaining the main province to which his son Bertrand II. succeeded in 1063. At his death without issue in 1093 the county was ruled by his mother Étienne, who was followed (1100) by her daughter Gerberge, wife of Gilbert, viscount of Milhaud and Gévaudan. Their daughter Douce was married to Raymond-Bérenger, count of Barcelona, of the house of Aragon, and Provence passed to him in 1112. But his succession was not undisputed. Raymond de S. Gilles, count of Toulouse and Venaissin, a great-grandson of Rothbold, had about 1085 laid claim to the county of Forcalquier, and his pretensions were probably partly admitted. The excitement of the crusades put a stop to further action, and in 1096, accompanied by Count Gilbert, he led the Provençal contingent, which was, however, more distinguished for foraging than fighting. On his death in 1105 his claims were revived by his son Alfonse Jourdain, who succeeded in obtaining from Raymond-Bérenger an extension of the county of Venaissin. Raymond-Bérenger I. died in 1130, and was succeeded by his son Bérenger-Raymond, whose rights were disputed by Raymond de Baux, husband of his mother's sister Étienne. In the war which ensued the count was killed before Melgueil, leaving a young son, Raymond-Bérenger II. (1144), to the guardianship of his uncle, Raymond-Bérenger of Aragon. The claims of Raymond de Baux were renewed by his son Hugo, on whose defeat in 1162 the emperor Frederick I. gave his niece Richilda in marriage to the young count, and invested him with the fiefs of Provence and Forcalquier. His only daughter Douce had been betrothed to the count of Toulouse, who accordingly on the death of Raymond-Bérenger II. (1166) claimed the county, but was defeated by Alphonso I. of Aragon, who invested his brother Raymond-Bérenger III., on whose death in 1181 the fief reverted to Alphonso I. to pass to his son Alphonso II. (1196). This prince died in 1209, and was succeeded by his son Raymond-Bérenger IV., who, seeing that the great cities were nests of intrigue for rivals to the throne, set himself to destroy their independence. Through all changes of rulers the cities had kept their internal freedom and old Roman self-government. The election of the governing body had always remained in the hands of the citizens, but the office of chief magistrate, after ceasing to be filled by a nominee of the Byzantine emperor, had become vested either in certain families or in the bishops. In the 12th century measures of reform were imitated from the Italian republics, the chief characteristic of which was the election for life of a stranger as chief magistrate or *podestà*. The power of the *podestà* was too great to be broken at once, and, though the Albigenses in Avignon capitulated in 1226, and Nice, Grasse, Toulon, and Marseilles afterwards submitted to Raymond-Bérenger IV., it was left to his son-in-law, CHARLES OF ANJOU (see

vol. v. pp. 422-23), to replace the podestàs by governors of his own nomination (1246). Charles died in 1285, leaving the states of Anjou, Provence, and Naples to his son Charles II., under whose rule peace and prosperity to some extent revived. But the efforts of his son Robert (1309) in the cause of the Guelphs called for increased taxation, and he left a troubled heritage to his granddaughter Joan of Naples (1343). To avenge the murder of his brother Andrew, the husband of Joan, at whose instigation the crime had been committed, Louis of Hungary marched into Italy (1347), and made himself master of the kingdom of Naples. Joan fled to Provence, and by timely concessions to her people secured their favour in her efforts to regain the Neapolitan crown. But money was needed; so Avignon, where the popes had resided since 1305, was sold to Pope Clement VI., and Joan won back Naples. An important part in the affair was played by the Provençal estates, which consisted of the three houses of clergy, nobility, and commons, and were supreme in all financial matters, however absolute the counts might be in other branches of government. This power of the purse was jealously guarded, and the subsidies granted to the prince were never considered as other than *dons gratuits*, the name by which they were called even after the union with France, when they became an annual tribute. Owing to the right of *répartition* to definite objects of the sums raised by taxation, the Provençaux were not on the whole badly governed, for, though the estates had only the right of petition for legislation, yet when the need arose they could very effectually speak with the voice of the whole people. The representation of the bulk of the nation in the tiers-état was particularly good, for the deputies, who were paid, were returned not only by the twenty-five country electorates, or vigueries, but from thirty-seven communes as well. The English constitution may therefore be indebted to Provence for the important step which was taken by the younger Simon de Montfort in first summoning the representatives of cities and boroughs to the parliament of 1265. The earliest recorded session of the estates was in 1146, and the meetings continued at intervals until 1639, when they ceased until 1787. The sessions not being annual, the powers of the estates in ordinary matters were delegated to a general assembly, composed of the archbishop of Aix, the procureurs joints, who were representatives of each of the estates of the clergy and the nobility, and the whole of the tiers-état. This assembly gradually superseded the estates until in 1639 it replaced them altogether. To meet sudden emergencies there was a "great council," which consisted of the archbishop and three consuls of Aix as procureurs du pays, and the procureurs joints of the three estates, under the presidency of the grand seneschal. This officer was the representative of the counts in judicial affairs, and during their absence from the country in military matters also. His powers were not only administrative, but to a great extent legislative, and they were therefore fated either to increase at the expense of the sovereign or to be cut down by a firm ruler. Joan chose the latter course, and deprived the grand seneschal of his powers over the state domains, and his right to remove judges and pardon capital crimes. And she not only reduced his power but appointed an Italian to the office, upon which the nation rose in revolt, and Louis of Anjou, seizing the opportunity to press his claims to the throne, led an army into Provence in 1368. The pretensions of Louis were met by Joan's offer to adopt him as her heir, and on her death in 1382 he succeeded to the county. The reign of Louis I. was passed in the unsuccessful pursuit of his claims to the kingdom of Naples, and his son Louis II. (1384) and grandson Louis III. (1417) con-

tinued the same unprofitable contest. René (1434), a brother of Louis III., was not less inclined to give up his rights, which had revived in force from his adoption by Joan II. of Naples, but, though fortune at first smiled on him, he was at last forced to resign his claim in favour of the house of Aragon. The count, or titular king, was an accomplished musician and a lover of literature and the arts; and, the latter part of his reign being on the whole peaceful, he was able to give free play to his inclinations. The artistic fame of his court has lasted to the present day, but it was the interest which he took in his subjects' material welfare, and his administration of wise laws, which caused his people to lament the death of René the Good. He died in 1480, and, leaving only a daughter Margaret, the ill-fated wife of Henry VI. of England, bequeathed the county to his nephew Charles of Maine. Charles III. died in the following year, making Louis XI. of France his heir, and in 1486 Charles VIII. by letters patent reunited the county to the kingdom of France.

The union was confirmed by the estates with the full approval of the people; but the emperor was not inclined to relinquish without a struggle his claims to overlordship, and he found a willing tool in the constable, Charles of Bourbon, who entered Provence at the head of the imperialist army in 1524. His adventure met with failure, and the invasion by the emperor Charles V. himself in 1536 was equally unsuccessful. In 1501 Louis XII., with the view of strengthening his own authority, replaced the "conseil emient," which in the time of the counts had been the highest court of justice, by a "parlement," consisting at first of the grand seneschal, a president, and eleven nominated councillors. The functions of the court were strictly judicial, but before its abolition in 1790 it had often assumed legislative rights, and consequently played a conspicuous part in the civil wars of the 16th and 17th centuries. The principles of the Reformation made what little progress they did in Provence from external rather than internal causes, and the people themselves never took kindly to doctrines which in many ways assumed an extremely bizarre and heretical form. The 13th century had witnessed Simon de Montfort's crusade against the Albigenses of Languedoc, and the ruin which heresy had brought on that province cannot have given the prosperous Provençaux any great love for new doctrines. The Waldenses of the 16th century were therefore chiefly confined to the mountainous districts, but the persecutions ordered by the parlement brought the horrors of civil war on the whole country. The extreme Catholics formed the Holy League against the Protestants, and the two parties were equally at enmity with Henry III., who tried to please both without satisfying either. In time the royalists and Protestants united under the name of *Bigarrats*, but it was not until Henry IV. had come to the throne, and Marseilles, the last stronghold of the League, had submitted, that the worn-out country was again at peace. Richelieu tried to increase the taxation of the people without their consent, but the disorders of the Cascaveaux were the result, and a similar attempt by Mazarin in 1647 led to disturbances in connexion with the Fronde which lasted until 1652. In 1707, during the War of the Spanish Succession, the army of the allies under Prince Eugene invaded the province, and the horrors of war were followed by those of the plague of 1720, when 100,000 persons perished, Marseilles alone losing 50,000 out of a population of 90,000. The dispute between the Jesuits and Jansenists waxed warm about 1726, but the victory of the former only preceded their suppression by Pope Clement XIV. in 1773 in return for the cession of Avignon and the county of Venaissin, which had twice changed hands since their reunion with Provence in 1663. On the re-

convocation of the estates in 1787 the two upper houses refused to bear their share of taxation, and in 1789, in the states-general of the kingdom, Mirabeau with his colleagues renounced the freedom and independence of the province. The division of Provence into departments in 1790 finally obliterated all traces of the ancient constitution, but the people still preserve in the soft tones of their *langue d'oc* an undying reminder of their former independence.

(H. B. B.)

**PROVERBS, Book of.** The title of the book of Proverbs is "The Proverbs of Solomon" (משלי שלמה, *mishlê shelômah*, or more shortly *mishlê*, for which Origen gives the feminine form *mislôth*, Enseb., *H. E.*, vi. 25). The title in the LXX. is a literal rendering of the Hebrew, Προιμίαι Σολομώντος. In early times the book was frequently referred to both among Jews and Christians under the name of "Wisdom" or "The Wisdom that comprises all Virtues" (ἡ πανάρετος σοφία, Clem. Rom., ch. 57). This name, however, was employed somewhat indiscriminately, for not only Proverbs but also Ecclesiastes and the apocryphal books Ecclesiasticus and Wisdom were also designated by it, and sometimes apparently the whole third division of the canon (Lightfoot, *Epp. of S. Clement*, p. 164 sq.).

The book of Proverbs as it now lies before us consists of a number of distinct parts.

1. We have, chap. i. 1-7 (or i. 1-6 as some think), a general heading and preface, giving the title of the book and the purposes to be served by its contents:—"The Proverbs of Solomon, the son of David, king of Israel. To know wisdom and instruction . . . to give subtlety to the simple, to the young man knowledge and discretion . . . to understand a proverb and a figure, the words of the wise and their dark sayings." This is followed by the fundamental maxim of the Wisdom, "The fear of the Lord is the beginning of wisdom." The question to what parts of the book this preface extends is not easy to settle.

2. This general preface is followed by a lengthy passage, i. 8-ix. 18, which consists, not of detached proverbs, though a number of such proverbs are scattered through it, but of connected discourses in praise of wisdom and the benefits which she confers on those who embrace her. The speaker is one of the wise, or a type of them, who addresses his youthful pupil or friend as "my son," though at several points wisdom herself is introduced speaking, displaying her graces, offering herself to men, narrating her history, and magnifying the delights which they who follow her enjoy, as well as painting in dark colours the evils from which she preserves them. Attempts have been made to divide the passage into distinct sections, but without much success. Ewald counts three general divisions, Bertheau seven, Hooykaas eleven, and Delitzsch fifteen. The passage is in the main homogeneous, though containing at more places than one elements which at first sight might appear foreign (e.g., vi. 1 sq.), and on the whole at least is the composition of a single author. Several of its characteristics, such as the style, and particularly the personification of wisdom in chap. viii. and elsewhere, one of the most remarkable and beautiful things in Hebrew literature, indicate that the passage belongs to an advanced stage of the Hebrew wisdom.

3. Then follows the largest section in the book, x. 1-xxii. 16, with a new heading, "The Proverbs of Solomon." This division consists of a number of verses—three hundred and seventy-four, it is said—each of which contains a single proverb or maxim in two lines, the only exception being xix. 7, which has three lines, but this is probably due to one member of a second verse having fallen out. The kind of poetical parallelism most common in these verses is the

antithetic, of the type "A wise son maketh a glad father, but a foolish son is the heaviness of his mother" (x. 1). This type of parallelism prevails almost exclusively in x.-xv., after which other types are more commonly introduced. The proverbs in this collection are of a very miscellaneous character, and are thrown together without any classification or regard to subject, though occasionally a few verses are found to follow one another having reference to a common topic.

4. After this comes a small collection consisting of two parts which have been put together, xxii. 17-xxiv. 22 and xxiv. 23-34. The author of the first collection informs his son or disciple that what he addresses to him is "words of the wise" (xxii. 17); and the second small code is inscribed "These also are by the wise" (xxiv. 23). The proverbs in this collection sometimes make one verse, sometimes two or three, and even occasionally run out to a short proverbial discourse.

5. Then follows an important collection, xxv.-xxix., with the inscription, "These also are proverbs of Solomon, which the men of Hezekiah, king of Judah, copied out" (xxv. 1). The expression "copied out" (LXX. ἐξεγράφαντο), lit. "transferred" or removed from one place to another, implies that the men of Hezekiah made use of written sources in forming their collection. The notice is of great historical interest. Hezekiah, besides being a wise and reforming king, had probably literary tastes; he has the reputation of having been a poet himself (Isa. xxxviii.); and his "men" were no doubt scholars and scribes about his court, who shared in his tastes and pursuits, and under his direction used their opportunities to rescue from oblivion the precious remains of the most ancient wisdom by transferring them from the small collections in which they lay hidden into a single and authorized code (cf. 2 Kings xviii. 37). It may perhaps be considered some corroboration of the genuine historical character of the inscription that the collection begins with a number of proverbs relating to kings. The maxims in this code, particularly in xxv.-xxvii., approach much nearer to what we should imagine the early popular proverb to have been than many of those in the other large collection; they are simple, usually contain a comparison, and have none of the abstractness which characterizes many of the maxims in x.-xxii. This may be regarded as a guarantee of their great antiquity.

6. Two small pieces then follow, evidently related to one another, xxx. and xxxi. 1-9,—the former with the inscription, "The words of Agur, the son of Jakeh," and the other with the heading, "The words of King Lemuel." The inscriptions to these two pieces are very obscure. In the former the A. V. can hardly be correct. More probably by a different division of words we should read—"The words of Agur the son of Jakeh of Massa. The man said, I have wearied myself, O God, I have wearied myself, O God, and am consumed; for I am more brutish than any man," &c. The words are those of one who has striven to comprehend God and found the task above him (Ps. lxxiii. 22). Possibly the above rendering requires a slight correction in the text, already made in the Veneto-Greek version, which renders "Jakeh the Massaite" (Gen. xxiv. 14?). Similarly the heading in xxxi. should probably read—"The words of Lemuel king of Massa, wherewith his mother instructed him." It is uncertain whether the names Agur and Lemuel be real or fictitious.

7. Finally the book is closed by an alphabetical poem, xxxi. 10-31, in praise of the virtuous (that is, the active, capable) woman.

The contents of these several sections are very various and not easy to classify. The proverbialists occupy themselves with life in all its aspects. Sometimes they simply

catch the expression of men good or bad, or photograph their actions and thoughts; more generally they pass a verdict upon them, and exhort or instruct men in regard to them. The proverbs differ from the shrewd or humorous sayings which are so called in profane literature; some of them have a certain flavour of humour, but they are mainly maxims touching practical life on its religious and moral side. Such maxims cannot be regarded as wholly or even in a very large degree the production of an individual mind. A number of them may well be by Solomon, and a greater number may belong to his age; but, though the stream of wisdom began to flow in his day, its beginnings were then comparatively small; as the centuries advanced it gathered volume. In the book which now exists we find gathered together the most precious fruits of the wisdom in Israel during many hundred years, and undoubtedly the later centuries were richer, or at all events fuller, in their contributions than the earlier. The tradition, however, which connects Solomon with the direction of mind known as the wisdom cannot reasonably be set aside. The renown for wisdom which this king enjoyed among his own people, and even, though in a distorted and fantastic form, among the other peoples of the East, must have rested on some real foundation. No doubt reputations grow, and veneration magnifies its hero sometimes in proportion to the indistinctness of its real knowledge of him; and objects seen in the broad light of day are very insignificant compared with the bulk which they assume when seen between us and the light still lingering on the horizon of a day that has gone down. But, making allowance for the exaggerations of later times, we should leave history and tradition altogether unexplained if we disallowed the claim of Solomon to have exercised a creative influence upon the wisdom in Israel. At the same time it is probable that this influence did not lie in the application of new methods, much less in the creation of a new direction of thought. The supposition that Solomon was the inventor of the proverbial distich or *maschal*, particularly of the antithetical distich, or that he was the first to use this in his sententious sayings on men and life, and thus the father of didactic poetry among the Hebrews, is a mere conjecture. The distich was employed long before his day, and sententious maxims regarding life and men long preceded him. Moreover the conjecture is based on the very false assumption that the essence of the wisdom lay in the form of expression rather than in the matter, and that the curt, sharp, antithetical distich was its proper characteristic and belonged to it from the beginning. This assumption, made by Ewald, has been so usually accepted by writers after him that the polished pointed antithesis has been elevated into a criterion of the higher antiquity of those proverbs which possess it. Probably the opposite conclusion would be nearer the truth. The form of these antithetical proverbs betrays art, long use of the literary methods of the wise, and an approach to technicality—things not to be expected in an early age. The early *maschal* was probably simple, containing a figure or comparison, as the name implies; some truth of the life of mankind thrown into an image from nature, without anything artificial or technical. Proverbs like "iron sharpeneth iron," or such fine similes as these—"a trampled fountain and a fouled spring is the righteous man who hath given way before the wicked," "a city that is broken down and hath no wall is the man whose spirit is without control" (xxxv. 26, 28)—are the kind of proverbs which we should look for in this earliest time. Solomon has a place of renown in the wisdom, not because he imposed any mannerism upon it, but because he threw a vigorous mind into it. He probably formed no class: the word "wise" did not, from being an adjective, become a noun in his

days. The nature of his wisdom is best illustrated by the story of the two women with the living and the dead child (1 Kings iii. 16-28). He possessed a keen insight into the operations of human nature; he knew the world and men and life. Most likely also he possessed the power of giving pointed expression to his shrewd and ready judgments; and, as it is said that he spoke of beasts and fishes and trees, he probably had an eye for the analogies between human life and the external world. From his character we should judge that his three thousand proverbs were not all religious; neither were his thousand and one songs all hymns, or some of them would have been preserved to us besides the two more than doubtful poems in the Psalter (Ps. lxxii., cxxvii.). The theme of the wisdom was life, and its aims were practical; and, if the rise of the wisdom be connected with the age of Solomon, that is due to the fact that life in the civil sense began in this age, and its principles could be discovered. Then the tribes were consolidated into one community, the state rose into existence, the channels of commerce were opened, men entered into various and complicated relations with one another, and the principles which rule such relations revealed themselves to the eye that was open to observe them.

It is not quite easy to form definite conceptions of those called the wise in Israel. They were certainly no hereditary caste like the priests; neither had they any distinct call to a vocation like the prophets, although in later times at least they were so well recognized that they could be ranked with these two classes as influential in forming men's opinions and guiding their actions (Jer. xviii. 18). They were probably men who might be named elders, not always because of their age, but because of their superior sagacity; men who, having at heart the welfare of the state and particularly the moral soundness of the citizens, sought to gain the ear of the young and inculcate upon them the principles of right conduct. While the priests were the clergy and lawyers in Israel, and the prophets the statesmen, the wise were the moralists and educationists, whose operations touched the individual in all his relations and duties. Their methods were probably simple to begin with, and natural, without anything strictly characteristic; they were moral "reprovers," or ordinary "counsellors," and possibly at first their ethical maxims were general, touching life as a whole. By and by they surveyed life with a keener scrutiny and subjected it to a sharper analysis, bringing their moral principles to bear on its shades and sides and aspects, and applying these principles with greater inwardness so as to strike not merely at external conduct but at the disposition of the mind. And, finally, under the influence of the universalistic ideas of God and providence suggested to the minds of men in Israel by contact with the great empires of the world and observation of their destinies, when the Jewish state became involved in political movements as wide as the known world, the wise were enabled to gather together the manifold fragments into which they had analysed the moral life of man and the operation of the providence of God, and to perceive that they were all but elements in one great divine system embracing all things, both the world of nature and the destinies of men. To this great scheme, which was but God fulfilling himself in many ways, they gave the name of wisdom in the abstract; it was the counterpart of the divine mind, God's fellow and architect in framing the world. This was the divine wisdom; human wisdom consisted both in intellectual comprehension of it and in moral harmony with it, and the first could be reached only through the second: the fear of the Lord is the beginning of wisdom. Illustrations of the wisdom in its earliest form may be seen in the collection xxxv.-xxix., and in many proverbs in x.-xxii.

(many examples of the period of most subtle analysis in the last-named collection), while the period of synthesis and what comes near to be a science of wisdom is represented in the passage i.-ix. Naturally along with this advance in thought there appeared a corresponding advance in the forms of expression in which the wisdom clothed itself: the wise acquired a method; a particular spirit began to animate their circles; their phraseology showed the impress of a particular mint, and ultimately assumed a form almost technical.

Perhaps some of the things which failed to attract the attention of the wise are more suggestive than those things with which they occupied themselves. Though sacrifice, for example, be once or twice alluded to, no importance is attached to the ritual system; the priest is not once mentioned, and the external exercises of worship appear to have little significance. But, what is more remarkable, the wise man differs as much from the prophet as he does from the lawgiver. All those ideas around which prophecy revolves, such as the idea of the kingdom of God, of a chosen people, of a Messiah or future king of the house of David, and the like, are entirely absent. The distinction between "Israel" and the "nations" has no place. The darling phraseology of the prophets—"Israel," "Jacob," "Zion," "my people," "the latter day"—and the whole terminology of particularism characteristic of prophecy and many even of the Psalms nowhere occurs. The conflict between the worship of Jehovah and that of false gods, with which the pages of prophetic writers are filled, does not receive even a passing reference. Conclusions have been drawn from these peculiarities which, though not unnatural, are scarcely warranted. It has been inferred that the wise were men whose way of thinking placed them outside of their dispensation and in antagonism to the circle of beliefs cherished in Israel and represented by the prophets and other public teachers—in short, that they took up a humanistic or naturalistic position. A position to which the name naturalistic could be given is inconceivable in Israel. There were no doubt men called wise who pursued false directions (Jer. xviii. 18), as there were false prophets; but there is nothing in the Proverbs to indicate any antagonism between their authors and either priest or prophet. On the contrary the passage iii. 9—a solitary one no doubt—"Honour the Lord with thy substance, and with the first fruits of all thine increase," shows their friendliness to the ritual. If they say on the other hand that the sacrifice of the wicked is an abomination to the Lord (xv. 8), and that by mercy and truth iniquity is atoned for (xvi. 6), this is nothing but what the prophets proclaim in a body, and means merely that obedience is better than sacrifice and the moral higher than the ritual. And even Sirach, a fervent supporter of priesthood and sacrifice (Ecclus. vii. 29 sq.), enunciates the same doctrine: "He that keepeth the law multiplieth offerings; he that taketh heed to the commandments sacrificeth a peace-offering. To depart from wickedness is a thing pleasing to the Lord, and to depart from unrighteousness is a propitiation" (Ecclus. xxxv. 1 sq.). And that the wise men feel themselves within the circle of the revealed religion is evident from their use of the name Jehovah, their frequent references to the "law," that is, *torah* or revelation, the "commandment," the "word," and the like; and such a sentence as this, "Where there is no vision (prophetic revelation, 1 Sam. iii. 1) the people cast off restraint" (xxix. 18), shows no unfriendliness to the prophets. The wise men had no quarrel with the institutions of Israel, nor with the public teachers and their operations; they occupied themselves more, however, with the life of the individual than the community, and sought to distil from

the particularistic thought in Israel principles which, both in morals and religion, should be universal and applicable wherever men lived.

Still this very universalism is a remarkable thing, and a different attempt has been made to explain it. It has been suggested that the wisdom, though some beginnings of it may have appeared during the prophetic period and while the autonomy of Israel as a state continued, must be in the main elements of its literature a thing posterior to the downfall of the state and the cessation of prophecy. Only in this way it is thought is it possible to explain the complete absence of all those ideas regarding Israel as a people, its relation to the heathen, and its future destiny, which fill the pages of the earlier literature. That inspiration and exaltation of mind which marked the prophetic age has disappeared and reflexion has taken its place. Enthusiasm for the state has died out because the state has perished, and is now represented by care for the individual. Prophecy has fulfilled its mission; it has lodged its principles in men's minds; it has seen itself fulfilled in the overthrow of the kingdom, but the hour of its triumph has been the hour of its death. Now follows the time of reflexion upon the prophetic truths, when the mind has accepted principles and risen through prophetic teaching to universal conceptions of God and the world, and an effort is made to apply them to the individual life. In short the age of the wisdom is the period of the return from exile, when Israel was no more a nation but a community of people, when it had no king of its own but obeyed a foreign ruler, and when prophecy speedily became dumb, partly because its mission had been fulfilled and partly because the chief condition of its exercise, the existence of the state, was wanting. In this condition of things the wise arose and exercised their functions; they do not allude to prophetic conceptions because, so far as these concerned the people in its nationality, they had in the meantime lost their meaning, and so far as they belonged to the general region of religious and ethical truth they had been accepted at least by the better minds among the people, and it is the aim of the wise to persuade every individual in the community to receive them and live by them. The wise indeed are the successors of the prophets; they inculcate the same truths as they did, but the subject whose ear they seek to gain is the individual and no more the state.

Such a theory, should it come to be accepted, would carry its compensations with it. It would fill with the liveliest activity a period in the life of Israel where a silence almost of death seems at present to reign. The centuries after Malachi are a great blank; if we could suppose them filled with the life and thought reflected in the charming literature of the wisdom, they would yield in interest to no period of the nation's history. And beyond doubt the wisdom continued to flourish in this age, for Ecclesiastes and later down the extra-canonical wisdom of Sirach are the fruits of it. If we consider Ecclesiastes, however, we find that it is the proper successor to the book of Job; it reflects the natural exhaustion of speculation on the great mysteries of God and providence which could not but follow the stormy conflict exhibited in Job. But in the two great collections of Solomonic proverbs such doubts regarding providence do not at all appear, and even in the other collections (except chap. xxx.) they are touched on lightly. The Proverbs appear to signalize the stage of Hebrew thought anterior to the book of Job. It may be said that Sirach does not debate such questions. This is true, but the reason is that he consciously declines to entertain them, "Seek not things that are too hard for thee"; "None shall say, what is this? wherefore is that?" (Ecclus. iii. 21, xxxix. 16), while to the proverbialists they

do not occur. Again, it is doubtful if any period in the history of Israel was marked by an absence of those national aspirations and hopes so prominent in the prophets; and if the wise do not allude to them it is not because the hopes were dead but because another direction of thought absorbed them. They are equally indifferent to the claims of the law. But, at whatever time the Levitical legislation arose or was codified, it is certain that at no period was it observed as it was after the restoration. And yet there is no allusion to it in the Proverbs; the "law" referred to is not the ritual but the ethical law as in the prophets; it is the law of one's mother, of the wise, of divine revelation in general, but never specifically that of the priest. In Sirach on the contrary the wisdom herself is identified with "the law which Moses commanded us for a heritage unto the assemblies of Jacob" (Ecclus. xxiv. 23). The truth is that the wisdom is a direction of thought differing from the main line of thought in Israel at any time, and yet a direction which we should expect and which we desiderate at all times. It is a force which was disrupting the particularism of the Jehovah religion from within just as the events of history shattered it from without, and bringing to view its inherent universalism. The prophets direct their attention mainly to the state, and they appear at irregular intervals. It is when the lion roars that they give the alarm (Amos iii. 8). Their voice is heard only when the tempest is rising, when some crisis in the people's history is approaching. We can hardly doubt that the intervals were filled up by the operations of men who pursued a calmer method, such as the wise, who were the "reprovers" and monitors frequently alluded to by the prophets themselves (Hos. iv. 4; Amos v. 10; Jer. xviii. 18). There is some danger of pushing the principle of development to an extreme so as under the influence of too ideal a conception of progress to divide the history and thought of Israel into sections by drawing straight lines across it, as Ezekiel in his vision divided the holy land into rectangular belts. No people moves forward on one line or in a mass. Alongside of the main current of thought and progress there are always minor currents running. And finally, while there are many proverbs that from their nature can hardly be placed in the period of the restoration, there are really none that from their internal character require to be dated so low. The proverb already quoted, "Where no vision is the people cast off restraint" (xxix. 18), must be contemporaneous with the prophetic period. The other, "My son, fear the Lord and the king" (xxiv. 21), would scarcely be spoken later than the monarchy (cf. 1 Kings xxi. 10). Many of the references to kings are no doubt general, though they are more natural under the native kingdom than at any other period (e.g., xvi. 12, xx. 8); but such a saying as this, "A divine sentence is on the lips of the king, his mouth shall not transgress in judgment" (chap. xvi. 10), seems to take us back to the more ancient days in Israel when the king actually judged causes in person. And undoubtedly the national tradition at the time of the composition of Job, as we see it reflected in the speeches of that book, was that the moral wisdom was so ancient as to be of immemorial antiquity.

The questions regarding the age of the individual collections contained in the present book and the age of the book as a whole are complicated.

1. It is an unfortunate thing that the headings cannot be absolutely relied on. Such headings are often founded on tradition, or are merely suggestions of later editors or collectors. The heading of the collection xxv.-xxix., "These are also proverbs of Solomon, which the men of Hezekiah copied out," does not of course date from the men of Hezekiah, for the word "also" shows that it is due to the editor who brought the collection into our present book, in which other proverbs of Solomon, viz., x.-xxii., already stood. There is no reason, however, to doubt the historical accuracy of the

inscription. This collection is at least as old as the end of the 8th century. At this period the proverbs contained in it were considered and called Solomonic. This of course does not guarantee that every proverb in the collection is by Solomon, though it guarantees the antiquity of the maxims, for the individual proverbs in a collection will always be older than the collection itself, and some of them may be of great antiquity. The term "copied out" implies that the men of Hezekiah confined themselves to written sources. We have little knowledge how the wise conducted their operations. Probably their instructions were in the main given orally. But small collections of their sayings were occasionally made by themselves or by others. Several such collections were in existence in Hezekiah's days, and his scribes gathered them into one book. The usual extent of such small codes may be inferred from some of those embodied in our present book, e.g., xxii. 17-xxiv. 22, xxiv. 23-34, and xxx. There is no probability that the term "copied out" implies that the men of Hezekiah proceeded critically and made a selection from a large mass of proverbs of such as they considered Solomonic, neither can their collection have been a gleanings made from a number of small codes after the large code x.-xxii. had already been extracted from them. They can hardly have been acquainted with x.-xxii., otherwise their code would not have contained so many duplicates of maxims in that collection. It is certainly not improbable that Hezekiah's collection forms the oldest element in our book. Many of the proverbs contained in it have the stamp of antiquity. It comprises almost all the proverbs that we still use. Such sayings as "iron sharpeneth iron," "as face answereth to face in water," "the dog is returned to his vomit," "bray a fool in a mortar," phrases like "heap coals of fire upon his head," "singing songs to a weary heart," "good news from a far country," "the curse causeless," "a whip for the horse, and a bridle for the ass, and a rod for the fool's back," are examples. Almost all the proverbs in xxv.-xxvii. contain a comparison, and some are of great beauty, as for example, "an earthen vessel glazed with silver dross, so are fervent lips and a bad heart." The youngest elements in this collection are found in xxviii.-xxix., which approach nearer the abstract and analytic manner of many of the proverbs in x.-xxii.

2. The passage i. 8-ix. is in all likelihood by one author, though some of the individual maxims contained in it may have been drawn from foreign sources (comp. vi. 9 sq. with xxiv. 30 sq.), and does not appear to be of very high antiquity. The general preface extends at least to xxii. 16; but, while its author says, "The proverbs of Solomon, son of David" (i. 1), a new inscription, "The proverbs of Solomon," heads x. This implies that i.-ix. were not considered Solomonic: the proverbs properly so-called commenced with the tenth chapter. Several things point towards a particular age as that to which the passage belongs. (1) The passage is probably prior to the book of Job, for the personification of wisdom seems referred to in that book (xv. and xxviii., though xxviii. may be later than the main portions of the book). The age of Job is no doubt uncertain, but it can hardly be considered anterior to the exile, nor yet much later. (2) The descriptions given of wisdom taking her stand by the broadways and at the gates and addressing the thronging crowds of men (i., viii.), as well as the picture of the strange woman prowling in the streets at nightfall (vii.), suggest that the writer had the idea of a large and populous city present to his mind. This could be no other than Jerusalem, and certainly Jerusalem before its destruction. The miserable city of the restoration could not until many generations after the return have afforded materials for the ideal before the author's eye, for nearly a century after the first exiles returned great part of it was still in ruins (Neh. vii. 4). Though the author warns the youth of his day against disorderly and violent men, his references to life suggest a condition of general comfort and plenty. (3) On the other hand the personification of the wisdom marks the highest point to which Hebrew thought on the world rose, and cannot belong to an early age. It is scarcely conceivable except at a time when the operations of the wise had been long pursued. Wisdom, pausing in the work of expounding providence and the laws of human happiness, which she had long instinctively pursued with self-forgetful fascination in her task, becomes self-conscious, and turning her eyes upon herself displays her own graces and beauty before the sight of men. A philosophy of wisdom has now been reached. These facts together point to a time not very long anterior to the destruction of Jerusalem, possibly about a century after the men of Hezekiah made their collection. With this agrees the language of the piece, which, though generally good, has several marks of a somewhat late age, e.g., the frequent formation of abstracts in *-uth*.

3. It is more difficult to form an opinion regarding the large code, x.-xxii. It has generally been considered the oldest collection in our book: and without doubt many of the proverbs contained in it may be old, as old as those in Hezekiah's collection, though others may be of more recent origin. From the nature of such general maxims there is little about them to suggest one age in preference to another. The grounds, however, on which these proverbs have been considered the oldest in the book hardly support such

a belief. These grounds are partly the form of the proverbs and partly the nature of their contents compared with the other collections. In form the collection consists exclusively of distichs, and in large parts of antithetical distichs. But, though the distich may be the oldest form of proverb, the inference can hardly be drawn that all distichs are ancient; the distich continued the prevailing type at all times, being still largely used by Sirach, and all that we are entitled to say is that some distichs are older than any proverbs that have another form. But many of the antithetical distichs for which a high antiquity is claimed are probably comparatively modern. Their literary style is too finished and elaborate to possess a high antiquity. There is an abstractness in them, and an artificial balance of member against member and word against word which suggests high literary culture and long use of the arts of the proverbialist. Further the extremely promiscuous nature of the collection, the repetitions in it, and the frequent occurrence of proverbs which are but modifications of others are proofs that it contains elements belonging to very different periods. The conjecture that Solomon himself put forth any collection of his proverbs has little to support it. At all events neither this whole collection nor any part of it in its present shape can have come from the hand of one who was the author of any great number of the proverbs contained in it. Nor can its present confusion be sufficiently explained by supposing with Ewald that an original ancient and orderly collection has suffered mutilation and fallen into disorder through repeated transcription and strong interpolation. That collections of proverbs were particularly liable to interpolation appears from the Septuagint, but the incoherence of our present code is such that it must have characterized it from the beginning. When we find one proverb repeated verbally (xiv. 12=xvi. 25), a number of others having the first member identical but differing in the second, and again a number more differing in the first member but identical in the second, we are led to infer that many of the proverbs before coming into the collection had a long history of oral transmission and currency, during which they underwent great changes, that like defaced coins they were thrown into the mint and came forth with a new image and superscription to circulate again among men, and that the code as a whole has been drawn largely from oral sources. While many of the maxims in such a code may be very ancient, the collection as a whole may be pretty late. Judged by contents, there is nothing in it that might not belong to the prophetic age or which would compel us to bring it in its present form below the exile. Some references in this collection, e.g., those to kings, when compared with similar allusions in Hezekiah's code, are thought to reflect an earlier and a happier time. The king is spoken of in a complimentary way, while in Hezekiah's collection the evils of corrupt government are bewailed and the *misera contribuens plebs* comes to the front. But the argument that proverbs in praise of a wise monarch must have originated under wise monarchs and conversely is not particularly strong; if the men of Hezekiah had felt the force of it they would scarcely have set a number of equivocal references to kings at the head of a collection formed under the auspices of that exemplary monarch. The history of the monarchy of Israel, both north and south, was sufficiently chequered to give the people experience of every kind of rule. Solomon himself was not a model prince, and neither in his nor his successor's days were the people unfamiliar with oppressive exactions. The references to rulers in all the collections are general reflexions from which historical conclusions can hardly be drawn; in xix. 10 the rise of a slave to rule over princes is spoken of, a thing unknown in Israel; and similar general allusions to rulers occur both in Ecclesiastes and in Sirach (Ecclus. vii. 4 sq.).<sup>1</sup>

4. There is nothing in the contents of the small collections xxii. 17-xxiv. 34 to suggest a date lower than the exile (cf. xxiv. 21). On the other hand the despair of attaining to the knowledge of God expressed in ch. xxx. reminds us of Job xxviii. and Ecclesiastes, and the passage may belong to the post-exile period. The warning against adding to the words of God (xxx. 6) might also suggest the existence of canonical writings. The section is marked by peculiarities of language and manner. If the names Agur and Lemuel be real the passage might belong to a time when Israel and the tribes towards the south began to coalesce. The alphabetical poem with which the book is closed is probably not early, though there is little in it to suggest any precise age. Ezek. xxvii. 17 compared with xxxi. 16, 24 perhaps shows that in the time of this prophet Judah did not yet engage in the kind of manufactures mentioned in the poem.

The general heading i. 1-7 must be preface to at least i.-xxii. 16; it may extend to xxiv., or to xxix., or to the end of the book. Its relation to i. 8-ix. is of importance in reference to the date of the collection x.-xxii. On the one hand it is probable that the

preface comprises ver. 7, "The fear of the Lord is the beginning of wisdom." Some such general aphorism was necessary to clinch the statement regarding the uses of the proverbial literature. On the other hand the passage i. 8-ix. could scarcely have begun abruptly, "My son, &c." The general aphorism both closes the preface and introduces what follows. If this be the case the author of the preface is also author of i. 8-ix., and undoubtedly the preface agrees in style with these chapters. He is certainly also the editor of x.-xxii. It is possible that he was also the collector of the proverbs in this code. In any case this important collection would be anterior to the exile, though it is not likely that the collection was made long before the destruction of Jerusalem. The agreement, however, between the style of the preface and that of the first nine chapters is supposed by others to be due to imitation on the part of the author of the preface. This is possible, though less natural. On such a supposition, however, the preface would be younger in date than i. 8-ix., and the conclusion as to the age of x.-xxii. would fall to the ground. This collection in that case might be later than i.-ix. and contain proverbs of the post-exile period. The preface refers to "the words of the wise," and it is probable that it extends to xxiv. Whether the author of the preface and editor of i.-xxiv. added also xxv.-xxix. is uncertain; the word "also" (xxv. 1) implies that this independent code was added when x.-xxii. had already received a place in the general collection.

The Septuagint version exhibits great variety of reading, and has many additions and also remarkable omissions. The additions are usually of little worth, though with exceptions, as the word "not" in v. 16. Critically the omissions are of more interest than the insertions. This version transfers xxx. 1-14 to a place after xxiv. 22; then follows the remainder of chap. xxiv. After this comes xxx. 15-xxxi. 9, then the code xxv.-xxix., and finally xxxi. 10-31. The objects of this transposition are not apparent; but the effect of the changes here and elsewhere has been to obliterate all traces of other than Solomonic authorship from the book, and possibly this was intended.

*Literature.*—Important commentaries are those of Schultens, M. Stuart, Ewald, Hitzig, Deltzsch, Bertheau (*Exeg. Handb.*, 1st ed.; 2d ed. by Nowack). Valuable on the text is Lagarde, *Anmerkungen zur Griech. Uebersetzung der Proverben*; also Deyserinck, *Krit. Scholien* (reprint from *Theol. Tijds.*, 1881). Works on the Wisdom are—Bruch, *Weisheitslehre der Hebräer*; Hooykaas, *Geschiedenis der Beoefening van de Wijsheid onder de Hebrëen*; Oehler, *Grundzüge der Alttest. Weisheit*. The literature is fully given in Lange's *Comm.*, and the introductions; see especially the valuable section in Kuenen's *Hist. Krit. Onderzoek*. There is a special treatise on xxx.-xxxi. 9 by Mühlau. (A. B. D.)

PROVIDENCE, a city of the United States, joint capital with Newport of the State of Rhode Island, and seat of justice of Providence county, is situated in 41° 49' 22" N. lat. and 71° 24' 48" W. long. It is the largest

Plan of Providence.

city in Rhode Island, and both in wealth and population ranks next to Boston among the cities of New England. It is built on both sides of Providence river, at the head of Narragansett Bay, 35 miles from the ocean, and has the Seekonk river and the harbour on its eastern boundary.

<sup>1</sup> The statement of Ewald that the *article* is rarer in this collection than in that of Hezekiah is not supported by the facts; on the other hand the anticipative Aramaean suffix, not found in xxv. sq., is common to the two other large codes, i.-ix. and x.-xxii.

Its area, which is extremely diversified, comprises 14.76 square miles, rising to a height of 204 feet on the east side. On the extreme southern boundary lies Roger Williams Park (102 acres), bequeathed to the city in 1871. The buildings of Brown University occupy a commanding position on the East Side. This institution, the seventh college organized in the country, was originally founded at Warren, R.I., in 1764, as "Rhode Island College." It was removed to Providence in 1770, and took its present name (that of its principal benefactor) in 1804. University Hall was erected in 1770, and of the eight other buildings three have been built since 1877. Of its governing board five-eighths must, by its charter, be Baptists, but the faculty and the students have always represented a wide variety of religious beliefs. In 1884 it had 248 students and 20 professors and instructors. It possesses a library of 62,000 volumes, preserved in a fire-proof structure, costing about \$120,000. Among other educational institutions are the Friends' school (1819), the academy of the Sacred Heart (Roman Catholic) (1873), the university grammar school, the Berkeley school, and the English and classical school. The city system of public schools comprises one high school (22 teachers and 634 pupils), and 87 other schools of various grades. The number of school buildings is 54, of teachers 328, and of pupils 15,484. The Rhode Island Historical Society was founded in 1822 and occupied its present building in 1844, and the Providence Franklin Society (scientific) dates from 1823. The Providence Athenaeum, founded 1838, has a library of over 43,000 volumes, and the Providence public library (1878) nearly 32,000 volumes. The Rhode Island hospital, completed in 1868 at a cost of more than \$450,000, has about 80 patients. The Butler hospital for the insane (1847) accommodates about 200 patients, and occupies about 120 acres of land overlooking the Seekonk river. The Dexter asylum (or city almshouse), erected in 1827, receives about 125 inmates, and devotes about 30 acres to a very profitable system of market-gardening. The State penal and reformatory institutions, formerly within the city limits, were in 1878 removed to new quarters in Cranston, about three miles south of the city boundary. The State-house, erected in 1762, stands on the East Side, as does also the court-house (1877), erected at a cost of \$400,000. On the West Side is the city hall (1879), costing nearly one million dollars. In front of the latter stands the Soldiers' and Sailors' Monument (1871). There are two principal theatres, erected in 1871 and 1877. Among the churches may be mentioned the cathedral of St Peter and St Paul (Roman Catholic), begun in 1878; also Grace, All Saints, and St John's (Protestant Episcopal), the last dating from 1811; the First Baptist (erected 1775) and the First Congregational (1816). The number of church organizations is about ninety. The predominant interest of Providence is no longer commerce<sup>1</sup> but manufactures, the census of 1880 ranking it sixteenth among American cities in the value of its products. Out of the total, the value of the cotton products was \$2,250,273, this being one of the chief cotton markets of the Northern states; the woollen and worsted goods, \$7,139,947; iron manufactured products (including steam-engines, boilers, locomotives, sewing-machines, rifles, screws, hinges, files, machinery, &c.), \$4,757,401; and gold and silver manufactured products (in which department this is among the first), \$6,865,192.

<sup>1</sup> The foreign commerce, chiefly with China and the East Indies, was formerly considerable, but received a check early in this century. In 1884 the merchandise imported at the custom-house was valued at \$337,800, and that exported \$25,296. 59 vessels (10,864 tons) entered from foreign ports, and 41 (5012 tons) cleared. During 1883 the eight lines of steamers centring here carried \$500,000 of goods daily.

An extensive system of tramways, comprising 45 miles of track and employing more than 1000 horses, connects all portions of the city and suburbs with the centre. The Providence telephone exchange, organized in 1879, controls 1200 miles of wire and has (1885) about 2100 connexions. The city is lighted both by gas and the electric light. It has also an extensive system of water supply and sewerage. There are fifteen newspapers, four being dailies. The population has increased as follows:—

1708.....	1,446	1810.....	10,071	1860.....	50,666
1730.....	3,916	1820.....	11,767	1870.....	68,904
1774.....	4,321	1830.....	16,836	1880.....	104,857
1790.....	6,380	1840.....	23,172	1885.....	118,070
1800.....	7,614	1850.....	41,513		

From 1855 to 1883 inclusive there has been an average of 1 birth in 36.37 of the population, and 1 death in 50.89. The value of real estate in 1883-84 was \$91,642,100, and of personal estate \$30,854,400. The municipal receipts for the same year were \$3,417,593.62; expenditure, \$3,196,382.20; debt, \$8,142,223.77. In the ratio of its valuation to its population Providence ranks as one of the wealthiest of American cities.

The first settlement within the limits of Providence was made in 1636 by Roger Williams, who had been obliged to leave the neighbouring colony on account of his religion and political opinions. He obtained a large tract of land from the Indians by friendly negotiations, the original "deeds" being still preserved in the city archives, and gave the name of Providence to the settlement. The town of Providence united with two others in 1643-44 in applying for and receiving from the Parliamentary government in England the first charter of the colony. The most of the houses were destroyed during an attack by the natives in 1676. The War of Independence in 1775-83 also had the effect of very materially prostrating the commerce and trade of the town. In 1832 the town form of government was exchanged for that of a city, the charter providing for a division into six wards. The present number of wards is ten. (W. E. F.)

PROVINCE (*provincia*, etymology uncertain), in the Roman sense, may be defined as the department or sphere of duty assigned to one of the higher magistrates (the consuls and prætors).<sup>2</sup> But when, with the spread of the Roman arms, the government of conquered countries grew to be one of the most important duties of the higher magistrates, the term province, from designating the government of a conquered country as one particular duty of a Roman magistrate, came to be used generally as a designation of the country itself. It is to province in the sense of a subject territory lying outside of Italy and governed by Roman magistrates that the following remarks will apply. As distinguished from Italy, the provinces paid tribute to Rome, for, at least from the time of the Gracchi, it was a recognized constitutional principle that the provinces were the estates of the Roman people and were to be managed for its benefit. Under the republic the constitution of a province was drawn up by the victorious Roman general assisted by ten commissioners appointed by the senate from its own body, and the province was henceforth governed on the lines laid down in this constitution or charter (*lex provinciae*). For administrative purposes the province was divided into districts, each with its capital, the magistrates and council of which were responsible for the collection of the district taxes. For judicial purposes the province was divided into circuits (*conventus*), and in the chief town of each circuit the governor of the province regularly held assizes.

Cities taken by the sword were destroyed, and their lands were turned into Roman domains and were let out by the censors at Rome to private persons, who undertook to pay a certain proportion of the produce. Royal domains, such as those of Syracuse, Macedonia, Pergamum,

<sup>2</sup> Only those magistrates who had *imperium* (military power) had a province. When the province of a quaestor is mentioned it refers to the province of the consul or prætor to whom the quaestor is subordinate. In familiar language any business was called a province.

Bithynia, and Cyrene, were also confiscated. On the other hand communities which surrendered without offering an obstinate resistance were usually allowed to retain their personal freedom and private property, and their chief town was left in the enjoyment of its territory and civil rights, but all the lands were subjected to a tax, consisting either of a payment in kind (*rectigal*) or of a fixed sum of money (*tributum, stipendium*), and in some cases a custom-duty (*portorium*) was levied. It is to this latter class of communities (the *civitates rectigales* or *stipendiarias*) that the large majority of the provincial states belonged. In a better position were those states whose freedom was guaranteed by Rome on the ground of old alliances or special loyalty. Their freedom was recognized either by a treaty or by a decree of the Roman people or senate. As a decree of the people or senate could at any time be recalled, the position of the free states without a treaty was more precarious than that of the treaty states (*civitates foederatae*). The latter, though not allowed to meddle in foreign politics, enjoyed a certain amount of internal freedom, retained their lands, paid no taxes, and were bound to render those services only which were expressly stipulated for in the original treaty, such as furnishing ships and troops, supplying corn at a certain price, and receiving Roman officials and soldiers *en route*. Amongst these treaty states were Massilia (Marseilles), Athens, Rhodes, and Tyre. The privileges of the free but not treaty states were somewhat similar, but, as stated, more precarious. All political distinctions, save that between slave and freeman, disappeared when Caracalla bestowed the Roman franchise on the whole empire.

**Provincial Diets.**—Apart from the government by Roman officials, every province appears to have had, at least under the empire, a provincial assembly or diet of its own (*concilium* or *commune*), and these diets are interesting as the first attempts at representative assemblies. The diet met annually, and was composed of deputies (*legati*) from the provincial districts. It arranged for the celebration of religious rites and games, especially (under the empire) for the worship of the emperor, the neglect of which was severely punished. The actual celebration was under the conduct of the high priest of the province, a person of much dignity and importance, perhaps the forerunner of the Christian bishop. The diet also decreed the erection of statues and monuments; it passed votes of thanks to the outgoing governor, or forwarded complaints against him to Rome; and it had the right of sending embassies direct to the senate or the emperor.

**The Provincial Governor.**—The provinces were administered by governors sent direct from Rome, who held office for a year. From the formation of the first provinces, in 227 B.C. down to the time of Sulla (82 B.C.) the governors were praetors (see *PRÆTOR*); from the time of Sulla to that of Augustus the praetors remained in Rome during their year of office, and at the end of it assumed the government of a province with the title of *propraetor*. This applies, however, only to provinces which were in a settled state and could consequently be administered without a large military force. A province which was the seat of war, or was at least in a disturbed state, was committed to the care either of one of the consuls for the year or of a commander specially appointed for the purpose with the title of *proconsul*, who might be one of the consuls of the preceding or of a previous year, or else a former praetor, or even, in rare cases, a private individual who had held neither consulship nor praetorship. Thus the distinction between consular (or *proconsular*) and praetorial (or *propraetorial*) provinces varied from year to year with the military exigencies of different parts of the empire. At the close of the republic, however, we find even such a peaceful province as Asia administered by a *proconsul*. In the earlier period of the republic the senate either before or after the elections determined which provinces were to be governed by consuls and which by praetors, and after their election the consuls arranged between themselves by lot or otherwise which of the provinces nominated by the senate each should have, and similarly with the praetors. But in order to guard against partiality the Sempronian law of 123 B.C. provided that the senate should yearly

nominate the two consular provinces before the election of the consuls, and that the consuls should after their election but before their entry on office arrange between themselves which of the two provinces each should have. The Pompeian law of 53 B.C. enacted that no one should hold the governorship of a province till at least five years after his consulship or praetorship. This law was repealed by Caesar after the battle of Pharsalia, but was re-enacted under Augustus; it severed the connexion which had previously existed between an urban magistracy and the governorship of a province, and turned the latter, from the mere prolongation of a Roman magistracy, into an independent office. Like magistracies at Rome a provincial governorship was regularly held for one year; but, unlike them, it could be prolonged, formerly by a vote of the people, later by a decree of the senate. The Julian law of Caesar (46 B.C.) enacted that the governorship of a consular province should be held for two, that of a praetorian province for one year. The necessary supplies of men and money were voted to the governor by the senate. His staff consisted of one or more lieutenants (*legati*), a quaestor, and numerous subordinates. The lieutenants were nominated by the senate from men of senatorial rank; if they proved incompetent, the governor dismissed them; if they showed ability, he entrusted them with military or judicial functions. As to the quaestor, see *QUAESTOR*. Besides these the governor took with him from Rome a number of young men of the upper classes to assist him in the government. These were known as the companions (*comites*), or suite of the governor, sometimes, but incorrectly, as the praetorian cohort (see *PRÆTORIAN*). These members of his suite were chosen by the governor himself, who was responsible for them, but they were maintained at the expense of the state, and under the empire received regular pay. In addition there was a crowd of headles, clerks, couriers, criers, doctors, dragomans, &c., not to speak of freedmen and slaves for the personal service of the governor. Under the republic the governor was not allowed to take his wife with him to his province; under the empire he might do so, but he was answerable for her conduct. Before setting out for his province the governor, clad in the purple military robe of his office, offered sacrifice on the Capitol; then immediately after receiving the *imperium* or military command he marched out of the city (for the *imperium* could only be exercised outside of Rome and was forfeited by staying in the city), preceded by his servants (*liberarii*), and accompanied by his suite. He was bound to travel direct to his province; the means of transport were supplied partly by the state, partly by the provinces through which he travelled. His year of office began from the day he set foot in his province, but the time of arrival varied with the length and difficulty of the route. In the hands of the governor all powers military and civil were united. He commanded all the troops in the province, and had power to raise levies of Roman citizens as well as of provincials, and to make requisitions of war material. He possessed both criminal and civil jurisdiction; as criminal judge he had the power of life and death, and from his sentence none but Roman citizens could appeal; as civil judge he was guided partly by the charter of the province (*lex provinciae*), partly by the edict which it was customary for him to issue before his entrance on office (compare *PRÆTOR*), partly by the original laws of the country so far as their validity was acknowledged by the charter or by the governor's own edict. Under the empire Gaius wrote a commentary on the provincial edict, and it is usually supposed that this was a general edict drawn up for use in all the provinces and superseding all separate edicts for the different provinces. Mommsen, however, is of opinion that Gaius only commented on the edict of a particular province.

**Condition of the Provinces under the Republic.**—Under the republic the Roman people regarded the provinces as so many estates from which they were to derive revenue. The weal or woe of the provincials was of no moment, but the development of the material resources of the provinces was of great moment. Hence agriculture and commerce were encouraged, settlements were made, roads and aqueducts were constructed; in short, the Roman aimed at exploiting his empire by a system of prudent economy as far as possible removed from the blind rapacity which has turned the empire of the Turk from a garden into a wilderness. But the Roman governors were too apt to look on their provinces as their own peculiar prey; they had usually bought their way to office at vast expense, and they now sought in the provinces the means of reimbursing themselves for the expenditure they had incurred at Rome. The annual change of governor was thus a frightful calamity to the provincials, for every year brought a repetition of the same extravagant demands to be met by the same or, as the province became exhausted, still heavier sacrifices. Redress was to be had originally by a complaint to the senate; after 149 B.C. there was a regular court established at Rome for the trial of cases of oppression (*repetundæ*) by provincial governors. But, even when after much trouble and expense the provincials had arraigned their oppressor, it was difficult to secure his condemnation at the hands of juries composed (as they usually were) of men who had a fellow-feeling for the offender because they had themselves com-

mitted or hoped for means of committing similar offences. Besides the governor, two classes of harpies joined in wringing the uttermost farthing from the unhappy provincials. These were the publicans or farmers of the taxes, and the money-lenders (*negotiatores*), who supplied a temporary accommodation at ruinous rates of interest. Both these classes were recruited from the ranks of the Roman knights, and, since from the legislation of Caius Gracchus (122 B.C.) the juries were drawn at first exclusively and after Sulla's time, (81 B.C.) partially from the knightly order, the provincial governor could not check the excesses of those blood-suckers without risking a condemnation at the hands of their brethren. Accordingly he generally made common cause with them, backing their exactions when needful by military force.

*The Provinces under the Empire.*—Under the empire the provinces fared much better. The monarchy tended to obliterate the distinction between Romans and provincials by reducing both to a common level of subjection to the emperor, who meted out equal justice to all his subjects. The first centuries of our era were probably for some of the countries included in the Roman empire the happiest in their history; Gibbon indeed fixed on the period from the death of Domitian to the accession of Commodus (98–180 A.D.) as the happiest age of the world.

Augustus, in 27 B.C., divided the provinces into imperial and senatorial. Those which, from their proximity to the frontier or the turbulence of their population, required the presence of an army were placed under the direct control of the emperor; those which needed no troops were left to be administered by the senate. (1) The senatorial provinces were ruled by an annual governor as under the republic. Of these provinces Augustus ordained that Africa and Asia should be consular, the rest prætorian; but all the governors of the senatorial provinces were now called *proconsuls*. Their powers and dignities were much the same as they had been under the republic, except that they had now no troops, or only a handful to maintain order. (2) The imperial provinces were governed by imperial lieutenants (*legati Caesaris*), who were nominated by the emperor and held office at his pleasure; all of them had the power of the sword (*ius gladii*). For the administration of the finances these lieutenants had procurators under them, while the governors of the senatorial provinces continued to have questors as under the republic. Another class of imperial provinces consisted of those which from the physical nature of the country (as the Alpine districts) or the backward state of civilization (as Mauretania and Thrace) or the stubborn character of the people (as Judæa and Egypt) were not adapted to receive a regular provincial constitution. These were regarded as domains of the emperor, and were managed by a procurator (in the case of Egypt by a præfect, see *PRÆFECT*) nominated by and responsible to the emperor.

Under the empire all provincial governors received a fixed salary. Complaints against them were brought before the senate, and the accusers were allowed a senator to act as their advocate. The lengthened periods during which the governors, at least in the imperial provinces, held office, together with the oversight exercised by the emperor, alleviated materially the position of the provincials under the empire. In order to keep himself well informed of what was passing in the empire, Augustus established a post whereby official despatches were forwarded by couriers and official persons were conveyed by coaches. The post, however, was only for the use of the Government; no private person was allowed, unless by an exceptional concession, to avail himself of it.

(J. G. FR.)

**PROVINS**, a town of France, at the head of an arrondissement of the department of Seine-et-Marne, at the junction of the Durtain with the Voulzie (an affluent of the Seine), 59 miles south-east of Paris by a branch rail-

way which rejoins the main line from Paris to Belfort at Longueville (4 miles from Provins). While the town derives a certain reputation from its mineral waters (which contain iron, lime, and carbonic acid, and are used for bathing and drinking), and is also known from its trade in roses (incorrectly called Provence roses) for certain minor industries (such as the making of "conserves" and colouring bonbons), a far higher interest attaches to it as a place which during the Middle Ages enjoyed great prosperity and still preserves, in proof of its former importance, a number of historical monuments. There still remains a great part of the 13th-century line of fortifications, which makes a circuit of about 4 miles, encloses an area of about 300 acres, is strengthened at intervals by towers, generally round, and now, being bordered with fine trees, forms the principal promenade of the town. The large tower, situated within this line and variously known as the king's, Caesar's, or the prisoners' tower, is one of the most curious of the 12th-century keeps now extant. The base is surrounded by a thick mound of masonry added by the English in the 15th century when they were masters of the town. The tower serves as steeple to the church of St Quiriace, which, dating its foundation from the 12th century, presents some exquisite features and preserves among its treasures the pontifical ornaments of St Edmund of Canterbury. The palace of the counts of Champagne, some fragments of which also belong to the 12th century, is occupied by the communal college. The old tithe-barn is a strange erection of the 13th century with noteworthy fireplaces, windows, and vaulting. Various portions of the church of St Ayoul date from the 11th, 13th, 14th, and 16th centuries respectively; but it is in a state of great dilapidation, and part of it is used as a fodder-store. Ste Croix belongs partially to the 13th century. On Mont Ste Catherine opposite Provins the general hospital occupies the site of an old convent of St Clare, of which there remains a cloister of the 13th century. The population of the town in 1881 was 6949.

Provins begins to figure in history in the 9th century. Passing from the counts of Vermandois to the counts of Champagne it rapidly attained a high degree of prosperity. Its fairs, attended by traders from all parts of Europe, were of as much account as those of Beaucaire. They were held twice a year, in spring and autumn, and fixed the price of provisions for the intervening months. In the 13th century the population of the town is said to have reached 60,000; but the plague of 1348 and the famine of 1349 proved exceedingly disastrous. The War of the Hundred Years, during which Provins was captured and recaptured, completed the ruin of the unfortunate town. During the religious wars it sided with the Catholic party and the League, and Henry IV. obtained possession of it in 1592 only after thirteen days' siege.

See Félix Bourquelot, *Histoire de Provins*, 2 vols., 1840.

**PROXY**. See **PROCTOR**.

Another, which became the Bethlehem of the West, as Rome had become its Jerusalem, was Loreto, where, ever since 1295, the Santa Casa, declared to be the home of the Holy Family, miraculously transported from Nazareth, has been frequented by pilgrims till very recent times, when its popularity has waned. Other famous shrines, some few of which even still attract yearly crowds of pilgrims, are Einsiedeln in Switzerland; Assisi, Oropa, Varcse and Vicovaro in Italy; Monserrat and Guadalupe in Spain; Mariazell in Austria; Oetting and Eberhardsclausen in Germany; Walsingham, Becket's shrine at Canterbury, Peterborough, St Davids, and Holywell in England and Wales; St Andrews in Scotland; Chartres, Notre Dame de Liesse, Notre Dame de Rocamadour, and Notre Dame des Victoires, with Ste Anne d'Auray in Brittany, in France; and Hal in Belgium. Devotion to these shrines was encouraged and developed by copious indulgences annexed to them; but this system in the long run became adverse to pilgrimages, because exactly the same privileges were annexed at a later time to acts much more easy of performance. Thus, the wearers of the cord of St Francis, every time of reciting certain brief prayers, acquire all the indulgences attached to the holy places of Palestine, Rome, Assisi, and so forth, and have naturally little inducement to perform toilsome and costly journeys thither.

There is a further small class of pilgrimages, differing from all others in being neither permanent nor yearly, but periodical at various long intervals. They are usually connected with the exposition of the principal relic or relics in some important church, an event which rarely occurs. Such are the pilgrimages of Cologne, to the shrine of the Three Kings, and that of Treves, where the alleged seamless coat of Christ has been displayed for popular devotion, and has been visited by vast crowds of pilgrims.

Pilgrims in the Middle Ages were known by a peculiar garb and various badges, the hood and cape, the staff and scrip and water-bottle, and the low-crowned hat, turned up in front, and fastened with strings, being common to all, while the palm specially marked a pilgrim from the Holy Land; a shell, one from Compostella; a bottle or bell, one from Canterbury, and so forth. They had many privileges and advantages. They were exempt from toll, their persons were inviolable, and any injury done to them incurred the penalty of excommunication; they were entitled to shelter, fire, and water in all convents on their road, and the needier ones to food in addition; and there were resting-stations erected for them on all the great lines of travel, sustained sometimes by voluntary offerings, and sometimes by public imposts; while in Rome, above all, institutions for their reception and relief were established early, and are still in active operation.<sup>1</sup> Nevertheless they declined in repute, not only by reason of the feigned devotees who joined them for purposes of vagrancy and mendicancy, and even from worse motives, but because many notorious criminals were customarily sent on pilgrimage as a punishment, with no care to isolate them from their innocent companions. The general charge of moral deterioration as a result of pilgrimage, which recurs from the fourth century onwards, is specifically brought by Langland in respect of truthfulness:—

"Pilgrims and palmeres pligheten hem togidere,  
For to seken seint Jame and seintes at Rome.  
They wenten forth in hire way, with many wise tales,  
And hadden leve to lyen all hire lif after."

—(*Vision of Piers Plowman*, pass. i. line 82).

lasted very long, for there are edicts of Louis XIV. and XV. forbidding foreign pilgrimage to French subjects without the written permission of their bishop, and the counter-signature of a state official, under pain of the galleys for life. They bear date 1671, 1686, and 1738.

<sup>1</sup> For more details, see Mr Seudamore's articles, "Holy Places" and "Pilgrimages," in Smith's *Dictionary of Christian Antiquities*.

Hence pilgrimages were attacked with the weapons of ridicule, and the most celebrated satires upon them are the chapter in *Reineke Fuchs*, describing Reynard's adventures as a pilgrim, and the yet wittier squib of Erasmus, *Peregrinatio religionis ergo*, in which he gives a sarcastic account of the pilgrimage to Walsingham, which had much to do with destroying the prestige of not only that particular one, but most others also. The French Revolution all but completed the work of the Reformation in causing pilgrimages to decline seriously, where they were not entirely abolished, in the West, though they were still able to maintain their ground in retired and unchanging places such as Brittany, various places in central Italy, and in Ireland, where the severely penitential pilgrimages of Lough Finn, Lough Dearg, and Croagh Patrick are not yet obsolete. There was a remarkable recrudescence of the spirit of pilgrimage under the pontificate of Pius IX., notably to the new sanctuaries of La Salette and Lourdes in France, which reached its height about 1872–73, but has shown signs of subsiding again since.

In the Eastern Church, pilgrimages have not for many centuries formed so important a part of popular religion as in Latin Christendom, and the number of frequented shrines is very small. In the Greek Church properly so called, Mount Athos, with its numerous monasteries, where the great yearly gathering is on the feast of the Transfiguration, ranks next to the visit to the Jordan (Tozer, *Highlands of Turkey*, i. 103). After Mount Athos comes a shrine in the island of Tenos, where, in the cathedral church of the Panagia Evangelistria, is preserved an icon of the Madonna, alleged to be wonder-working, and said to have been discovered by means of a dream in 1824; the annual concourse of pilgrims twice a year, on the feasts of the Annunciation and the Assumption, is very great. Three alleged pictures of the Blessed Virgin by St Luke—at Megaspelion, at Samelas in the mountains behind Trebizond, and at Stiri in Mount Helicon—are also much visited. Etchmiadzin is the chief Armenian pilgrimage, besides which are those of Kaisariyeh and Mush (Tozer, *Turkish Armenia*, pp. 161, 271). And finally, the chief Russian pilgrimages are to the Petcherskoilavra at Kieff (said to be visited by 200,000 pilgrims yearly), the Solovetsk monastery near Archangel, and the Troitsa, close to Moscow, besides many more locally popular shrines. (R. F. L.)

**PILLORY.** This was a mode of punishment by public exposure of the offender on a platform or scaffold long used in most countries of Europe, originating probably with the Anglo-Saxons, one of whose methods of punishment as described by Strutt is nearly identical with the instrument which eventually became known as the pillory. The etymology is not quite clearly made out. It is most probably connected with *pillar*, Fr. *pilier*, M. H. German *Pfihlaere*, but there are forms with an initial *s* (Prov. *espillori*, Low Lat. *spilorium*) which this derivation does not explain. The more usual French term is not *pilori* but *le carcan*. The Germans have *Preller*. *Healsfang* or *halsfang* (Anglo-Saxon for a catching of the neck) was the old English name. The word was also sometimes applied to the pecuniary mulct paid in commutation of the punishment. No punishment has been inflicted in so many different ways as that of the pillory. Sometimes the machine was constructed so that several criminals might be pilloried at the same time, but it was commonly capable of holding only one. Douce (*Illustrations of Shakespeare*) gives six representations of distinct varieties of this instrument. In Griffiths (*Chron. of Newgate*) and in a learned and exhaustive account of the pillory by Jewitt (*Reliquary*, April 1861), examples will also be found, and notably of the pillory for women, which differed in form from that in use for male offenders. It would

appear that it had not always been customary to subject women to this form of punishment; for them the thew or the tumbrel, which latter was probably the same as the ducking or cucking stool often spoken of in the early English laws in conjunction with the pillory, was reserved. These varieties are all reducible, however, to the simplest form of the pillory as *ordinarily known*, which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame so as to be exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle or carcan (hence the French name), which secured the heads and hands of several persons at the same time.

In the statutes of Edward I. it is enacted that every pillory or stretch-neck should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. Some of the offences punished in England by the pillory will be found enumerated in the statute 51 Hen. III. c. 6 (1266), comprehending chiefly indictable offences not amounting to felony (commonly called misdemeanours), such as forestalling and regrating, using deceitful weights and measures, perjury or subornation of perjury, libel, seditious writings, &c. Later on, the punishment of the pillory was ordained for courtesans, common scolds, and brawlers and other like delinquents both male and female, and in the later years of its existence, notably during the 17th and 18th centuries, it was much resorted to as a punishment for political offenders, who on some occasions experienced the roughest treatment at the hands of the mob, ill-usage resulting in some instances on record even in death. The intention of setting a criminal in the pillory was that he should become infamous and known as such afterwards by the spectators. Examples have not been wanting, however, in which much sympathy has been both felt and expressed by the populace for the individual subjected to this punishment. The duration of the punishment was usually assigned at the discretion of the judge who passed the sentence, though sometimes it was fixed by law. The form of the judgment was that the defendant should "be set in and upon the pillory"; he was consequently said to stand in the pillory, not at it.

The pillory was abolished in Britain, so far as related to all offences save perjury and subornation, in 1816 (56 Geo. III. c. 138), and finally altogether by statute 7 Will. IV. and 1 Vict. c. 23 in 1837. In the former Act power had been reserved to the court to pass sentence of fine or imprisonment or both in lieu of the pillory. The punishment was done away with in France in 1832 upon the revision of the penal code, and has now indeed been withdrawn from most of the modern systems of penal law.

**PILOT.** The English Merchant Shipping Act of 1854 (17 & 18 Vict. c. 104) defines a pilot as being a person duly licensed by any pilotage authority to conduct ships to which he does not belong as one of the crew. Pilots are in fact taken on board to superintend the steering of the vessel, where the navigation is difficult and dangerous, in consequence of their special knowledge of particular waters; and it is to this class alone that the term now applies, whereas in early times the pilot was the steersman, or the individual who conducted the navigation of a ship across the ocean and out of sight of land. The word seems to be of Dutch origin, and to mean primarily a person who conducts a ship by the sounding line (*peillood*). Cowell (*Law Dict.*), describing *lodemanage*, speaks of it as

the hire of a pilot for conducting a vessel from one place to another,—a *lodesman* (Ang. Sax. *lād-man*, a leader) being a pilot for harbour and river duty. During the period of his charge the whole responsibility of the safe conduct of the vessel devolves upon the pilot. Most systems of maritime law have made the employment of pilots compulsory, though this does not usually apply to ships of war. One effect of neglect or refusal on the part of the master of a ship to take a pilot is to discharge the insurers from their liability.<sup>1</sup> Excepting under extraordinary circumstances (such as where it is evident that he is acting rashly or is intoxicated, or is palpably incompetent) a master would not be justified in interfering with the pilot in his proper vocation. In England, societies or corporations have long been established for the appointment and control of pilots in particular localities; and of these the Trinity House, London, owing to the number of the pilots under its control, and the large extent of its jurisdiction, may be deemed the principal. The laws relating to pilotage were consolidated by 48 Geo. III. c. 104 (1808), which was amended by 6 Geo. IV. c. 125 (1825); further regulations were made by 16 & 17 Vict. c. 129 (1853), which incorporated the Cinque Ports with the Trinity House pilots; and all existing regulations on the subject were embodied in the Merchant Shipping Act 17 & 18 Vict. c. 101 (1854), already referred to, from which pilotage authorities within the United Kingdom derive their jurisdiction, and which regulates their powers, the licensing of pilots and their rights, privileges, liabilities, and remuneration (Maude and Pollock, *Law of Merchant Shipping*, 1861).

The laws of pilotage in the United States are regulated by the individual States according to the Acts of Congress.

**PILOT-FISH** (*Naucrates ductor*), a pelagic fish of the family of Horse-Mackerels, well known to sailors from its peculiar habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and sub-tropical seas, and is common in the Mediterranean, but becomes scarcer in higher latitudes. In summer pilots will follow ships as far north as the south coast of England into port, where they are generally speedily caught. This habit was known to the ancients, who describe the

Pilot fish.

*Pompilus* as a fish which points out the way to dubious or embarrassed sailors, and by its sudden disappearance indicates to them the vicinity of land; the ancient seamen of the Mediterranean regarded it therefore as a sacred fish. That the pilot follows sharks is an observation of much later date, which first appears in works of travel of the 17th century, the writers asserting that the shark never seizes the pilot-fish, and that the latter is of great use to its big companion in conducting it and showing it the way to its food. It is, however, extremely doubtful whether the pilot's connexion with a shark serves a more special purpose than its temporary attachment to a ship. It accompanies both on account of the supply of food which it derives from them, picking up the crustaceans, cirripeds,

<sup>1</sup> In a measure before parliament in 1884, but not passed, it was contemplated to wholly abolish compulsory pilotage, releasing owners or masters of ships not employing pilots from all pilotage dues or rates and from any penalty for not employing a pilot.

or other marine animals swarming about the ship's bottom or parasitic on the shark, offal thrown overboard, or smaller pieces of flesh which are left unnoticed by the shark when it tears its prey. The pilot, therefore, stands to both in the relation of a so-called "commensal," like the *Echeneis* or sucking-fish, whose habits are in some respects identical with those of the pilot, and which is frequently found associated with it. All observers, however, agree that neither the pilot nor the sucker is ever attacked by the shark. The pilot attains to a length of about 12 inches. In the shape of its body it resembles a mackerel, but is rather shorter, especially in the head, and covered with small scales. A sharp keel runs along the middle of each side of the tail. The first dorsal fin consists of a few short spines not connected by a membrane; the second dorsal and the anal are composed of numerous rays. The teeth, which occupy the jaws, vomer, and palatine bones, are all small, in villiform bands. The coloration of the pilot renders it conspicuous at a distance; on a bluish ground-colour from five to seven dark-blue or violet cross-bands traverse the body from the back to the belly. The pilot-fish spawns in the open sea, and its fry is constantly caught in the tow-net. But young pilot-fish differ considerably from the adult, having the spines of the first dorsal connected by a membrane, and some bones of the head armed with projecting spines. These little fishes were therefore long considered to be a distinct genus, *Nauclerus*.

**PILPAY.** See **BIDPAR**, vol. iii. p. 666.

**PILSEN**, the second town of Bohemia, lies at the confluence of the Radbusa and the Mies, 50 miles to the south-west of Prague. It consists of the town proper, which is regularly built and surrounded with promenades on the site of the old ramparts, and of three suburbs. The most prominent buildings are the Gothic church of St Bartholomew, said to date from 1292; the Renaissance town-house, containing an interesting armoury; the new real school; and the German and Bohemian theatres. The staple article of manufacture and commerce is beer, of which about 6,000,000 gallons are brewed here annually. Other industrial products are machinery, enamelled tinware, leather, alum, paper, earthenware, stoves, and spirits, while a tolerably brisk trade is carried on in wool, feathers, cattle, and horses. In the neighbourhood are several coal-pits, iron-works, and glass-works, as well as large deposits of kaolin. The four annual fairs have lost much of their former importance. The population in 1880 was 38,883, consisting of Germans and Czechs in nearly equal proportions.

Pilsen first appears in history in 976, as the scene of a battle between Otto I. and Henry V., duke of Bavaria, and it became a town in 1272. During the Hussite wars it resisted several sieges, but it was taken by Mansfeld in 1618. Wallenstein fixed his headquarters at Pilsen in 1633-34; and it was the principal scene of the alleged conspiracy which cost him his life. The first printing press in Bohemia was set up at Pilsen in 1468.

**PIMENTO**, also called **ALLSPICE** (from a supposed combination of various flavours) and **JAMAICA PEPPER**, is the dried immature fruit of *Eugenia Pimenta* or *Pimenta officinalis*, an evergreen tree about 30 feet high belonging to the natural order *Myrtaceæ*. It is indigenous in the West India Islands, growing on limestone hills near the sea. The spice derives its name from *pimienta*, the Spanish word for pepper, which was given to it by the early explorers of the New World from its resemblance to peppercorns. The allspice of commerce is furnished almost wholly by the island of Jamaica; and all attempts to cultivate the tree where it is not found growing spontaneously have hitherto failed. The so-called pimento walks or natural plantations from which the pimento is collected are formed by cutting down other growth upon land where

the tree grows naturally, and thus allowing it to multiply freely. The berries are gathered in July and August, when of full size, but still unripe,—the small branches bearing fruit being broken off and dried in the sun and air for some days, when the stalks are removed and the berries are ready for packing. These owe their aromatic properties to an essential oil, of which they yield on distillation from 3 to 4½ per cent. This oil has a specific gravity of 1·037, deflects the ray of polarized light 2° to the left when examined in a column of 50 millimetres, and has substantially the same composition as oil of cloves, although differing in flavour. The berries also contain a tannin (giving a black colour with ferric salts), starch, and a minute quantity of an alkaloid which, according to Dragendorff, has somewhat the odour of conia. The chief use of pimento is as a spice. The oil and distilled water are used to a limited extent in medicine to disguise the taste of nauseous drugs, and the oil is also used in perfuming soaps. The yield of some trees is said to reach as much as 150 lb of fresh or 112 lb of dried berries. The highest export reached of late years was 6,857,830 lb in 1870-71, valued at £28,574. In 1877-78 it was 6,195,109 lb. About two-thirds of the produce goes to England, and one-third to the United States. The value in the London market is about 4d. to 6d. per lb.

The fruit of an allied species, *Pimenta acris*, Wight, distinguished by the calyx being crowned with teeth, is sometimes met with in commerce. The bay rum so much used as a toilet article in the United States is a tincture flavoured with the oil of the fruit and leaves of *P. acris*, which is commonly known as the bayberry tree.

**PIN.** A pin is a small spike, usually of metal, with a bulbed head, or some other arrangement for preventing the spike passing entirely through the cloth or other material it is used for fastening together. In one form or another pins are of the highest antiquity, and it may be assumed that their use is coeval with human dress of any kind, the earliest form doubtless being a natural thorn, such as is still often seen fastening the dresses of peasant women in upper Egypt. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. Brooches and pins on which considerable artistic ingenuity was lavished were universally used among the civilized nations of antiquity (see **BROOCH**, vol. iv. p. 369). The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an Act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted, and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. His business flourished so well that he soon gave employment to 1500 persons, and Stroud pins attained a high reputation. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several

pin-making machines were invented in the United States. During the war of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836. Previous to this an American, Mr Lemuel W. Wright of Massachusetts, had in 1824 secured in England a patent for a pin-making machine, which established the industry on its present basis.

The old form of pin, which has become obsolete only within the memory of middle-aged persons, consisted of a shank with a separate head of fine wire twisted round and secured to it. The formation and attachment of this head were the principal points to which inventive ingenuity was directed. The old method of heading involved numerous operations, which had to be expeditiously accomplished, and, notwithstanding the expertness of the workers, the result was frequently unsatisfactory. Fine wire for heads was first wound on a lathe round a spit the exact circumference of the pin shanks to be headed. In this way a long elastic spiral was produced which had next to be cut into heads, each consisting of two complete turns of the spiral. These heads were softened by annealing and made into a heap for the heading boy, whose duty was to thrust a number of shanks into the heap and let as many as might be fit themselves with heads. Such shanks as came out thus headed were passed to the header, who with a falling block and die arrangement compressed together shank and head of such a number as his die-block was fitted for. All the other operations of straightening the wire, cutting, pointing, &c., were separately performed, and these numerous details connected with the production of a common pin were seized on by Adam Smith as one of the most remarkable illustrations of the advantages of the division of labour.

The beautiful automatic machinery by which pins are now made of single pieces of wire is an invention of the present century. In 1817 a communication was made at the Patent Office by Seth Hunt, describing a machine for making pins with "head, shaft, and point in one entire piece." By this machine a suitable length of wire was cut off and held in a die till a globular head was formed on one end by compression, and the other end was pointed by the revolution around it of a roughened steel wheel. This machine does not appear to have come into use; but in 1824 Wright patented the pin-making apparatus above referred to as the parent form of the machinery now employed. An extension for five years, from 1838, of Wright's patent, with certain additions and improvements, was secured by Henry Shuttleworth and Daniel Foote Tayler, and in the hands of Tayler's firm in Birmingham the development of the machine has principally taken place. In a pin-making machine as now used wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficiently wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting points are held against a revolving file-cut steel roller, along the face of which they are carried by gravitation till they fall out at the extremity well-pointed pins. The pins are next purified by boiling in weak beer; and, so cleaned, they are arranged in a copper pan in layers alternating with layers of grained tin. The contents of the pan are covered with water over which a quantity of argol (bitartrate of potash) is sprinkled, and after boiling for several hours the brass pins are coated with a thin deposit of tin, which gives them their silvery appearance. They are then washed in clean water and dried by revolving in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed finished pins.

A large proportion of the pins sold are stuck into paper by an automatic machine not less ingenious than the pin-making machine itself. Mourning pins are made of iron wire, finished by immersing in black japan and drying in a stove. A considerable variety of pins, including the ingeniously coiled, bent, and twisted nursery safety pin, ladies' hair pins, &c., are also made by automatic machinery. The sizes of ordinary pins range from the 34-inch stout blanket pin down to the finest slender gilt pins used by entomologists, 4500 of which weigh about an ounce. A few years ago it was estimated that in the United Kingdom there were made daily 30,000,000 pins, of which 37,000,000 were produced in Birmingham, and the weight of brass and iron wire then annually consumed was stated at 12754 tons, of which one-eighth part was iron wire. The annual value of the whole British trade was stated at £222,000. At the same time the consumption of wire in pin-making in the United States was estimated to be from 350 to 500 tons per annum, the value of the trade being £112,000.

PINDAR, the greatest lyric poet of ancient Greece whose work is represented by large remains, was born

about 522 B.C., being thus some thirty-four years younger than Simonides of Ceos. His father's name was Daiphantus; his birthplace the village of Cynoscephalæ near Thebes in Boeotia. The traditions of his family, which claimed a proud descent, have left their impress on his poetry, and are not without importance for a correct estimate of his relation to his contemporaries. The clan of the Ægeidæ—tracing their line from the hero Ægeus—belonged to the "Cadmean" element of Thebes, i.e., to the elder nobility whose supposed date went back to the days of the founder Cadmus. A branch of the Theban Ægeidæ had been settled in Achaean times at Amyclæ in the valley of the Eurotas (Pind. *Isthm.* vi. 14), and after the Dorian conquest of the Peloponnesus had apparently been adopted by the Spartans into one of the three Dorian tribes. The Spartan Ægeidæ helped to colonize the island of Thera (Pind. *v.* 68). Another branch of the race was settled at Cyrene in Africa; and Pindar tells how his Ægid clansmen at Thebes "showed honour" to Cyrene as often as they kept the festival of the Carneia (Pind. *v.* 75). Pindar is to be conceived, then, as standing within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean" or of Achaean stock. And the wide ramifications of the Ægeidæ throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

Pindar is said to have received his first lessons in flute-playing from one Scopelinus at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his use of Theban mythology, is said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrto, "for that she, a woman, contended with Pindar" (ὄρι βαῖνὰ φοῦτ' ἔβα Πινδάρου ποτ' ἔριν)—a sentiment, it may be remarked, which does not well accord with the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (ὀρχήστικη). Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyrist was required to temper into a harmonious whole (see, e.g., *Ol.* iii. 8, vi. 91, ix. 1, xiv. 15, xiii. 18; *Pyth.* xii. 23, &c.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.). He visited the court of Hiero at Syracuse; Theron, the despot of Agragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god."<sup>1</sup> He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

<sup>1</sup> Πινδάρου γένος, in ed. Ald.: ἐτιμήθη δὲ σφόδρα ὑπὸ πάντων τῶν Ἑλλήνων διὰ τὸ ὑπὸ τοῦ Ἀπόλλωνος οὐτὶ φιλεῖσθαι ὡς καὶ μερῶς τῶν προσφερομένων τῷ θεῷ λαμβάνειν, καὶ τὸν ἱερέα βοᾶν ἐν ταῖς θυσίαις Πινδάρου ἐπὶ τῷ δεῖπνον τοῦ θεοῦ.

Among the Greeks of his own and later times, Pindar was pre-eminently distinguished for his piety towards the gods (εἰσεβήτατος, *ant. vit.*). He tells us that, "near to the vestibule" of his house (παρ' ἐμὸν πρόθυρον, *Pyth.* iii. 77), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the Phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Ægid ancestry, stood "where Zeus Ammon hath his seat," i.e., near the oasis and temple (Διὸς ἐν Ἀμμωνος θεμίστοις, *Pyth.* iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedæmonians was burning Thebes, some one wrote on Pindar's house, 'Burn not the house of Pindar the poet;' and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention.<sup>1</sup> Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private ξοῖα with Philip or Alexander, or by public ξοῖα with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (ii. 33, 25), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I. of Macedon. But he must have been also, or chiefly, induced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.<sup>2</sup> Upwards of six hundred years after Pindar's death, the traveller Pausanias saw an iron chair which was preserved among the most precious treasures of the temple in the sanctuary at Delphi. It was the chair, he was told, "in which Pindar used to sit, whenever he came to Delphi, and to chant those of his songs which pertain to Apollo."

During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Æschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (παῖδες Ἀθηναίων ἐβάλοντο

φαινήν κρητὸν ἐλευθερίας, fr. 77, Bergk, 4th ed.), while Athens itself is thus invoked:—ὦ τὰι λιπαραὶ καὶ ἰσοτέφανοι καὶ ἀοιδμοί, Ἑλλάδος ἔρεισμα, κλειαὶ Ἀθῆναι, δαιμόνιον πολίεθρον. Isocrates, writing in 353 B.C., states that the phrase Ἑλλάδος ἔρεισμα, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of προξενία (i.e., appointed him honorary consul, as it were, for Athens at Thebes), besides presenting him with a large sum of money (*Antid.* § 166). One of the letters of the pseudo-Æschines (*Ep.* iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum.<sup>3</sup> The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (i. 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth.* i. 75). In celebrating the Pythian victory of the Athenian Megacles, he begins thus:—"Fairest of preludes is the renown of Athens for the mighty race of the Alcæonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear!" Referring to the fact that an Æginetan victor in the games had been trained by an Athenian, he says—χρὴ δ' αἶψ' Ἀθῆναι τέκτον' ἀθληταῖσιν ἔμμεν (*Nem.* v. 49); "meet it is that a shaper of athletes should come from Athens"—where, recollecting how often Pindar compares the poet's efforts to the athlete's, we may well believe that he was thinking of his own early training at Athens under Lasus of Hermione.

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Carm.* iv. 2); and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

1. *Ἕμνοι*, Hymns to deities—as to Zeus Ammon, to Persephone, Fragment to Fortune. The fragmentary ἕμνος entitled Θηβαίος seems to mention the deities of Thebes. 2. *Παιᾶνες*, *Pæans*, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis, or Zeus. 3. *Διθύραμβοι*, *Dithyrambs*, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus (cp. *Pind.*, *Ol.* xiii. 18, τὰ Διωνύσου πόθεν ἐξέφαιεν σὺν βοηλάτῃ Χάρμης διθύραμβος, where Pindar alludes to the choral form given to the dithyramb, c. 600 B.C., by Arion, —βοηλάτης, "ox-driving," perhaps meaning "winning an ox as prize"). 4. *Προσόδια*, *ProceSSIONAL Songs*, choral chants for worshippers approaching a shrine. One was written by Pindar for the Delians, another for the Æginetans. 5. *Παρθένια*, *Choral Songs for Maidens*. The reference in *Pind.* *Pyth.* iii. 77 to maidens worshipping Cybele and Pan near the poet's house is illustrated by the fact that one of these Παρθένια invoked "Pan, lord of Arcadia, attendant of the Great Mother, watcher of her awful shrine" (fr. 95, Bergk). 6. *Ἰσορχήματα*, *Choral Dance-Songs*, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (107), written for the Thebans in connexion with propitiatory rites after an eclipse of the sun, probably that of April 30, 463 B.C. 7. *Ἑγκώμια*, *Songs of Praise* (for men, while ἕμνοι were for gods), to be sung by a κύμας, or festal company. In strictness ἐγκώμιον was the genus of which ἐπὶνίκιον was a species; but the latter is more conveniently treated as a distinct kind. Pindar wrote encomia for Theron, despot of Agragras, and for Alexander I. (son of Amyntas), king of Macedon. 8. *Σκόλια*, *Festal Songs*. The

<sup>1</sup> Schaefer, *Demosthenes und seine Zeit*, iii. 119.

<sup>2</sup> It will be remarked that history requires us to modify the statement in Milton's famous lines:—

"The great Emathian conqueror took spare  
The house of Pindarus, when temple and tower  
Went to the ground."

Indeed, the point of the incident depends much on the fact that the temples and Pindar's house were classed together for exemption.

<sup>3</sup> Compare Jebb, *Attic Orators*, vol. ii. p. 143.

usual sense of σκόλιον is a drinking-song, taken up by one guest after another at a banquet. But Pindar's σκόλια were choral and antistrophic. One was to be sung at Corinth by a chorus of the ιερῶδονοι attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character. 9. Θρήνοι, Dirges, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class (129-133). One of the smaller fragments (137)—in memory of an Athenian who had been initiated into the Eleusinian mysteries (ἰδὼν κείνα)—has been conjecturally referred to the Θρήνοι which Pindar is said to have written (schol. *Pyth.* vii. 18) for Hippocrates, the grandfather of Pericles. A number of small fragments, which cannot be certainly classified, are usually given as ἐξ ἀδήλων εἰδῶν, "of uncertain class." On comparing the above list with Horace, *Carm.* iv. 2, it will be seen that he alludes to No. 3 (*dithyrambos*); to Nos. 1, 2, and 7 (*sens deus regesve canit*); and to No. 9 (*flebitis sponsas juvenemve raptum Plorat*),—as well as to the extant *Epinicia* (*sive quos Elea domum reducit Palma caelestes*).

The  
extant  
odes.

The *Epinicia*.—The ἐπινίκια (sc. μέλη), or ἐπινίκιοι (sc. ὕμνοι), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals:—(1) Ὀλυμπιονίκαι (sc. ὕμνοι): fourteen odes for winners of the wild olive-wreath in the Olympian games, held at Olympia in honour of Zeus once in four years; (2) Πυθιονίκαι: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) Νεμεονίκαι: seven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) Ἰσθμιονίκαι: eleven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. plur. followed by the numeral, e.g., "the ninth Olympian" is Ὀλυμπιονίκαι θ'. The chronological range of the collection (so far as ascertainable) is from 502 B.C. (*Pyth.* x.) to 452 B.C. (*Ol.* v.). With respect to the native places of the victors, the geographical distribution is as follows:—for the mainland of Greece proper, 13 odes; for Ægina, 11; for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

The general characteristics of the odes may be briefly considered under the following heads:—(1) language; (2) treatment of theme; (3) sentiment—religious, moral, and political; (4) relation to contemporary art.

Language.

1. The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness. Thus (a) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called εἰδιανὸν φάρμακον αἰσῶν (*Ol.* ix. 104), "a warm remedy for winds." (b) Images for the highest excellence are drawn from the furthest limits of travel or navigation, or from the fairest of natural objects; as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (*Isthm.* ii. 42); or when Olympia, the "crown" (κορυφαία) or flower (ἄστρος) of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (*Ol.* i. ad init.). This trait might be called the *Pindaric imagery of the superlative*. (c) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (*Pyth.* v. 56). (d) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone,

mixing wine in a bowl, and many more. (e) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the σκυτάλη or secret despatch, &c. And we have such homely proverbs as, "he hath his foot in this shoe," i.e., stands in this case (*Ol.* vi. 8). (f) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (g) Words not found except in Pindar are numerous, many of these being compounds which (like ἐναρίμβροτος, καταφυλλοραεῖν, &c.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "bold dithyrambs."

2. The actual victory which gave occasion for the ode is seldom treated at length or in detail,—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arceas, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes,—(as the birth of Iamus (*Ol.* vi), or the vision of Bellerophon (*Ol.* xiii),—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn, καὶ τῶν ὀλμων ἱσάμι βραχύν (*Pyth.* iv. 247). It has been thought that, in the parenthesis about the Amazons' shields (*quibus Mos unde deductus . . . quarere distuli*, *Carm.* iv. 4, 17), Horace was imitating a Pindaric transition; if so, he has illustrated his own observation as to the peril of imitating the Theban poet.

3. (a) The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they dined with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz., that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as *Ol.* ii. 66 sq.). Pindar was familiar with the idea of metempsychosis (cp. *ib.* 83), but the attempt to trace Pythagoreanism in some phrases (*Pyth.* ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the Θρήνος (no. 137, Bergk), we may probably regard the mystic or esoteric element in Pindar's theology as due to such a source.

(b) The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (φύσις) is the grand source of all human excellence (ἀρετή), while such excellences as can be acquired by

Sentiment  
of the odes  
—re-  
ligious;

study (*ἐὺδακταὶ ἀρεταί*, *Ol.* ix. 106) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of *εὖχαιος ὄλβος*—"sane happiness," such as has least reason to dread the jealousy of the gods, —are substance sufficing for daily wants and good repute (*αἰδορέα*). He who has these should not "seek to be a god." "Wealth set with virtues" (*πλοῦτος ἀρεταῖς δεδαυμένους*), as gold with precious gems, is the most fortunate lot, because it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (cp. *Pyth.* ii. 83; *Isthm.* iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

(c) The political sentiments of the Theban poet are suggested by *Pyth.* xi. 53; "In politics I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in *Pyth.* ii. 86 a democracy is described as *ὁ λαβρός στρατός*, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of these democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (*δημοκρατία ἰσοκρατία*, *Thuc.* iii. 62) had replaced the narrower and less temperate oligarchy of former days (*ἐπιτοκία αὐτὰ μετὰ νόμους*); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol.* i. 113); he sketches the character of an ideal king (*Pyth.* iii. 71); but nothing in his poetry implies liking for the *πρωτεύς* as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours "Tranquillity, the friend of cities" (*Ἀσυχία φιλόπολις*, *Ol.* iv. 16). The epic poet sang of wars; Pindar celebrates the "rivalries of peace."

4. Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (*τόλμα δὲ καὶ ἀμφελαρήν δόξαμιν ἔπεισοι*, *Ol.* ix. 80). Here we see the exulting sense of inward strength; in many other places we perceive the feeling of conscious art—as in the phrase *καυτάλλων*, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the Hours is opened, and delicate plants perceive the fragrant spring" (fr. 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 194); in the lines on the eclipse of the sun (fr. 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable, —as in the beautiful story of the birth of Iamus—when

Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

The spirit of art, in every form, is represented for Pindar by *χάρις*—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The Sculpture period from 500 to 460 B.C., to which most of Pindar's extant odes belong, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon, and Ægina were effecting a transition from archaic types to the art which was afterwards matured in the age of Phidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards, sculpture had been applied to the commemoration of athletes, chiefly at Olympia. In a striking passage (*Nem.* v. ad init.) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Ægina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Ægina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithæ, and (6) a contest between Heracles and Apollo are instances of mythical material treated alike by the poet and by sculptors of his day. The contemporary improvements in town architecture, introducing spacious and well-paved streets, such as the *σκιερὴ δόξ* at Cyrene (*Pyth.* v. 87), suggest his frequent comparison of the paths of song to broad and stately causeways (*πλαταῖα πρόσδοι—ἐκατόμπεδοι κέλευθοι*, *Nem.* vi. 47, v. 22). A song is likened to cunning work which blends gold, ivory, and coral (*Nem.* vii. 78). Pindar's feeling that poetry, though essentially a divine gift, has a technical side (*σοφία*), and that on this side it has had an historical development like that of other arts, is forcibly illustrated by his reference to the inventions (*σοφίσματα*) for which Corinth had early been famous. He instances (1) the development of the dithyramb, (2) certain improvements in the harnessing and driving of horses, and (3) the addition of the pediment to temples (*Ol.* xiii.).

In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alceus and Sappho write for Lesbians, Aleman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker*. The Greeks usually spoke, not of "lyric," but of "melic" poetry (i.e., meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyricist. Epic, lyric, and dramatic poetry succeeded each other in Greek litera-

ture by a natural development. Each of them was the spontaneous utterance of the age which brought it forth. In Pindar we can see that phase of the Greek mind which produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Æschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

Manu-  
scripts  
and  
editions.  
The fact that certain glosses and lacunæ are common to all our MSS. of Pindar make it probable that these MSS. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (circ. 15 B.C.), sometimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (160 A.D.). The archetype of our MSS., then, cannot have been older than the end of the 2d century. Our MSS. fall into two general classes:—(1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.-xii.; Mediceus 2; and Vaticanus 2,—the two last-named being of the highest value. The *editio princeps* is the Aldine, Venice, 1513. A modern study of Pindar may be almost said to have begun with Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But Augustus Boeckh (1811-22), who was assisted in the commentary by L. Disen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poet. Lyr.*) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to MSS. A recension by W. Christ has been published in Teubner's series (1879). The edition of J. W. Donaldson (Cambridge, 1841) has many merits; but that of C. A. M. Fennell (Cambridge, 1879-83) is better adapted to the needs of English students. The translation into English prose by Ernest Myers (2d ed., 1883) is excellent. Pindar's metres have been analysed by J. H. Schmidt in *Die Kunstformen der Griechischen Poesie* (Leipzig, 1868-72). For estimates of Pindar see the histories of Greek literature by G. Bernhardt, K. O. Müller, Nicolai, and E. Burnouf. (R. C. J.)

PINE (*Pinus*, Gr. *πίκνυς*), a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus of true conifers (*Abietinæ*), differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membranous sheath, either in pairs or from three to five together,—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature—as in the allied genera.

The pines are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which, in Central America, a few are found within the tropic; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. Their soft, straight-grained,

resinous, and often durable wood gives to many kinds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris*, the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 feet, it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top, with a straight trunk of from 2 to 4 feet in diameter at the base, and gnarled twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often

FIG. 1.—Scotch Fir (*Pinus sylvestris*). a, male flower and young cones; b, male catkin; c, d, outer and inner side of anther-scale.

twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and fecundate the purple female flowers, which, at first sessile and erect, then become recurved on a lengthening stalk; the ovate cones, about the length of the leaves, do not reach maturity until the autumn of the following year, and the seeds are seldom scattered until recurved point, well-marked in the green state and in some varieties in the mature cone, but in others scarcely projecting. *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest-slopes of Etna, while in longitude its range extends from the shores of the North Sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula, this tree is the true fir (*fur*, *fura*) of the old Norsemen, and still re-

tains the name among their descendants in Britain, though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground, and is found even at an elevation of 700 feet, while in south Norway it occurs up to 3000 feet, though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the south-eastern dales; in the highest situations it dwindles to a mere bush. In Germany, both on the mountains and the sandy plains, woods of "kiefer" are frequent and widely spread, while vast forests in Russia and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of Dahuria; on the European Alps it occurs at a height of 5600 feet, and on the Pyrenees it is found at still higher elevations; on the northern side of Etna it is

FIG. 2.—Scotch Fir (*Pinus sylvestris*). *a*, fertile flower of mature cone; *b*, winged seed; *c*, fertile catkin (or cone); *d*, scale and bract; *e*, inner side of scale.

said to grow at above 7000 feet. In Britain natural forests of Scotch fir of any extent are only now found in the Highlands, chiefly on the declivities of the Grampians, and most of the great woods have been much curtailed in recent times, while the larger trees are generally felled as soon as they attain a timber size. In former ages the tree covered a large portion of the more northern part of the island, as well as of Ireland; the numerous trunks found everywhere in the mosses and peat-bogs of the northern counties of England attest its abundance there in prehistoric times; and in the remoter post-Glacial epoch its range was probably vastly more extended. The tree is not at present indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus formed during the last fifty years. The Scotch fir is a very

variable tree, and certain varieties have acquired a higher reputation for the qualities of their timber than others; among those most prized by foresters is the one called the Braemar pine, the remaining fragments of the great wood in the Braemar district being chiefly composed of this kind; it is mainly distinguished by its shorter and more glaucous leaves and ovoid cones with blunt recurved spines, and especially by the early horizontal growth of its ultimately drooping boughs; of all varieties this is the most picturesque. On the Continent the Hagenau pine of Westphalia is esteemed for the straightness and good quality of its timber. The heart-wood of the finer kinds of Scotch fir is of a deep brownish-red colour, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps little inferior; from its lightness and elasticity it is well adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb the cubic foot. The sap-wood is more perishable, but is useful for fences, casks, and a variety of other purposes; soaking in lime-water renders it more lasting; great numbers of young pines are annually cut for railway sleepers, mining timber, and numerous agricultural applications; large quantities are consumed in forming the wood-pavement which in the great towns is rapidly superseding stone. The quality of the timber depends greatly on the soil and position in which the trees are grown: the dry slopes of granitic or gneissic mountains, or the deep well-drained sandy gravels of the lower country seem to answer equally well; but on clay or wet peat the tree rarely flourishes, and the timber is always indifferent; it is usually said that the wood is best in the cold climate of its more northern habitats, but the writer has seen a trunk (4 feet in diameter) grown on the sands of Surrey with heart-wood quite equal to any produced in Glenmore or Rothiemurchus. The rapidity of growth is still more variable: in Britain full maturity is attained in from seventy to one hundred and twenty years, but in Norway the trunk increases much more slowly; Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 feet 10 inches in diameter without the bark, showed four hundred circles of annual growth. In Norway the tree, growing in dense forests, is generally of but moderate girth, and probably this pine nowhere reaches a greater size than in the Scottish woods; a plank from Glenmore forest measured nearly 5½ feet across, and from 3 to 4½ feet is not an unusual diameter for a British pine tree.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct from the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of Scotch fir requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, excepting for the removal of dead wood. Plantations in England are generally ready for final cutting in from sixty to seventy years, and many are cleared at a much earlier stage of growth. *P. sylvestris* in Britain is liable to many insect depredations: the pine-chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; *Hylobius abietis*, the fir-weevil, eats away the bark, and numerous lepidopterous larvæ devour the leaves; the pine-sawfly is also injurious in some seasons; the removal of all dead branches from the trees and from the ground beneath them is recommended as most of these

insects lay their eggs among the decaying bark and dead leaves. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species. As fuel the wood of the Scotch fir is of value, but it makes too much black smoke to form an agreeable open fire; the small trunks and cuttings of plantations are employed by the lime-burner.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks, and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. Pumilio*, the "krumholz" or "knieholz" of the Germans,—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser, and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tyrolean Alps, it is a favourite shelter for the chamois; the hunters call it the "latsehe," from its recumbent straggling habit. Krumholz oil, valued in Germany as an outward application in rheumatism and for bruises and sprains, is distilled from the young branches, and a fragrant white resin that exudes in some quantity from the buds is used for similar purposes and as a perfume; under the name of Hungarian balsam it is sold in the towns of Germany, being probably obtained from the Carpathians.

The Red Pine of Canada and New England (so called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 inches long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in shipbuilding; according to Emerson, trunks exist in Maine 4 feet in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the Grey or Labrador Pine, some-

times called the Scrub Pine from its dwarfish habit; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 inches long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

*P. Laricio*, the Corsican Pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 feet, with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 inches long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The Black Pine, *P. austriaca*, derives its name from the extreme depth of its foliage tints,—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree. The light-coloured, glossy, horizontal cones are generally in pairs; but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain. The leaves are long and of a light bright green; the cones are solitary, oblong, conical, and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality. In plantations its bright foliage, with the orange cones and young shoots, render it an ornamental tree, hardy in southern Britain. Near to the above are *P. Pallasiana* or *maritima*, and *P. halepensis*, Mediterranean forms chiefly valued for their resinous products; the former, planted on the loose sands of France, supplies much turpentine and resin.

*P. Pinaster*, the Cluster Pine or Pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 70 feet, the deeply-furrowed trunk occasionally reaches a diameter of 3 feet or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 inches long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions. *P. brutia*, the Calabrian Pine, a kindred cones; its wood is considered good in southern Italy.

*P. Pinca* is the Stone-Pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful

reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 feet in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

*P. mitis*, the Yellow Pine of the northern and middle States of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 feet and upwards, though rarely more than 2 feet in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ inches long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in shipbuilding and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the Pitch-Pine of the northern States, a tree of from 40 to 50 feet in height with rugged trunk, occasionally 3 feet in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

*P. australis* is the "Georgia Pitch-Pine," or Yellow Pine of the southern States; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence it is sometimes called *P. palustris*. The most marked feature of the tree is its long tufted foliage,—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the States; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West India Islands. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

*P. taeda*, the "Loblolly Pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern States, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 feet high, having sometimes a girth of 6 or 8 feet, with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

*P. ponderosa*, a pine of western America belonging to this section, is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri*, or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 inches in diameter, and weighing more than 4 lb); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiana*, the Nut-Pine of California, the cones of which are of nearly equal size, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 feet and upwards, while trunks have been found, it is said, 10 or 12 feet in diameter. *P. longifolia*, a Nepal species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "Cheer-

Pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, another Nepal species, is a large tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer-pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Tenerife, growing at an elevation of 6000 feet, also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey-Pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three or four; the lower cone-scales have recurved points. This fine pine has been planted in the south-western parts of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known White Pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of American trees. The tree abounds from Canada to Georgia, and is also found in British Columbia, but in the eastern States has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England; one that stood near the banks of the Merrimaek in New Hampshire is said to have had a trunk nearly 8 feet in diameter, and Michaux measured a stump 6 feet across. On a deep rich soil *P. Strobus* attains a height of 150 or even 200 feet, and trunks without a branch are sometimes found 80 or 90 feet long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 inches in length and 1½ to 2 inches broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 lb per cubic foot. In England, where it is generally known as the "Weymouth Pine," it succeeds well on deep light soils when well-drained; trees have attained occasionally a height of 100 feet and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well; a tree at Berlin measured upwards of 3 metres in circumference, the age being one hundred and fifty years. The climate of Scotland appears less suitable for it, probably from the want of summer heat, and it can hardly be recommended for British planting otherwise than for ornamental purposes.

Nearly approaching this is *P. excelsa*, the Bhotan Pine, which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhotan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 6000 to 7000 feet, and attains large dimensions; the wood is highly resinous, and is said to be durable; great quantities of a white clear turpentine exude from the branches when injured. The Bhotan pine is quite hardy in southern England, and has been largely planted of late as an ornamental tree.

*P. Lambertiana*, the Giant Pine or Sugar-Pine of California, is the largest of the genus, rising to the height of 200 feet, with a trunk 20 to 30 feet in girth, and, it is said, occasionally attaining much larger dimensions. The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce; its foliage is of a light bright green colour. The pendant cones are very large, sometimes 18 inches long and 4 inches in diameter, with large nut-like seeds, which, pounded and baked, are eaten by the Indians. The tree abounds in some sandy districts, but more generally occurs singly or in small groups dispersed through the woods, attaining its greatest dimensions in light soils. The wood is soft and nearly white, but contains much resin, which when fire has run through the forest exudes, and, having in this half-burnt condition a sweetish taste, has given the common name to the tree; the wood seems to be formed slowly; from its smooth grain it is valued for indoor carpentry; the saccharine burnt resin is used as a laxative in California.

*P. Cembra* is the Stone-Pine of Siberia and central Europe. It abounds on the Alps, the Carpathians, and the Siberian ranges, in Switzerland being found at an altitude of 6800 feet in some localities. It is a straight-growing tree, with grey bark and whorls of horizontal branches, growing often from the ground, giving a

cylindro-conical outline; the leaves are short, rigid, and glaucous; the cones, oblong and rather pointing upwards, grow only near the top of the tree, and ripen in the second autumn; the seeds are oily like those of *P. Pinus*, and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed from them which is used both for food and in lamps, but, like that of the Italian pine, it soon turns rancid. The growth of *P. Cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood-carvers in preference to any other. The *Cembra* is the "zirbel" or "zirbel-kiefer" of the Germans, and is known locally in Switzerland as the "aroile," "aloies," and "arve."

*P. occidentalis*, a five-leaved pine with pale green foliage and small ovate cones, is found on the high mountains of St Domingo. Many members of the group occur on the Mexican isthmus, one of which, *P. cembroides*, produces edible seeds. *P. Ayacahuite*, a large tree growing on the mountains of Guatemala, with glaucous foliage like *P. Strobus*, yields a valuable resin. *P. jilifolia* and *P. macrophylla*, likewise natives of Central America, are remarkable for the extreme length of their leaves; the former is said to attain a large size.

(C. P. J.)  
**PINE-APPLE.** The pine-apple so-called consists in reality of the inflorescence of the plant, the originally separate flowers of which, together with the bracts supporting them, become fleshy and consolidated into one mass. The swelling and fusion of the tissues take place after the process of fertilization, and it may be that the richly perfumed succulent mass is an aid in the distribution of seed by affording food to certain animals. In the highly developed cultivated pines, however, it frequently happens that the seeds do not ripen properly. The pine, *Ananassa sativa*, is a member of the Bromeliad family, supposed to be of tropical American origin, and has been found wild in Mexico, Central America, Guiana, and Brazil, but is now widely dispersed in all tropical and semitropical countries.

Evelyn in his *Diary* mentions tasting a pine-apple from Barbados at the table of Charles II., and this is we believe the first mention of the fruit in English literature. A picture, of which a copy may be seen at the rooms of the Royal Horticultural Society of London, represents the royal gardener, Mr Rose, presenting on bended knee the first pine-apple grown in Britain, and it is surmised that this may have been grown from the "suckers" of the fruit above alluded to by Evelyn, though it is generally considered that the pine was not cultivated in England till 1712. In spite of the great improvements in the quality of pines, and the great progress that has been brought about in the rapidity and facility of production, pine-growing is still attended with considerable expense, and much expenditure of time and labour. At the same time great attention has been given to pine culture in the West India Islands, the Azores, &c., and very large quantities of fruit of fine quality are imported into Britain at relatively low prices. But for pines of the highest flavour in the winter and spring seasons Englishmen must still look to their own gardens. See **HORTICULTURE**.

**PINEL, PHILIPPE** (1745-1826), a distinguished French physician, was born at the chateau of Rascas, Saint-André, in the department of Tarn, France, on April 20, 1745. He studied at Lavaur and afterwards at the university of Toulouse, where he took his doctor's degree in 1773. From Montpellier, where he taught mathematics and at the same time carried on his medical studies, he removed in 1778 to Paris, engaging there chiefly in literary work connected with his profession. His first publication was a French translation of Cullen's *Nosology* (1785); it was followed by an edition of the works of Baglivi (1788), and in 1791 he published a *Traité medico-philosophique de l'aliénation mentale*. In 1792 he became head physician of the Bicêtre, and two years afterwards he received the corresponding appointment at the Salpêtrière, where he began to deliver a course of clinical lectures; these formed the basis of his *Nosographie philosophique* (1798; 6th ed. 1818), which was further developed in *La Médecine*

*clinique* (1802). Pinel was made a member of the Institute in 1803, and soon afterwards was appointed professor of pathology in the École de Médecine. Neither as a lecturer nor as an author, however, did he achieve great success, and his enduring fame rests entirely upon the fact that by his courageous action he was among the first to introduce the humane treatment of the insane, removing with his own hands the bonds of patients who had been chained to the wall for years. See vol. xiii. p. 110. He died at Paris on October 26, 1826.

**PINEROLO**, a city of Italy, in the province of Turin (Piedmont), is built in a straggling manner on a hill-side just above the junction of the valleys of the Chisone and the Lemina, at a height of 1237 feet above the sea, 23½ miles by rail south-west of Turin. It is the terminus of the branch railway from Turin by Sangone or Nichellino, and has steam tramways running up to Perosa (12 miles) and south to Saluzzo. Till 1696 it was strongly fortified with a citadel on Santa Brigida, a castle on St Maurizio, and city walls constructed by Thomas I. of Savoy. It has a cathedral (St Donatus), a bishop's palace, a large seminary, a theatre (1842), a hospital (1546), a public library, a cavalry college, a school of music, and a Waldensian chapel and schools. Cotton, silk, wool, and hemp are among the local manufactures. The population of the city was 11,362 in 1871 and 12,003 in 1881 (commune 16,730 and 17,492).

Pinerolo was bestowed on the bishops of Turin by Otho III. in 996; but in 1078 the countess Adelaide made it over to the Benedictine abbey of Santa Maria, in whose possession it remained till 1159. Thomas I. of Savoy captured the castle in 1183, and in 1246 the commune formally recognized the supremacy of Savoy. Passing in 1295 into the hands of Philip, son of Thomas III., Pinerolo became his residence and capital, a distinction which it retained under Amadeus VIII. of Savoy, even after the extinction of the separate house of Piedmont in 1418. Francis I. of France obtained possession of the town in his descent into Italy, and tried to secure the allegiance of the people by relieving the woollen trade from taxation; but Emmanuel Philibert received it back from Henry III. in 1574. A second occupation by the French occurred under Cardinal Richelieu: the French language was imposed on the people, great fortifications were constructed, and the fortress was used as a state prison for such men as Fouquet, De Caumont, and the Man with the Iron Mask. Victor Amadeus bombarded the place in 1693, and ultimately compelled Louis XIV. to relinquish his hold on it; but before the withdrawal of the French troops the defences were demolished and the military importance of Pinerolo brought to a close. In 1748 the town was made a bishop's see. Michele Buniva, pensioned by Victor Emmanuel I. as the introducer of vaccination into Piedmont, was a native of Pinerolo and has a statue in the Piazza del Palazzo. De Grossi and Massi are among the local historians.

**PINK.** As usually applied this word corresponds to a genus of *Caryophyllaceæ*, the *Dianthus* of botanists. It is characterized by the presence of opposite simple leaves proceeding from thickened nodes, a cymose inflorescence, a tubular calyx surrounded by a number of overlapping bracts, a showy corolla of five free long-stalked petals, ten stamens proceeding, together with the petals, from a short stalk supporting the ovary, which latter has two styles and ripens into an oblong pod which splits by two valves. The species are herbaceous or perennial, of low stature, often with very showy flowers. They are natives chiefly of southern Europe and the Mediterranean region, a few being found in temperate Asia and South Africa. One species only is native to America, and that only in the north-west. Four species are wild in Britain, with two others which are more or less naturalized. These two are the more interesting as being the originals of the pinks and of the carnations and picotees of English gardens. Garden Pinks are derivatives from *Dianthus plumarius*, a native of central Europe, with leaves rough at the edges, and with rose-coloured or purplish flowers. The use of "pink" to denote a colour is derived from the name of the plant.

The Carnation and Picotee are modifications of *Dianthus Caryophyllus*, the Clove Pink, a species with smooth edges to the leaf. This is a native of Europe, growing on rocks in the south, but in the north usually found on old walls. Its occurrence in England on some of the old Norman castles, as at Rochester, is supposed by Canon Ellacombe to indicate its introduction by the Normans; in any case the plant grows in similar situations in Normandy. The original species has "self"-coloured flowers, that is, flowers of one hue, generally some shade of pink, but the variations in gardens are infinite. The carnation includes those flowers which are streaked or striped lengthwise—the picotees are those in which the petals have a narrow band of colour along the edge, the remainder of the petal being free from stripes or blotches. These by the old writers were called "gillyflowers" (see vol. x. p. 601). The Sweet William of gardens is a product from *Dianthus barbatus*; the Indian Pink comes from *D. sinensis*, of which *D. Hedderigii* is a variety; the Alpine Pink, *D. alpinus*, is a very lovely plant for the rockery; and there are many hybrid and other varieties met with in gardens, for an account of which reference must be made to treatises on horticulture.

PINKERTON, JOHN (1758–1826), archaeologist, numismatist, historian, geographer, and miscellaneous writer in prose and verse, was born at Edinburgh, February 17, 1758. After a brief education at Lanark he was articled as a law clerk in Edinburgh, his earliest work, printed during his clerkship, being an *Elegy on Craigmillar Castle* (1776). In 1780 he removed to London to devote himself to literary work, publishing in 1781 a volume of *Rimes* of no great merit, and a professed collection of *Scottish Tragic Ballads*. These were followed in 1782 by *Two Dithyrambic Odes on Enthusiasm and Laughter*, and by a series of *Tales in Verse*. Under the title of *Select Scottish Ballads* he reissued in 1783 his tragic ballads, with a supplement comprising *Ballads of the Comic Kind*,—a collection which obtained for him the not wholly appropriate title of "the second Chatterton." An *Essay on Medals* in 1784 won him a considerable reputation, which was in some respects unpleasantly maintained by his bold but eccentric *Letters on Literature* published in 1785 under the pseudonym of Robert Heron—a temporary adoption of his mother's surname. In the following year he edited the *Ancient Scottish Poems from the MS. Collections of Sir Richard Maitland of Lethington*,—a genuine reproduction, though his confession in the preface of forgery in the previous collections published by him brought groundless suspicion upon it. It was succeeded in 1787 by a compilation, under the new pseudonym of Bennet, entitled the *Treasury of Wit*, and by his first important historical work, the *Dissertation on the Origin and Progress of the Scythians or Goths*, to which Gibbon professed himself indebted. Turning his attention to hagiology, Pinkerton next collected and printed in 1789 certain *Vitz Sanctorum Scotiæ*, and, a little later, published his *Enquiry into the History of Scotland preceding the Reign of Malcolm III.*, in which he hoped to settle the ancient history of his country on the solid footing of facts and authorities and "leave nothing in the ink horn." In many quarters his attitude towards the Highlanders excited "violent disgust," but the *Enquiry* was twice reprinted, in 1794 and 1814, and is still of value for the documents embodied in it. His edition of Barbour's *Bruce* and a *Medallie History of England to the Revolution* appeared in 1790; a collection of *Scottish Poems reprinted from scarce Editions* in 1792; and a series of biographical sketches, the *Iconographia Scotica*, in the years 1795–97. In the last-mentioned year he published a *History of Scotland from the Accession of the House of Stuart to that*

*of Mary*, containing valuable material, but almost entirely devoid of literary finish. A new biographical collection, the *Gallery of Eminent Persons of Scotland* (1799), was succeeded after a short interval by a *Modern Geography digested on a New Plan* (1802; enlarged, 1807). About this time he left London for Paris, where he chiefly resided until his death on May 10, 1826. His remaining publications were the *Recollections of Paris in the years 1802–3–4–5* (1806); a very useful *General Collection of Voyages and Travels* (1808–1813); a *New Modern Atlas* (1809–15); and his *Petrulogy* (1811). An unsuccessful tragedy by him was performed at Edinburgh in 1813.

Pinkerton possessed an exceedingly vigorous and acute mind, but very lacking in high constructive power; and, as he was less patient in the formation of opinion than in research, his best work is marred by imperfect judgments crudely and obstinately asserted. At the same time his writings take no mean rank in the advance towards a scientific treatment of history. Walpole, notes of whose conversations were published at his death by Pinkerton under the title of *Walpoliana*, regarded his understanding as "one of the strongest, most manly, and clearest he ever knew;" and Gibbon not only praised his faculty of persistent application as herculean and heroic, but wished to secure his co-operation in a scheme for organizing the materials of early English history. The final verdict upon his work must be that of the Earl of Buchan, who endorsed Pinkerton's statement that he was "a *homo umbratilis*, of a hypochondriac unsocial disposition," with the comment "*se ipse dixit*: it is his best apology; yet undoubtedly he has been a benefactor to literature."

PINSK, a district town of the government of Minsk, Russia, is situated in a marshy region at the confluence of the Strumen and Pina rivers, 172 miles to the south-west of Minsk. It has a lyceum, several primary schools, and a great number of Jewish schools. The town is almost entirely built of wood, and has a poor appearance. The population (13,000 in 1865) was in 1884 22,950, more than four-fifths of whom are Jews, who live almost exclusively on trade. This development of trade in a town situated at a distance from all railways (the nearest, that from Moscow to Warsaw, being 60 miles off) is due to the navigable river Pina, which connects it with the fertile regions on the Dnieper, and, by means of the Dnieper-and-Bug Canal, with Poland and Prussia, while the canal of Oginsky connects it with the basin of the Niemen. The merchandise brought from the Dnieper is unshipped at Pinsk, and sent west or north-west on smaller vessels.

Pinsk (Pinesk) is first mentioned in Russian annals in 1097 as a town belonging to Sviatopolk, prince of Kieff. In 1132 it formed part of the Minsk principality, and it often changed its rulers subsequently. After the Mongol invasion it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was recognized as chief town of the province of Brest. During the rebellion of Bogdan Khmeluitzky (1640), as it had fallen into the hands of the Cossacks, the Poles took it by assault, destroying 14,000 persons and burning 5000 houses. Eight years later the town was burned again by the Russians. Charles XII. took it in 1706, and when compelled to quit, burned the palace of Prince Wiszniewski, and the town with its suburbs. Pinsk was annexed to Russia in 1795.

PINTO, FERNÃO MENDES (1509(?)–1583), a noted Portuguese adventurer, was born in 1509 or 1510 at Montemor-o-Velho, near Coimbra, and died near Lisbon, July 18, 1583. After spending some years in Lisbon and Setubal, and experiencing various adventures, he left his native country in 1537, in a fleet of five ships, committing himself to a career of adventure at sea, which lasted twenty-one years, in the course of which he was five times shipwrecked, thirteen times taken captive, and seventeen times sold as a slave. If Pinto's own narrative is coloured in many passages by a wandering and fervid imagination, its substantial honesty is now generally admitted, in spite of Congreve's opprobrium in *Love for Love*,—"F. M. Pinto was but a type of thee, thou liar of the first magnitude." The fleet with which Pinto left

Portugal anchored, after various adventures, at Socotra, and he himself was taken captive near the Straits of Babelmandeb, carried to Mocha, sold as a slave, and ransomed by the Portuguese governor of Ormuz. Returning to the Indies, he was again engaged in several expeditions, again enslaved, again ransomed, and again captured by pirates. In 1542 he was engaged in an expedition to Calempin, near Peking, to rifle the tombs of seventeen Chinese kings. Shipwrecked and captured on the Chinese coast, he was set to work in repairing the Great Wall, whence an inroad of Tartars transported him to the siege of Peking and next to Tartary. Hence we follow him to Cochin-China, Macao, and Japan. At Ningpo his report of Japan and its wealth caused the equipment of nine ships, eight of which foundered, Pinto's ship being driven to the Lew-chew Islands. After a variety of other adventures, Pinto returned a third time to Japan with Francis Xavier in 1548. In 1553, while at Goa on his return to Portugal with his rich fortune, he was induced to devote nearly all his wealth to the foundation of a seminary for propagating the faith in Japan. Returning to Lisbon in 1558, he spent a few years at court, but found the life very stale after his stirring adventures in the East.

The first extant account of his adventures is to be found in a collection of Jesuits' letters published in Italian at Venice in 1565. The full narrative, however, of his life is his own *Peregrinação*, which was first published in quarto at Lisbon in 1614 by Francisco de Herrera. In 1620 appeared a Spanish translation, and in 1628 at Paris a French translation by B. Figuier, followed by two other editions (1645 and 1830). There is also an English translation by H. Cogan (London, 1663 and 1692). See also Barbosa Machado, *Bibl. Lusitana*; Fr. da Sylva, *Dicionario bibliographico Portuguez*; Castello, *Literaria Classica Portuguesa*.

PINTURICCHIO (1454-1513), whose full name was BERNARDINO DI BETTI, the son of a citizen of Perugia, Benedetto or Betto di Biagio, was one of a very important group of painters who inherited the artistic traditions and developed the style of the older Perugian painters such as Bonfigli and Fiorenzo di Lorenzo. According to Vasari he was a pupil of Perugino; and so in one sense no doubt he was, but rather as a paid assistant than as an apprentice. The strong similarity both in design and methods of execution which runs through the works of this later Perugian school, of which Perugino was the oldest member, is very striking; paintings by Perugino, Pinturicchio, Lo Spagna, and Raphael (in his first manner) may often be mistaken one for the other. In most cases, especially in the execution of large frescos, pupils and assistants had a large share in the work, either in enlarging the master's sketch to the full-sized cartoon, in transferring the cartoon to the wall, or in painting backgrounds, drapery, and other accessories. In this way the spirit and individuality of one man could impress itself indelibly on a numerous school of younger artists.

After assisting Perugino in the execution of his frescos in the Sistine Chapel, Pinturicchio was employed by various members of the Della Rovere family and others to decorate a whole series of chapels in the church of S. Maria del Popolo in Rome, where he appears to have worked from 1484, or earlier, to 1492 with little interruption. The earliest of these is an altarpiece of the Adoration of the Shepherds, in the first chapel (from the west) on the south, built by Cardinal Domenico della Rovere; a portrait of the cardinal is introduced as the foremost of the kneeling shepherds. In the lunettes under the vault Pinturicchio painted small scenes from the life of St Jerome. The frescos which he painted in the next chapel, that built by Card. Innocenzo Cibo, were destroyed in 1700, when the chapel was rebuilt by Card. Alderano Cibo. The third chapel on the south is that of Giov. della Rovere, duke of Sora, nephew of Sixtus IV., and brother of Giuliano, who was afterwards Pope Julius II.

This contains a fine altarpiece of the Madonna enthroned between Four Saints, and on the east side a very nobly composed fresco of the Assumption of the Virgin. The vault and its lunettes are richly decorated with small pictures of the life of the Virgin, surrounded by graceful arabesques; and the dado is covered with monochrome paintings of scenes from the lives of saints, medallions with prophets, and very graceful and powerfully drawn female figures in full length, in which the influence of Signorelli may be traced. In the fourth chapel Pinturicchio painted the Four Latin Doctors in the lunettes of the vault. Most of these frescos are considerably injured by damp, but happily have suffered little from restoration; the heads are painted with much minuteness of finish, and the whole of the pictures depend very largely for their effect on the final touchings *a secco*. The last paintings completed by Pinturicchio in this church were the frescos on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. In the centre is an octagonal panel of the Coronation of the Virgin, and round it medallions of the Four Evangelists—the spaces between them being filled up by reclining figures of the Four Sibyls. On each pendentive is a figure of one of the Four Doctors enthroned under a niched canopy. The bands which separate these pictures have elaborate arabesques on a gold ground, and the whole is painted with broad and effective touches, very telling when seen (as is necessarily the case) from a considerable distance below. No finer specimen of the decoration of a simple quadripartite vault can anywhere be seen.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. These rooms, called after their founder the *Appartamenti Borgia*, now form part of the Vatican library, and five of them still retain the fine series of frescos with which they were so skilfully decorated by Pinturicchio. The upper part of the walls and vaults, not only covered with painting, but further enriched with delicate stucco work in relief, are a masterpiece of decorative design applied according to the truest principles of mural ornament,—a much better model for imitation in that respect than the more celebrated Stanze of Raphael immediately over the Borgia rooms. The main subjects are—(1) the Annunciation, the Nativity, the Magi, and the Resurrection; (2) Scenes from the lives of St Catherine, St Antony, and other saints; (3) allegorical figures of Music, Arithmetic, and the like; (4) four figures in half length, with rich arabesques; (5) figures of the planets, the occupations of the various months, and other subjects. The sixth room was repainted by Perino del Vaga.<sup>1</sup>

Though not without interruption, Pinturicchio, assisted by his pupils, worked in these rooms from 1492 till 1498, when they were completed. His other chief frescos in Rome, still existing in a very genuine state, are those in the Cappella Bufalini at the south-west of St Maria in Ara Coeli, probably executed from 1497 to 1500. These are well-designed compositions, noble in conception, and finished with much care and refinement. On the altar wall is a grand painting of St Bernardino of Siena between two other saints, crowned by angels; in the upper part is a figure of Christ in a vesica-glory, surrounded by angel musicians; on the left wall is a large fresco of the miracles done by the corpse of St Bernardino, very rich in colour, and full of very carefully painted heads, some being

<sup>1</sup> See Guattani, *Quadri nell' Appart. Borgia*, Rome, 1820.

portraits of members of the Bufalini family, for whom these frescos were executed. One group of three females, the central figure with a child at her breast, is of especial beauty, recalling the grace of Raphael's second manner. The composition of the main group round the saint's corpse appears to have been suggested by Giotto's painting of St Francis on his bier in S. Croce at Florence. On the vault are four noble figures of the Evangelists, usually attributed to Luca Signorelli, but certainly, like the rest of the frescos in this chapel, by the hand of Pinturicchio. On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists, a work which still exists in a fair state of preservation and unrestored. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed. For these he received fifty gold ducats.

Among his panel pictures the following are the most important. An altarpiece for St Maria de' Fossi at Perugia, painted in 1496–98, now moved to the picture gallery, is a Madonna enthroned among Saints, graceful and sweet in expression, and very minutely painted; the wings of the retable have standing figures of St Augustine and St Jerome; and the *predella* has paintings in miniature of the Annunciation and the Evangelists. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The angels at the sides in beauty of face and expression recall the manner of Lorenzo di Credi or Da Vinci. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several well-executed portraits occur among the kneeling saints. The Virgin, who kneels at Christ's feet to receive her crown, is a figure of great tenderness and beauty, and the lower group is composed with great skill and grace in arrangement. Other important panel paintings by Pinturicchio exist in the cathedral of Spello, in the Siena gallery, at Florence, at Perugia, and in other collections.

In 1501 Pinturicchio painted several fine frescos in S. Maria Maggiore at Spello,—all very decorative, and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinus Pinturichius Pervsinus." They are much injured by damp and clumsy restoration. The most striking of all Pinturicchio's frescos, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1495 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Æneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract, given in full by Milanesi (Vasari, iii. p. 519), is a very interesting one; it specially provides that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. In fact when closely examined the evidence which would give Raphael an important share in the execution of these fine paintings amounts to very little. The document provides for the price of these frescos, namely one thousand gold ducats, to be paid in various instalments. The work was begun early in 1503, but was interrupted for a while by the death of Pius III. His will, however, provided for the completion of the work by his executors, and the whole series were finished in 1507. The subjects are (1) the journey of the young Sylvius Piccolomini to the council of Basel, in the suite of Cardinal Capranica; (2) his reception by James I. of Scotland as envoy from the council of Basel; (3) his being crowned with the poet's laurel by Frederick III.; (4) his reception by Pope Eugenius IV. as ambassador from Frederick III.; (5) outside the wall of Siena he presents to

Frederick III. his bride Leonora, infanta of Portugal; (6) he receives the cardinal's hat from Pope Calixtus III.; (7) he is borne in procession after his election as Pope Pius II.; (8) he presides at a council at Mantua; (9) he canonizes St Catherine of Siena; (10) he arrives in Ancona to promote the crusade against the Turks. In addition to these there is, outside the library, over the door, the Coronation of Pius III.

Though this splendid series of paintings are laid in with true fresco-colours, there is but little *fresco buono* visible; almost the whole is painted over *a secco* with colours much more brilliant in tone than could be used on the wet stucco. This retouching, which was employed by all fresco painters, was used by Pinturicchio more than by most artists. In the lower part of the scene of St Catherine's canonization he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael. The paintings are all finished with much care, but Pinturicchio has not kept to the flat and simply decorative treatment of his earlier manner; there is much more of aerial perspective and distance destroying the apparent solidity of the wall surface.

In 1508 Pinturicchio painted another panel of the Madonna enthroned among Saints for the church of the Minori Conventuali at Spello. It is now over the altar in the sacristy. On his return to Siena he painted a whole series of frescos on the walls of the Palazzo Petrucci, now all destroyed except one scene of the return of Ulysses to Penelope (or possibly Collatinus and Lucretia), which is now in the National Gallery of London, transferred to canvas. One of his last works, painted in 1513, the year of his death, is a very beautiful and highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. Pinturicchio married Grania di Niccolò, and had by her two sons and four daughters; there is probably no truth in the story of his being starved by his wife during his last illness.

The frescos in the Cappella Bufalini were engraved in ten plates by Fran. Giangiacoimo, and published by the Calcografia Camerale of Rome. The Siena library series were engraved by Faucci in the last century, and more recently by Lasinio. Neither set is remarkable for fidelity or spirit. The Siena frescos and those at Spello have been published in chromo-lithograph by the Arundel Society of London.

Pinturicchio's worth as a painter has been for the most part undervalued, partly owing to the very strong prejudice and dislike which tinges Vasari's biography of him. Even recent writers, such as Crowe and Cavalcaselle, have hardly done him justice. A fairer estimate of his position in the history of art is given by Vermiglioli, *Memorie di Pinturicchio*, Perugia, 1837; and in the valuable notes and appendix of Milanesi's edition of Vasari, iii. p. 492–531, Florence, 1878. See also Schmarsow, *Raphael und Pinturicchio in Siena*, Stuttgart, 1880, and *Pinturicchio in Rom*, Stuttgart, 1882, both well illustrated by photolithography. (J. H. M.)

PINZON, a family of wealthy Spanish navigators, of Palos de Moguer, in Andalusia, three members of which—Alonso, Francesco, and Vicente, brothers—were associated with Columbus in his great discovery.

MARTIN ALONZO PINZON, born about the middle of the 15th century, gave material assistance to Columbus in carrying out his project. In the expedition of 1492 Alonso commanded the "Pinta," on board of which his brother Francesco was pilot; another brother, Vicente Yañez, had command of the "Nina." It was at Alonso's persuasion that on October 7th the course of the expedition was changed to the south-west; the island of Guanahani or San Salvador, four days after, was sighted. On November 21, off the coast of Cuba, Alonso separated himself from the expedition, and crowded sail to the westward, hoping to be the first to arrive at the land of gold of which they had heard the natives speak. After an absence of six weeks he rejoined Columbus, who accepted the excuses he gave for his absence. On the return journey Alonso again separated from his leader, probably by design, and when Columbus arrived at Palos on March 15, 1493, he learned that Alonso had already landed at Bayona in Galicia. If his object was to forestall Columbus and obtain the credit of being the discoverer of the New World, his intentions were foiled; he was refused the

audience which he craved of the sovereigns, and very shortly after died, it is supposed of chagrin. Even although it could be proved that Alonzo's intentions were dishonourable, we should remember that it was largely through his liberality that Columbus was enabled to carry out his immortal voyage.

VICENTE YÁÑEZ PINZON, who commanded the "Nina," also gave Columbus material help, and remained loyal to his leader throughout. In after years he made important discoveries on his own account. In 1499 he sailed with four caravels across the Atlantic to the south-west, and on January 20, 1500, he struck the South-American continent at Cape S. Agostinho, its most easterly projection, three months before the Portuguese navigator Cabral reached Brazil, the discovery of which is generally attributed to him. Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, and went as far at least as what is now Costa Rica. After touching at Hayti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in the end of September 1500. Although concessions were made to him, and he was created governor of the newly discovered lands by Ferdinand and Isabella, he does not seem to have ever taken possession. In 1508 we find Vicente sailing with Juan Diaz de Solis along the east coast of South America, in their attempt to find an opening towards the west that would conduct them to the Spice Islands. He did not get beyond the 40th degree of S. lat., about the mouth of the Rio Negro, having passed the mouth of the La Plata without recognizing it. After 1523 all traces of Vicente are lost.

PIOMBO. SEBASTIANO DEL. See SEBASTIANO.

PIOTRKÓW, the chief town of a government of the same name in Russian Poland, and formerly the seat of the high court of Poland, is situated on the railway from Warsaw to Vienna, 90 miles by rail to the south-west of the capital, 5 miles to the west of the river Pilica. Ten years ago it was a poor town of 17,000 inhabitants, but it has grown during the last few years, partly as the seat of the provincial administration, and partly in consequence of the development of trade. In April 1882 it had 23,050 inhabitants, including 3000 military. Its manufactures are still insignificant; it has a few flour-mills, saw-mills, soap-works, and breweries.

PIOZZI, HESTER LYNCH (1741-1821), the daughter of John Salisbury of Bodville, Carnarvonshire, was born there, as it would appear from a protracted dispute between Croker and Macaulay, 27th January 1741. After an education which extended considerably beyond that given to most ladies of her period—for she was acquainted with the learned languages as well as with French, Italian, and Spanish—she was married in 1763 to Henry Thrale, a brewer of Southwark, whose house was at Streatham on the south-east corner of Tooting Beck Common. In this retreat she drew around her many of the most distinguished men of letters of the age. She was introduced to Johnson by Arthur Murphy in the year after her marriage, and for nearly twenty years the sage remained on the closest intimacy with her. He travelled with them in Wales in 1774, and visited France in their company in 1775. Boswell's first visit to Streatham took place in October 1769. Madame D'Arblay was first received there in August 1778. In spite of this intercourse with the principal writers of the day troubles grew upon her in her married life. Her talents were not appreciated by her husband; he was always ill and frequently in pecuniary

anxiety; and when children were born to her they often succumbed to sickness. After some years' illness Mr Thrale died on April 4, 1781, and, as the brewery in the borough sold for £135,000, the widow found herself amply provided for. At the time of Mr Thrale's death Dr Johnson was in declining health, and he soon began to think himself slighted, nor was his indignation abated at the announcement in the spring of 1783 of her engagement to Piozzi, an Italian musician. For a time the engagement was broken off, but it was quickly resumed, and on the 25th of July 1784 they were married. The union provoked the resentment of her children, and the undying denunciations of Dr Johnson; but, when her husband was found to be a man of quiet and inoffensive manners and a careful guardian of his wife's resources, her children acquiesced in the marriage and most of her friends returned to her. Baretti, always her enemy, abused her, and Boswell ridiculed her, but her character has survived the insinuations of the one and the open malevolence of the other, as well as the satiric attacks of Peter Pindar. Piozzi died of gout at Brynbell, March 1809, and from that time his widow's life was chiefly spent in the social circles of Bath and Clifton or in the retirement of Penzance. When long past seventy she took a fancy to William Augustus Conway the actor, and the "love letters" which she wrote to him have been published with a catchpenny title. She died at Clifton, 2d May 1821.

Mrs Piozzi was bright and witty, and possessed of manners which, if not refined, never failed to attract. Several of her literary publications have long since perished from want of vitality, but her little poem of "The Three Warnings" forms a part of most selections of English poetry. Her *Anecdotes of Dr Johnson*, now a scarce book, are contained, "as she herself gave them to the world," in the concluding volume of Napier's *Johnson* (1834), and her notes to Wrasell's *Historical Memoirs* are reprinted in the 1884 edition of that work. The *Anecdotes* and the *Letters to and from Dr Johnson* are inferior in interest only to the work of Boswell. Two editions of the *Autobiography of Mrs Piozzi*, under the editorship of Abraham Hayward, have been issued, and the Rev. Edward Mangin published in 1833, under the disguise of "by a friend," a thin volume of *Piozziana*. Her features are reproduced in the lady's countenance in Hogarth's picture of the Lady's Last Stake.

PIPE (see MUSIC, vol. xvii. p. 77; and ORGAN, *ib.* p. 829). Strutt, in his *Sports and Pastimes of the People of England*, gives representations of the pipe and tabor as used in England in the 14th century to accompany a dancing-dog, a cock on stilts, a horse rearing, &c. From the drawings we cannot ascertain the nature of the pipe represented. We may, however, suppose it to have been similar to the *galoubet* used in France, along with the tabor, from a very remote period. This *galoubet* is a small instrument of the flageolet kind. Its use for more than the last two centuries has been confined to Provence. It has only three finger-holes, and is played with the left hand, whilst the right beats the tabor, which is attached to the performer. The compass of the *galoubet* is two octaves and a tone from D on the third line of the treble clef up to E in *altissimo*. Great skill is required to bring out all the sounds of its compass. Some of the players on this small and imperfect instrument are said to be so dexterous as to be able to perform upon it very difficult pieces of music composed for other instruments, such as the violin, &c. It is always accompanied by the tabor, which is a small drum of a cylindrical form, and rather longer and narrower in its relative proportions than the common drum. In the last century several books of instruction were published at Paris by distinguished performers on the *galoubet*.

PIPE, TOBACCO. The smoking of tobacco in pipes is a custom which prevailed in America for a period of unknown duration previous to the discovery of that con-

inent by Columbus. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in the States of Ohio, Indiana, Illinois, and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type. The pipe, cut out of a single piece of stone, consists of a slightly convex platform or base, generally from 3 to 4 inches in length, and about an inch broad, with the bowl on the centre. A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked. In the commonest forms the bowl is a simple cylinder or urn (fig. 1), but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles, and human heads, often grotesque and fantastic, but always vigorously expressed (fig. 2). These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mississippi valley.

FIG. 1.—"Monitor" Pipe.

FIG. 2.—Heron Pipe.

The wide area over which they, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, &c., are elaborately moulded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connexion with the superstitious rites and usages of the race. The calumet, peace pipe, or medicine pipe is an object of the most profound veneration, entrusted to the care of a highly honoured official, and produced and smoked with much ceremony only on occasions of great importance and solemnity. It is remarkable that, whilst the most ancient American pipes had no separate stem, it is the stem only of the medicine pipe which is the object of veneration among the Indians, the bowl used being a matter of indifference. The favourite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained easily-worked stone of a rich red colour of the Côteau des Prairies, west of the Big Stone Lake in Dakota. The quarries were formerly neutral ground among the warring Indian tribes, many sacred traditions being associated with the locality and its product (see Longfellow's *Hiawatha*, i.). The Babeen Indians of the British-Columbian coast carve from a soft blue clay slate very elaborate and massive pipes with intricate pierced work and fantastic animal forms, the pipe tube being pierced from some protruding part of the sculpture.

There is considerable dispute as to whether pipes for smoking were at all known in Europe previous to the discovery of America. That tobacco-smoking was unknown is certain; but pipes of iron, bronze, and clay have been so frequently found associated with Roman remains and other antiquities as to lead many authorities to maintain that such pipes must have been anciently used for burning incense or for smoking aromatic herbs or hemp. Throughout Great Britain and Ireland small clay pipes are fre-

quently dug up, in some instances associated with Roman relics. These are known amongst the people as elfin, fairy, or Celtic pipes, and in some districts supernatural agencies have been called in to account for their existence. The elfin pipes have commonly flat broad heels in place of the sharp spur now found on clay pipes, and on that flat space the mark or initials of the maker is occasionally found. There is no reason to believe that these pipes are older than the 17th century. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use the implement. The pipe makers of London became an incorporated body in 1619, and from England the other nations of Europe learned the art of making clay pipes. Baillard, in his *Discours du Tabac* (1668) says of the English—"Ces derniers ont inventé les pipes de terre cuite, qui ont cours aujourd'hui par tout le monde."

The habit of smoking with pipes spread with incredible rapidity; and among the various peoples the pipe assumed special characteristics, and its modifications became the medium of conveying social, political, and personal allusions, in many cases with no little artistic skill and humour. The pipe also became the object of much inventive ingenuity, and it varied as greatly in material as in form—wood, horn, bone, ivory, stone, precious and other metals, amber, glass, porcelain, and above all clay being the materials employed in various forms. By degrees pipes of special form and material came to be associated with particular people, so that now we have the elongated painted porcelain bowls and pendulous stem of the German peasantry, the red clay bowl and long cherry wood stem of the Turk, and the very small metallic bowl and cane stem of the Japanese, &c. The most luxurious and elaborate form of pipe is the Persian *kalyān*, hookah, or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base, and the snake or long flexible tube ending in the mouthpiece. The tobacco, which must be previously prepared by steeping in water, is placed in the head and lighted with live charcoal, a wooden stem passes from its bottom down into the water which fills the base, and the tube is fitted to a stem which ends in the bottle above the water. Thus the smoke is cooled and washed before it reaches the smoker by passing through the water in the bottle, and by being drawn through the coil of tube frequently some yards in length. The bottles are in many cases made of carved and otherwise ornamented cocoa-nut shells, whence the apparatus is called *nārgila*, from *nāryil*, a cocoa-nut. Silver, gold, damascened steel, and precious stones are freely used in the making and decoration of these pipes for wealthy smokers.

*Pipe Manufacture.*—The regular pipe-making industries divide into many branches, of which the more important are the clay pipe, meerschaum (real and artificial), and wooden bowl trades. Clay pipes are made in prodigious numbers by hand labour with an iron mould and a steel wire for forming the tube of the stem. Pipe moulding is a very simple operation in pottery, and the work is performed with astonishing celerity. A number of machines have been devised for automatic pipe-moulding; but the manual operations are so rapid and inexpensive that there is little margin for saving by the substitution of machinery. The pipes are very lightly fired so as to keep them soft and porous; and so cheaply made are they that the commoner kinds can be retailed at a profit for a farthing each. The principal centre of the clay pipe industry is at Broseley in Staffordshire, where the trade has been established since the early part of the 17th century. Meerschaum pipes (see MEERSCHAUM, vol. xv. p. 825) are the expensive luxury of the European smoker, and large sums of money are occasionally expended on the artistic treatment of the meerschaum bowl or on the adornment of its adjuncts. The common meerschaum is generally provided with a mouth-piece of amber, but modern ingenuity has succeeded in providing a remarkably clever imitation of both substances, so that a large proportion of the so-called meerschaum pipes are factitious. The headquarters of the meerschaum pipe

industry is at Ruhla in Thuringia, and in connexion with an official inquiry into the German tobacco trade in 1879 the average production of pipes and pipe adjuncts in that district for several years was ascertained. Of pipe bowls there were made yearly 540,000 genuine meerschaums; 5,400,000 artificial meerschaums; 4,800,000 wooden heads; 9,600,000 common porcelain bowls (the favourite of the German peasant); and 2,700,000 fine clay or lava bowls. Further the trade included 15,000,000 pipe stems or tubes of various materials; 19,200,000 adjuncts, such as flexible tubes, chains, tops, &c.; 144,000 pipe cases; 9,600,000 mouth-pieces and cigar-holders of amber, horn, meerschaum, wood, &c.; and finally 15,000,000 complete pipes of various materials. The whole annual value of the industry is estimated at £1,000,000 sterling. The favourite wooden pipe generally known as a briar-wood or briar-root pipe is really made from the roots of the tree heath, *Erica arborea* (French, *bruyère*), principally obtained on the hills of the Maremma and taken thence to Leghorn. There the roots are shaped into blocks each suitable for a pipe, the cutting of the wood so as to avoid waste requiring considerable skill. These blocks are simmered in a vat for twelve hours, which gives them the much appreciated yellowish-brown hue of a good "briar-root." So prepared the blocks are exported for boring and finishing to St Claude (Jura) in France and to Nuremberg, the two rival centres of the wooden pipe trade. (J. P.A.)

**PIPE-FISHES**, small marine fishes, which with the Sea-horses form a distinct family, *Syngnathidae*, of the order of Lophobranchiate Fishes (see *ICHTHYOLOGY*, vol. xii. p. 694). The name is derived from the peculiar form of their

FIG. 1.—*Syngnathus acus*, male, with sub-caudal pouch.

snout, which is produced into a more or less long tube, ending in a narrow and small mouth which opens upwards and is toothless. The body and tail are long and thin, snake-like, encased in hard integuments which are divided into regularly arranged segments. This dermal skeleton shows several longitudinal ridges, so that a vertical section through the body represents an angular figure, not round or oval as in the majority of other fishes. A dorsal fin is always present, and the principal (in some species, the only) organ of locomotion. The ventral fins are as constantly absent, and the other fins may or may not be developed. The gill-openings are extremely small, and placed near the upper posterior angle of the gill-cover. Pipe-fishes are abundant on such coasts of the tropical and temperate zones as offer by their vegetation shelter to these defenceless creatures. They are very bad swimmers, slowly moving through the water by means of the rapid undulatory movement of the dorsal fin. Their tail, even when provided with a caudal fin, is of no use in swimming, and not prehensile as in sea-horses. Specimens, therefore, are not rarely found at a great distance from land, having been resistlessly carried by currents into the open ocean; one species, *Syngnathus pelagicus*, has an extraordinarily wide range over the tropical seas, and is one of the common fishes inhabiting the vegetation of the Sargasso Sea. In pipe-fishes the male is provided with a pouch—in some species on the abdomen, in others on the lower side of the tail—

FIG. 2.—Sub caudal pouch of *Syngnathus acus*, with the young ready to leave the pouch. One side of the membrane of the pouch is pushed aside to admit of a view of its interior. (Natural size.)

in which the ova are lodged during their development. This marsupial pouch is formed by a fold of the skin developed from each side of the trunk or tail, the free margins of the fold being firmly united in the median line throughout the period during which the eggs are being hatched. When the young are hatched the folds separate, leaving a wide slit, by which the young gradually escape when quite able to take care of themselves. Nearly a hundred different species of pipe-fishes are known, of which *Siphonostoma typhle*, *Syngnathus acus* (the Great Pipe-fish, up to 18 inches in length), *Nerophis aquoreus* (Ocean Pipe-fish), *Nerophis ophidion* (Straightnosed Pipe-fish), and *Nerophis lumbriciformis* (Little Pipe-fish) are British species. The last three are destitute of a caudal fin.

**PIPIIT**, French *Pipit*, cognate with the Latin *Pipio* (see *PIGEON*, *supra* p. 84), the name applied by ornithologists to a group of birds having a great resemblance both in habits and appearance to the LARKS (vol. xiv. p. 317), with which they were formerly confounded by systematists as they are at the present day in popular speech, but differing from them in several important characters, and, having been first separated to form the genus *Anthus*, which has since been much broken up, are now generally associated with the WAGTAILS (*q.v.*) in the Family *Motacillidae*.<sup>1</sup> Pipits, of which over fifty species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguei*, the Prairie-Lark of the north-western plains, and *Anthus ludovicianus*, the American Titlark, which last is very nearly allied to the so-called Water-Pipit of Europe, *A. spiolella*. To most English readers the best known species of Pipit is the Titlark or Meadow-Pipit, *A. pratensis*, a bird too common to need description, and abundant on pastures, moors, and uncultivated districts generally; but in some localities the Tree-Pipit, *A. trivialis*, or *A. arboreus* of some authors, takes its place, and where it does so it usually attracts attention by its loud song, which is not unlike that of a Canary-bird, but delivered (as appears to be the habit of all the Pipits) on the wing and during a short circuitous flight. Another species, the Rock-Lark, *A. obscurus*, scarcely ever leaves the sea-coast and is found almost all round the British Islands. The South-African genus *Macronyx*, remarkable for the extreme length of its hind claw, is generally placed among the Pipits, but differs from all the rest in its brighter coloration, which has a curious resemblance to the American genus *Sturnella* (see *ICTERUS*, vol. xii. p. 697), though the bird is certainly not allied thereto. (A. N.)

**PIPIPI**, GIULIO (c. 1492–1546), the head of the Roman school of painting in succession to Raphael. This prolific painter, modeller, architect, and engineer is currently named GIULIO (or JULIO) ROMANO, from the place of his birth—Rome, in the Macello de' Corbi. His name in full was Giulio di Pietro di Filippo de' Giannuzzi,—Giannuzzi being the true family name, and Pippi (which has practically superseded Giannuzzi) being an abbreviation from the name of his grandfather Filippo.

The date of Giulio's birth is a little uncertain. Vasari (who knew him personally) speaks of him as fifty-four years old at the date of his death, 1st November 1546; thus he would have been born in 1492. Other accounts assign 1498 as the date of birth. This would make Giulio young indeed in the early and in such case most precocious stages of his artistic career, and would show him as dying, after an infinity of hard work, at the comparatively early age of forty-eight.

Giulio must at all events have been quite youthful

<sup>1</sup> Pipits can always be distinguished from Larks by having the hind part of the "tarsus" undivided, while the Larks have it scutellated.

when he first became the pupil of Raphael, and at Raphael's death in 1520 he was at the utmost twenty-eight years of age. Raphael had loved him as a son, and had employed him in some leading works, especially in the Loggie of the Vatican; the series there popularly termed "Raphael's Bible" is done in large measure by Giulio,—as for instance the subjects of the Creation of Adam and Eve, Noah's Ark, and Moses in the Bulrushes. In the saloon of the "Incendio del Borgo," also, the figures of Benefactors of the Church (Charlemagne, &c.) are Giulio's handiwork. It would appear that in subjects of this kind Raphael simply furnished the design, and committed the execution of it to some assistant, such as Giulio,—taking heed, however, to bring it up, by final retouching, to his own standard of style and type. Giulio at a later date followed out exactly the same plan; so that in both instances inferiorities of method, in the general blocking-out and even in the details of the work, are not to be precisely charged upon the *caposcuola*. Amid the multitude of Raphael's pupils, Giulio was eminent in pursuing his style, and showed universal aptitude; he did, among other things, a large amount of architectural planning for his chief. Raphael bequeathed to Giulio, and to his fellow-pupil Gianfrancesco Penni ("Il Fattore"), his implements and works of art; and upon them it devolved to bring to completion the vast fresco-work of the "Hall of Constantine" in the Vatican—consisting, along with much minor matter, of the four large subjects, the Battle of Constantine, the Apparition of the Cross, the Baptism of Constantine, and the Donation of Rome to the Pope. The two former compositions were executed by Pippi, the two latter by Penni. The whole of this onerous undertaking was completed within a period of only three years,—which is the more remarkable as, during some part of the interval since Raphael's decease, the Fleming, Adrian VI., had been pope, and his anti-æsthetic pontificate had left art and artists almost in a state of inanition. Clement VII. had now, however, succeeded to the papedom. By this time Giulio was regarded as the first painter in Rome; but his Roman career was fated to have no further sequel.

Towards the end of 1524 his friend the celebrated writer Baldassar Castiglione seconded with success the urgent request of the duke of Mantua, Federigo Gonzaga, that Giulio should migrate to that city, and enter the duke's service for the purpose of carrying out his projects in architecture and pictorial decoration. These projects were already considerable, and under Giulio's management they became far more extensive still. The duke treated his painter munificently as to house, table, horses, and whatever was in request; and soon a very cordial attachment sprang up between them. In Pippi's multifarious work in Mantua three principal undertakings should be noted. (1) In the Castello he painted the History of Troy, along with other subjects. (2) In the suburban ducal residence named the Palazzo del T (this designation being apparently derived from the form of the roads which led towards the edifice) he rapidly carried out a rebuilding on a vastly enlarged scale,—the materials being brick and terra-cotta, as there is no local stone,—and decorated the rooms with his most celebrated works in oil and fresco painting—the story of Psyche, Icarus, the Fall of the Titans, and the portraits of the ducal horses and hounds. The foreground figures of Titans are from 12 to 14 feet high; the room, even in its structural details, is made to subserve the general artistic purpose, and many of its architectural features are distorted accordingly. Greatly admired though these pre-eminent works have always been, and at most times even more than can now be fully ratified, they have suffered severely at the hands of restorers, and modern eyes see

them only through a dull and deadening fog of renovation. The whole of the work on the Palazzo del T, which is of the Doric order of architecture, occupied about five years. (3) Pippi recast and almost rebuilt the cathedral of Mantua; erected his own mansion, replete with numerous antiques and other articles of vertu; reconstructed the street architecture to a very large extent, and made the city, sapped as it is by the shallows of the Mincio, comparatively healthy; and at Marmiruolo, some five miles distant from Mantua, he worked out other important buildings and paintings. He was in fact, for nearly a quarter of a century, a sort of Demiurgus of the arts of design in the Mantuan territory.

Giulio's activity was interrupted but not terminated by the death of Duke Federigo. The duke's brother, a cardinal who became regent, retained him in full employment. For a while he went to Bologna, and constructed the façade of the church of S. Petronio in that city. He was afterwards invited to succeed Antonio Sangallo as architect of St Peter's in Rome,—a splendid appointment, which, notwithstanding the strenuous opposition of his wife and of the cardinal regent, he had almost resolved to accept, when a fever overtook him, and, acting upon a constitution somewhat enfeebled by worry and labour, carried him off on 1st November 1546. He lies buried in the church of S. Barnaba in Mantua. At the time of his death Giulio enjoyed an annual income of more than 1000 ducats, accruing from the liberalities of his patrons. He left a widow, and a son and daughter. The son, named Raffaello, studied painting, but died before he could produce any work of importance; the daughter, Virginia, married Ercole Malatesta.

Wide and solid knowledge of design, combined with a promptitude of composition that was never at fault, formed the chief motive power and merit of Giulio Romano's art. Whatever was wanted, he produced it at once, throwing off, as Vasari says, a large design in an hour; and he may in that sense, though not equally so when an imaginative or ideal test is applied, be called a great inventor. It would be difficult to name any other artist who, . . . and as the plastic and pictorial embellisher . . . : Jueed a total of work so fully and homogeneously his own; hence he has been named "the prince of decorators." He had great knowledge of the human frame, and represented it with force and truth, though sometimes with an excess of movement; he was also learned in other matters, especially in medals, and in the plans of ancient buildings. In design he was more strong and emphatic than graceful, and worked a great deal from his accumulated stores of knowledge, without consulting nature direct. As a general rule, his designs are finer and freer than his paintings, whether in fresco or in oil—his easel pictures being comparatively few, and some of them the reverse of decent; his colouring is marked by an excess of blackish and heavy tints.

Giulio Romano introduced the style of Raphael into Mantua, and established there a considerable school of art, which surpassed in development that of his predecessor Mantegna, and almost rivalled that of Rome. Very many engravings—more than three hundred are mentioned—were made contemporaneously from his works; and this not only in Italy, but in France and Flanders as well. His plan of entrusting principally to assistants the pictorial execution of his cartoons has already been referred to; Primaticcio was one of the leading coadjutors. Rinaldo Mantovano, a man of great ability who died young, was the chief executant of the Fall of the Giants; he also co-operated with Benedetto Pagni da Pesce in painting the remarkable series of horses and hounds, and the story of Psyche. Another pupil was Fermo Giusoni, who remained settled in Mantua. The oil pictures of Giulio Romano are not generally of high importance; two leading ones are the Martyrdom of Stephen, in the church of that saint in Genoa, and a Holy Family in the Dresden Gallery. Among his architectural works not already mentioned is the Villa Madama in Rome, with a fresco of Polyphemus, and boys and satyrs; the Ionic façade of this building may have been sketched out by Raphael.

Vasari gives a pleasing impression of the character of Giulio. He was very loving to his friends, genial, affable, well-bred, temperate in the pleasures of the table, but liking fine apparel and a handsome scale of living. He was good looking, of middle height, with black curly hair and dark eyes, and an ample beard; his portrait, painted by himself, is in the Louvre. (W. M. R.)

PIPPIN, or PEPRIN, a name borne by several members of the Carolingian family. (1) Pippin of Landen, or Pippin the Old, mayor of the palace, died 639. (2) His grandson, Pippin of Heristal, the father of Charles Martel, died 714. (3) Martel's son, Pippin the Short, king of the Franks, died 768. See, for these three, FRANCE, vol. ix. p. 530 sq. (4) Pippin, son of Charles the Great (776-810), was his father's deputy in Italy, and as such was anointed "king for Italy" by Pope Adrian I. in 781. (5) Pippin, second son of Louis the Pious, appointed king of Aquitaine by his father in 817, died in 838 after a reign spent in the family conflicts of the period. (6) The son of the last-named Pippin was called to the throne by the Aquitanians on his father's death, and maintained himself with varying fortunes against Charles the Bald, to whom Louis had given the vacant throne, till in 864 he was taken by treachery and soon died in confinement.

PIQUA, a city of Miami county, Ohio, U.S., is situated in a rich agricultural district on the Miami river, on the Miami and Erie Canal, and on the Pittsburgh, Cincinnati, and St. Louis and the Cincinnati and Michigan railways, about 90 miles N. by E. of Cincinnati. Besides a large agricultural trade the city has woollen manufactures, iron foundries, and agricultural machine works. The population, 3277 in 1850, was 5967 in 1870 and 6131 in 1880.

PIQUET, a game at cards. The name, of uncertain etymology, is probably from *pique* (the spade suit). The Germans had formerly a *Schwerter* game, the packs used being like piquet packs. The *pique* of French cards corresponds to the *spade* (sword) of Italian and to the *espadas* of Spanish cards. Hence *piquet* may be the *sword game*.

It seems likely that piquet is a development of *ronfa*, a game mentioned by Berni in 1526; *la ronfle* (included in Rabelais's list, circa 1530) may be regarded as the same game. The point at piquet was anciently called *ronfle*.

The Spanish name of the game was *cientos* (*centum*, a hundred). Piquet was played in England under the name of *cent*, or *sant*, probably as early as 1550 (contemporaneously with the marriage of Mary to Philip of Spain). About the middle of the 17th century (shortly after the marriage of Charles I. to Maria Henrietta of France) the name *cent* was dropped in England, and the French equivalent, *piquet*, adopted.

Piquet is played by two persons, with a pack of thirty-two cards,—the sixes, fives, fours, threes, and twos being thrown out from a complete pack. Until recently the *partie* was the best of five games of a hundred up (a player not obtaining fifty losing a double game). But now the *partie* is generally determined in six hands, the player making the largest aggregate score being the winner. The number of points won is the difference between the two scores, with a hundred added for the game. If, however, the loser fails to make a hundred in six hands, the number of points won is the two scores added together, with a hundred for the game. Piquet played in this way is called *Rubicon Piquet*.

The dealer (see "Laws") deals twelve cards to his adversary and twelve to himself, by two at a time or by three at a time to each alternately. He then places the undealt cards, called the *stock*, face downwards on the table.

The players now look at their hands and *discard*, i.e., put out, such cards as they deem advisable, and take in an equivalent number from the stock. The elder hand (non-dealer) may exchange five or any less number. He separates his discard from his hand, places it face downwards on the table, and takes from the top of the stock the number discarded. If he discards less than five, he must state how many he leaves. He is entitled to look at cards he leaves, replacing them face downwards on the top of the stock.

The younger hand may exchange three cards or any less number. If the elder hand leaves any cards, the younger may exchange as many as remain in the stock, discarding an equal number. He takes his cards from the top of the stock, including any left by the elder hand. If the younger hand leaves any cards, he announces

the number left. He has the option of looking at cards he leaves. If he looks at them, he must show them to the elder hand, after the elder has named the suit he will first lead, or has led a card. If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before he plays to the card first led, or, if so required, after the dealer has named the suit he will first lead.

Each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next *calls* his point, sequences, and quatorzes or tries, and, if good, scores for them.

The *point* must be called first or the right to call a point is lost. It is scored by the player who announces the suit of greatest strength, valued thus: ace, 11; court cards, 10 each; other cards, the number of pips on each. Thus, if the elder hand's best suit is ace, king, knave, nine, eight, he calls "five cards." If the younger hand has no suit of five cards, he says "good." The elder hand then says "in spades," or whatever the suit may be, or shows his point face upwards. If the younger hand has a suit of more than five cards, he says "not good." If the younger hand has also five cards, he says "equal" or "what do they make?" when the elder calls "forty eight" (or "making eight," short for forty-eight). The younger must not inquire what the point makes unless he has an equal number of cards. If the younger hand's five cards make less than forty-eight he says "good"; if exactly forty-eight, he says "equal"; if more than forty-eight, he says "not good."

The player whose point is good reckons one for each card of it; if the points are equal neither player scores for point.

*Sequences* are usually called next, the elder hand stating what his best sequence is, and the younger saying, "good," "equal," or "not good," as in the case of the point. Any three or more consecutive cards of the same suit held in hand constitute a sequence. The order of the cards is as follows:—ace (highest), king, queen, knave, ten, nine, eight, seven (lowest). A sequence of three cards is called a *tierce*; of four, a *quart*; of five, a *quint*; of six, a *sixième*; of seven, a *septième*; of eight, a *huitième*. A tierce of ace, king, queen is called a *tierce major*; a tierce of king, queen, knave is called *tierce to a king* (and so on for other intermediate sequences according to the card which heads them); a tierce of nine, eight, seven is called a *tierce minor*. Sequences of four or more cards follow the same nomenclature, e.g., ace, king, queen, knave is a quart major; knave, ten, nine, eight is a quart to a knave; and so on.

A sequence of a greater number of cards is good against a sequence of a smaller number; thus, a quart minor is good against a tierce major. As between sequences containing the same number of cards, the one headed by the highest card is good; thus, a quart to a queen is good against a quart to a knave. Only identical sequences can be equal.

The elder hand announces, say, a quint major. If the younger has a *sixième* he says "not good"; if he has a quint major he says "equal"; if he has a lower sequence, or no sequence, he says "good." The player whose sequence is good reckons one for each card of it, and ten in addition for quints or higher sequences. Thus a tierce counts three; a quart, four; a quint, fifteen (5+10); a *sixième*, sixteen; and so on. If the elder hand's sequence is good, he names the suit, or shows it face upwards.

If the highest sequence (or the sequence first called) is good, all lower sequences can be reckoned, notwithstanding that the adversary has a sequence of intermediate value. For example, A has a quart to a queen (good), and a tierce minor. He calls and reckons seven, notwithstanding that B has a quart to a knave. B's quart counts nothing.

If the highest sequence is equal, neither player scores anything for sequence, even though one player may hold a second sequence of equal or inferior value.

*Quatorzes* are composed of four aces, four kings, four queens, four knaves, or four tens; *trios* of three of any of these. They are called and reckoned as before, except that here there can be no equality. A quatorze, if good, reckons fourteen; a trio, if good, reckons three. Any quatorze is good against a trio; if each player has a quatorze the highest is good; the same if each has a trio. As in the case of sequences, anything that is good enables the player to reckon all smaller quatorzes or trios in his hand. A quatorze or trio is called thus:—the elder hand says "four aces," "three queens," or as the case may be; the younger replies "good" or "not good," as before. When a player calls a trio of a denomination of which he might hold a quatorze, the adversary is entitled to be informed which card is not reckoned. Thus, A, "good"; A says "I do not reckon the king of diamonds," or whichever king it may be that he has put out or suppresses.

When the elder hand has done calling he leads a card. Before playing to this card, the younger hand reckons all that he has good, stating of what cards his claims are composed, or showing the cards claimed for.

The next step is *playing* the hands. The elder hand leads any

card he pleases; the younger plays to it. The younger hand must follow suit if able; otherwise he may play any card he thinks fit. The two cards thus played constitute a trick. The trick is won by the higher card of the suit led. It is not compulsory to win the trick if able to follow suit without. The winner of the trick leads to the next, and so on until the twelve cards in hand are played out.

During the play of the hands the leader counts one for each card led, whether it wins the trick or not. If the leader wins the trick, his adversary reckons nothing that trick; but if the second player wins the trick he also counts one; and so on. The winner of the last trick counts two instead of one.

The tricks are left face upwards on the table, in front of the player who wins them. They may be examined by either player at any time.

If each player wins six tricks the cards are divided, and there is no further score. If one player wins more than six tricks he wins the cards, and adds ten to his score. If one player wins every trick, he wins a *capot*, and scores forty for the cards, instead of ten.

During the play of the hand, a player is entitled to be informed as to any cards his adversary holds which he has reckoned as good, or has declared to be equal. A player may require his adversary to exhibit any such cards; but the usual practice is to reply to all necessary questions with regard to them, such as "how many of your point?" meaning how many in hand, "how many of your three!" and so on.

During the progress of the hand each player repeats aloud the amount of his score for the time being (see example). At the end of the hand the number scored is recorded on a ruled card. Each player has a card and writes down the scores of both himself and his opponent. At the end of the sixth hand, the totals are recorded, and the necessary subtraction or addition made. The scores are then compared. If there is any difference in the written scores, a player's score of his own hand is deemed to be the correct one.

**Example.**—A (elder hand) has dealt him ace, king, knave of spades; ace, queen, knave, eight of hearts; knave, eight, seven of clubs; and nine, eight of diamonds. He discards king of spades; eight, seven of clubs; and nine, eight of diamonds. He takes in nine, eight of spades; king of hearts; nine of clubs; and king of diamonds.

B (younger hand) has ten, seven of spades; ten, nine, seven of hearts; king, queen, ten of clubs; and ace, queen, knave, ten of diamonds. He discards seven of spades; and nine, seven of hearts. He takes in queen of spades; ace of clubs; and seven of diamonds.

The hand then proceeds thus. A (calls his point) "five cards." B (says) "equal," or "what do they make?"

A "forty-nine," or "making nine." B "good." A (counting his point) "five" and (counting his sequence, which is good) "a quart major, nine. Three knaves!" B "not good."

A (leads ace of hearts and says) "ten." B "four tens, fourteen, and three queens, seventeen" (plays the ten of hearts).

A (leads the remaining hearts and says) "eleven, twelve, thirteen, fourteen." B (plays seven, ten, knave, queen of diamonds, and repeating his score, says) "seventeen."

A has now five tricks, and in order to win the cards should lead any card but a high spade. He leads king of diamonds, and says "fifteen." B (wins with ace and says) "eighteen," (and then leads the winning clubs, saying) "nineteen, twenty, twenty-one, twenty-two."

A (leads ace, knave of clubs, and repeating his score says) "fifteen." B (leads queen of spades and says) "twenty-three."

A (wins with ace and says) "sixteen" (and leads knave, saying) "eighteen" (and adding ten for the cards) "twenty-eight."

A then writes on his scoring card 23; 23. B writes on his 23; 23. The pack is collected, and the next hand commences.

Three scores (omitted in order to simplify the description of the game) have yet to be mentioned.

**Carte Blanche.**—If either player has neither king, queen, nor knave in the hand dealt him, he holds *carte blanche*, for which he scores ten. As soon as a player discovers he has a *carte blanche*, he must tell his adversary; this he usually does by saying "discard for *carte blanche*." The adverse discard is then made (as explained under discarding), after which the *carte blanche* is shown by dealing the cards quickly one on top of the other, face upwards on the table.

**Pique.**—If the elder hand scores, in hand and play, thirty or more, before the younger counts anything, he gains a *pique*, for which he adds thirty to his score. For example, A has a quint major, good for point and sequence, and three aces, also good. For these he counts twenty-three in hand. He next leads the quint major (twenty-eight), one of the aces and another card, making him thirty. He then adds thirty for the pique and calls his score "sixty."

**Repique.**—If a player scores, in hand alone, thirty or more, before his adversary reckons anything, he gains a *repique*, for which he adds sixty to his score. Thus, point, quint, and quatorze, all good, make thirty-four. A player holding these adds sixty for the repique, and calls his score "ninety-four."

The order in which the scores accrue is of importance. For the sake of convenience, the elder hand finishes his reckoning before the younger begins. The scores, however, whether made by the elder or younger hand are recordable in the following order:—(1) *carte blanche*; (2) point; (3) sequences; (4) quatorzes and trios; (5) points made in play; (6) the cards. This will often affect a pique or repique. Thus, a pique can only be made by the elder hand, as the one he reckons in play when he leads his first card counts before points subsequently made in play by the younger hand. The younger, therefore, cannot make thirty in hand and play before the elder scores one. But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued, because scores made in hand have precedence of points made in play. The elder leads his first card and counts for it before the younger reckons, simply as a convenient way of stating that he has nothing in hand which is good. Again, say A has a quint (good), a tierce, and a quatorze (good). He scores thirty-two in hand alone; but, if his point is not good, he does not gain a repique, because the younger hand's point is recordable in order before the sequences and quatorze. And again, say A has a *huitième* (good for twenty-six), and a tierce, and leads a card thus reaching thirty in hand and play. B has three tens. The trio reckoning in order before the point made in play by A saves a pique.

**Carte blanche**, taking precedence of all other scores, saves piques and repiques. It also counts towards piques and repiques. Thus, a player showing *carte blanche*, and having point and quint, both good, would repique his adversary.

A *capot* does not count towards a pique, as the *capot* is not made in play. It is added after the play of the hand is over.

A player who reckons nothing that hand as a penalty (see "Laws") is not piqued or repiqued if he holds any cards which, but for the penalty, would have reckoned before his adversary reached thirty.

Equalities do not prevent piques or repiques. A player who has an equal point or sequence scores nothing for it. Therefore if, notwithstanding the equality, a player makes thirty, in hand and play, or in hand, by scores which reckon in order before anything his adversary can count, he gains a pique or a repique.

**Hints to Players.**—On taking up your hand look for *carte blanche*.

Before discarding, ascertain what there is against you. Thus: if you have knave or ten of a suit, there is no quint against you in that suit.

When discarding, elder hand, your main object is to plan an attack. Younger hand, on the contrary, should guard his weak places and then see if he has a chance of attacking anywhere. Thus, the elder hand may freely unguard kings and queens, or discard whole suits of which he has indifferent cards only. The younger should do just the reverse, keeping guards to kings and queens, and should not leave himself blank of a weak suit, as his small cards may guard high ones taken in.

In most hands, and especially younger hand, it is essential to keep the whole of your best suit for point. Gaining the point makes an average difference of at least ten to the score; and, what is of more consequence, it saves piques and repiques.

The cards are next in importance to the point. In discarding you should, when in doubt, take the best chance of dividing or winning the cards. Winning the cards instead of losing them makes a difference of about twenty-three points. Hence, especially elder hand, you should not necessarily keep the longest suit for point, if that suit is composed of low cards, and keeping it involves the discard of high cards from other suits.

As a rule, it is not advisable to leave any cards. The younger hand is at less disadvantage in leaving a card than the elder; for a card left by the elder can be taken by the younger; but a card left by the younger is only excluded from his hand. A card may generally be left when there is a chance of a great score if the cards in hand are not parted with, there being at the same time no pique or repique against you.

It is generally right to keep unbroken suits. Having made up your mind to discard from a given suit, you should throw the whole of it, except (a) winning cards; (b) guards to kings or queens, especially younger hand; or (c) cards which make up a quatorze or trio. It is better to keep cards in sequence than cards not in sequence. Trios should be kept if they can be retained without injury to the hand in other respects; but it is seldom advisable to put out a high card for the sake of keeping a trio of knaves or tens, especially if there is a quatorze against you.

The discard is further affected in the last hand of a *partie* by the state of the score. Thus, if you are a long way behind, and your only chance is a desperate discard, in order to keep cards which may possibly give you a pique or a repique, you may run considerable risk with that object. On the other hand, if you are well ahead, make a safe discard, i.e., one which is likely to win the cards or to keep your adversary back.

When taking in after discarding, count that you leave the full number of cards for the younger hand, the penalty for taking in one of your adversary's cards being that you can reckon nothing

that deal. The younger hand should also count that the proper number of cards are in the stock, before he takes in, as, if he mixes one of the elder's cards with his hand, he can reckon nothing that deal.

After taking in and before calling your hand, look through it and your discard to ascertain what remains against you. If there is anything against you which is not called, you will probably be able to judge from this some portion of the discard, and will so be assisted in playing the cards. But implicit reliance must not be placed on this. For experienced players not unfrequently omit to call some small score, such as a tierce, in order intentionally to mislead you. This manœuvre (called *sinking a score*) is especially resorted to when a player has a high card unguarded. In order to induce you to believe that it is guarded, he will put up with the loss of several points in calling, on the chance of recouping himself by afterwards saving or winning the cards in consequence of your misconceiving his discard.

If your adversary calls a point which is not good, you should at once note in which suit it is (or may be), in order to count the hand. If the younger hand admits a point to be good (as regards the number of cards that compose it), the elder should observe whether the younger could possibly have had equal or better in any suit. If so he has probably put out that suit. But it may be that the younger hand, if a good judge of the game, will admit the number of cards of a point to be good when he has an equal number. Thus:—A calls five cards, and B knows, from examining his hand and discard, that there is only one suit in which A can have five cards, and that they make fifty. B has five cards making forty-nine. B should promptly reply "good," although he has five cards himself; because he ought to know that A's five cards are better than his. By saying "equal," he unnecessarily exposes his hand.

In playing the cards, you must be guided a good deal by what your adversary has called, and, to some extent, by what he has not called. You will generally know several cards in the adverse hand, or will be able to mark some that have been put out. Sometimes you will know all the cards. Thus, if the younger hand fails to follow suit to your first lead in which you could only have five cards, it is evident he has put out three cards of that suit, and you know every card in his hand.

Failing direct indications, lead the point, unless you have a small point and there is a tenace in that suit against you.

When playing to the opponent's lead, keep guards to kings and queens. Having the choice between throwing a card you have declared and one you have not, prefer the former.

If you can make a pique, lead your winning cards one after the other, without considering how many of the remaining tricks you will lose. There is one exception to this:—in the sixth hand, if your losing the cards will enable the younger hand to save his rubicon, and your score is such that you can win the *partie* without the pique, you should forego the pique, when by not leading out your winning cards immediately you can divide or win the cards.

When you have five or six tricks and a winning card, lead the winning card, unless certain that your opponent has cards of that suit. By playing otherwise, you risk eleven points for the chance of gaining one for the last trick. This, of course, is liable to a similar exception as the previous case, viz., in the sixth hand with five tricks up, if you must win the cards or the last trick to win the *partie* or to save the rubicon.

In the sixth hand, if a player has scored less than a hundred, he should consider, before calling or playing, whether he can make his aggregate score up to a hundred or more. If he cannot, his object should be to reckon as little as he can, and to prevent his adversary from scoring, by making his point or sequence equal (if possible), and by endeavouring to divide the cards. If he is satisfied he cannot divide the cards, and there is no capot against him, he is at liberty to score two (one for a trick he wins, and one for a card he plays), and to throw his cards down, allowing the adversary to reckon thirteen in play.

On the other hand, a player who is ahead, and who sees his adversary cannot reach a hundred, should endeavour to prevent the declaration of equalities, and, if he cannot win the cards himself, should play to lose them.

During the calling and play of the hand, always keep in mind your adversary's score and satisfy yourself that he does not reckon too many. Mistakes occur, even among the most honourable players. If your adversary reckons too few, you are not bound to correct him.

*Laws of Piquet.*—1. A player may shuffle either pack, above the table. The dealer has the right to shuffle last. 2. A cut must consist of at least two cards. 3. Highest has choice of deal and cards. (Ace highest, seven lowest.) 4. If a card is exposed in cutting or before dealing, there must be a fresh cut. 5. The mode of distributing the cards (by twos or by threes) must not be altered during the *partie*. 6. The stock must be placed, in one packet, two downwards, between the players. 7. If the cards are dealt wrongly, error may be rectified before either player has taken up his hand, or the adversary may demand a fresh deal. 8. If a card belonging to the elder hand or the stock is exposed when dealing, the adversary has the option of a fresh deal. If there is a faced card in the pack, there must be a fresh deal.

9. If, after the deal is completed, more than one card is found to have been dealt wrongly, or nine cards are found in the stock, there must be a fresh deal. The same if the wrong pack is dealt with, and the error is discovered before either player has taken up his cards; otherwise the packs remain changed. 10. If only one card has been dealt wrongly, the elder hand, after looking at his cards and before taking in a card, has the option of a fresh deal, and if there are only seven cards in the stock, he may alter his discard (see Laws 12 sq.). 11. The players deal alternately. If a player deals out of turn, and the error is discovered by either player before he takes up his cards, the deal is void, and the right dealer deals. If the error is discovered later, the elder hand must deal twice running with his own pack, unless that or the next deal is the last of the *partie*. 12. Each player is bound to discard at least one card (but see Laws 21, 22, and 23). 13. When taking in, the cards must be taken in order from the top of the stock. 14. After taking a card, a player cannot alter his discard; and if he then takes back any of his discard, he must play with more than twelve cards (see Law 30); if after taking a card he mixes any of his hand with his discard, he must play with less than twelve cards (see Law 20). 15. If either player, when taking in, exposes a card of the stock belonging to his adversary, he can reckon nothing that deal. 16. If either player mixes with his hand a card of the stock which belongs to his adversary, he can reckon nothing that deal; or the adversary may have a fresh deal. If he stands the deal he can only take in such of his cards as have not been mixed. 17. If a player discards more cards than he takes in, he must play with less than twelve cards (see Law 20). 18. If a player discards fewer cards than he takes in, he can reckon nothing that deal. 19. The adversary has the option of not enforcing the penalty of reckoning nothing that deal. 20. If the younger hand leaves any cards and mixes them with his discard, without showing them to the elder hand, the elder, after leading a card, is entitled to see the younger's discard. 21. If the elder hand elects to stand the deal when one card has been dealt wrongly, and he has thirteen cards, he must discard one card more than he takes in, and must discard at least two cards. If there are eight cards in the stock, the younger hand discards one less than he takes in, and if he only takes one card he need not discard any; if there are seven cards in the stock, and the elder hand discards six cards and takes five, the younger hand can only take two cards. 22. If the elder hand elects to stand the deal when he has eleven cards, and there are eight in the stock, he must discard one less than he takes in; if he only takes one card he need not discard any. The younger hand must discard one more than he takes in, and must discard at least two cards. 23. If the elder hand elects to stand the deal when he has twelve cards, and there are seven in the stock, he discards the same number as he takes in; the younger discards one more than he takes in, and must discard at least two cards. 24. When the elder hand's call is good against the cards, it is sufficient if he states the number of cards that compose it; if not he must say what it makes or to what card it is, or the value of the cards of which it consists. 25. The elder hand calling too little may correct his miscall before it has been replied to by the younger hand; and the younger hand, allowing a correct call to be good or equal, when he holds better, may correct his reply before the elder hand has made another call, or, if there is no further call, before the elder hand has led a card. 26. If a player calls what he does not hold, he may correct his call before the younger hand has played to the first trick; and, if the younger hand has miscalled, the elder hand may take up his card and play differently. In the absence of correction, the offender can reckon nothing that deal, and the adversary, on discovery of the error, can reckon anything he has good, which is not barred by a correct call made in addition to the miscall. But there is no penalty for calling anything which a player could not possibly hold in his hand and discard taken together, nor for misnaming a suit, nor for misnaming the rank of a sequence, when one of the counting value named is held, provided the claim could not have been held in the hand and discard taken together; and, if a player voluntarily shows what he claims for, he is liable to no penalty for miscalling it. 27. A player who calls anything which is allowed to be good or equal must show the cards called at any time they are asked for during the play of the hand. 28. When the younger hand has played to the first trick, neither player can reckon anything omitted (but see Law 26). 29. A player is liable to no penalty for playing with less than twelve cards. His adversary counts as tricks all cards that cannot be played to. 30. If a player plays with more than twelve cards, he can reckon nothing that deal; but his cards, though not good to score, are good to bar his adversary. 31. A card led or played cannot be taken up (but see Law 26), but cards accidentally dropped may be retaken. Also, if the leader leads several cards consecutively without waiting for them to be played to, and the adversary plays too many cards, he may retake the extra ones; and cards subsequently played in error must be taken up and played over again. Or, if a player leads out of turn, he may take up his card unless it has been played to. Or, if a player does not follow suit when able, the card played in error and all cards subsequently played must be taken up and played over again. Or, if a player misinforms his adversary when asked what cards he holds that have been allowed to be good or equal, the adversary may retake all the cards he has subsequently played, and may play differently. 32. Errors in counting the hand, if proved, may be rectified before the player in error has seen his next hand. 33. If both players score the same number in six deals, each deals once more, when the *partie* is concluded, even if there should be a second tie. 34. If the loser fails to score a hundred, he is rubiconed, whether the winner's score reaches a hundred or not. 35. The deal in which the discovery of an incorrect pack is made is void. All preceding deals stand good. 36. A bystander calling attention to any error or oversight, and thereby affecting the score, may be called upon to pay all stakes and bets of the player whose interest he has prejudicially affected.

See Edmond Hoyle, *A Short Treatise on the Game of Piquet* (1744); "Cavendish," *The Laws of Piquet and of Rubicon Piquet, adopted by the Portland Club, with a Treatise on the Game* (1852). (H. J.)

**PIRACY.** Sir Edward Coke (*Instit.* iii. 113) describes a pirate (Latin *pirata*, from Greek *πειρατής*) as *hostis humani generis*, and as a rover and robber upon the sea. Piracy may be defined in law as an offence which consists in the commission of those acts of pillage and violence upon the high seas which on land would amount to felony. By the ancient common law of England piracy, if committed by a subject, was deemed to be a species of treason, being contrary to his natural allegiance, and by an alien to be felony; but since the Statute of Treasons, 25 Edw. III. c. 2 (1351–52), piracy has been held to be felony only. Formerly this offence was only cognizable by the Admiralty courts, whose proceedings were based upon the

civil law, but by the statute 28 Hen. VIII. c. 15 (1536) a new jurisdiction proceeding according to the common law was set up which, modified and regulated by subsequent enactments, such as 39 Geo. III. c. 37 (1798-99), 4 & 5 Will. IV. c. 36 (1834), and 7 & 8 Vict. c. 2 (1844), continues to be the tribunal by which offenders of this description are tried.

Piracy, being a crime not against any particular state but against all mankind, may be punished in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the law of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), it is not allowed to kill them without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

The earliest of all sea-rovers were perhaps the Phœnicians. During the heroic age of Greece piracy was universally practised. In the Homeric poems frequent mention is made of piracy, which indeed was held in honourable estimation,—the vocation of a pirate being recognized, so that a host, when he asked his guest what was the purpose of his voyage, would enumerate enrichment by indiscriminate maritime plunder as among those projects which might naturally enter into his contemplation. So late as the time of Solon the Phœceans, on account of the sterility of their soil, were forced to roam the seas as pirates. That legislator tolerated whilst he regulated the association of sea-rovers which he found established by inveterate usage. The prevalence of the piratical spirit in Greece in the early ages may perhaps be explained by the number of small independent states into which the country was divided, and the violent animosity subsisting among them. In this way predatory habits were diffused and kept alive. As a more regular system of government grew up, and a few states such as Athens and Corinth had become naval powers, piracy was made a capital offence. It was, however, never entirely put down. Cilicia was at all times the great stronghold of the pirates of antiquity, and in consequence of the decline of the maritime forces which had kept them in check they increased so much in numbers and audacity as to insult the majesty of Rome itself, so that it became necessary to send Pompey against them with a large fleet and army and more extensive powers than had ever previously been conferred on any Roman general. The Etruscans were notorious sea-rovers who infested the Mediterranean; and Polybius relates that the Romans imposed upon the Carthaginians as a condition of peace the stipulation that they should not sail beyond Cape Faro, either for the purposes of trade or piracy.

Hallam (*Middle Ages*, iii. 336) says that in the 13th and 14th centuries a rich vessel was never secure from attack, and neither restitution nor punishment of the criminals was to be obtained from Governments. Hugh Despenser seized a Genoese vessel valued at 14,300 marks, for which no restitution was ever made. The famous Hanseatic League was formed in the middle of the 13th century in northern Germany chiefly for the purpose of protecting the ships of the confederated cities from the attacks of the pirates by which the Baltic was then infested.

A graphic account of piracy as it existed at the end of the 16th century in European waters, especially on the English, French, and Dutch coasts, will be found in Motley, *Hist. United Netherlands* (vols. iii. and iv.). The nuisance was not abated in Europe until the feudal system had been subverted and the ascendancy of the law finally secured. In more modern times some of the smaller West India Islands became a great resort of pirates, from which,

however, they have for many years been driven; for continued acts of piracy the city of Algiers was successfully bombarded by the British fleet under Lord Exmouth as lately as August 1816; and pirates are still not unfrequently met with in the Indian and Chinese seas, but piracy in its original form is no longer in vogue. The BUCCANEERS (*q.v.*) were cruel piratical adventurers of a later date who commenced their depredations on the Spaniards soon after they had taken possession of the American continent and the West Indies, although there was a time when the spirit of buccaneering approached in some degree to the spirit of chivalry in point of adventure. Scaliger observes in a strain of doubtful compliment, "Nulli melius piraticam exercent quam Angli." The first levy of ship money in England in 1635 was to defray the expense of chastising these pirates. The buccaneering confederacy was broken up through the peace of Ryswick in 1697.

At a very early period of English history the law provided for the restitution of property taken by pirates, if found within the realm, whether belonging to strangers or Englishmen; but any foreigner suing for the recovery of his goods was required to prove that at the time of the capture his own sovereign and the sovereign of the captor were in mutual amity, for it was held that piracy could not be committed by the subjects of states at war with each other. In England the crown is, generally speaking, entitled to all *bona piratorum*; but if any person can establish a title to the goods the claim of the crown thereto ceases. By 13 & 14 Vict. c. 26 (1850), ships and effects captured from pirates are to be restored on the payment of one-eighth of their value (by way of salvage), which is to be distributed among the recaptors.

Cowel (*Law Dict.*, 1727) states that in former times the word pirate was used in a better sense than that of a sea-robber, being attributed to persons to whose care the mole or pier of a haven was entrusted, and, quoting the learned Spelman, he adds, sometimes to a sea soldier: "Robertus vero Comes (Normaniæ) attemptavit venire in Angliam cum magno exercitu, sed a piratis Regis qui curam maris a Rege (Willielmo) susceperant repulsus est" (*Glossarium*, 1637, p. 460). (J. C. W.)

PIRÆUS. See ATHENS.

PIRANESI, GIOVANNI BATTISTA, an eminent Italian engraver of ancient architectural subjects, was born in the former half of the 18th century, and studied his art at Rome. The great remains of that city kindled his enthusiasm and demanded portrayal. His hand faithfully imitated the actual remains of a fabric; his invention, catching the design of the original architect, supplied the parts that were wanting; his skill introduced groups of vases, altars, tombs; and his broad and scientific distribution of light and shade completed the picture, and threw a striking effect over the whole. One engraving after another was executed with much brilliancy; and, as the work went on, the zeal of the artist only waxed stronger. In course of time it was found necessary to call in the aid of all his children and of several pupils. He did not, in fact, slacken in his exertions till his death in 1778. The plates of Piranesi, in which the severity of burin work is largely supplemented by the freer lines of the etching-needle, were collected and preserved by his son and coadjutor Francesco. They were published, to the number of about 2000, in 29 vols. fol., Paris, 1835-37.

PIRMASENS, a small manufacturing town of the Bavarian palatinate, lies in a hilly district, nearly 40 miles west by south of Spire. The staple industry is the production of boots and shoes, which are exported to Austria, Russia, and even America; but musical instruments, stoneware, and other articles are also manufactured. The only noteworthy buildings are the town-house and the principal church, the latter containing a fine monument to Louis IX., landgrave

of Hesse-Darmstadt. In 1880 the town contained 12,039 inhabitants, three-fourths of whom were Protestants.

Pirnassens owes its name to a St Pirmin, who is said to have preached Christianity here in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. In 1793 the Prussians gained a victory here over a body of French troops.

PIRMA, an ancient town of Saxony, lies on the left bank of the Elbe, on the margin of the "Saxon Switzerland," 11 miles above Dresden. It is on the whole a regularly built town, with promenades on the site of the former ramparts, but contains no notable edifices except the fine Gothic Hauptkirche (1502-46) and the town-house. The chief source of its prosperity is formed by the excellent sandstone found on both banks of the Elbe above the town; but manufactures of cigars, chemicals, enamelled tinware, pottery, and leather are also carried on. Besides the export of the sandstone, it transacts a trade in grain, fruit, and timber, mainly by river. The population in 1880 was 11,680, almost all Protestants.

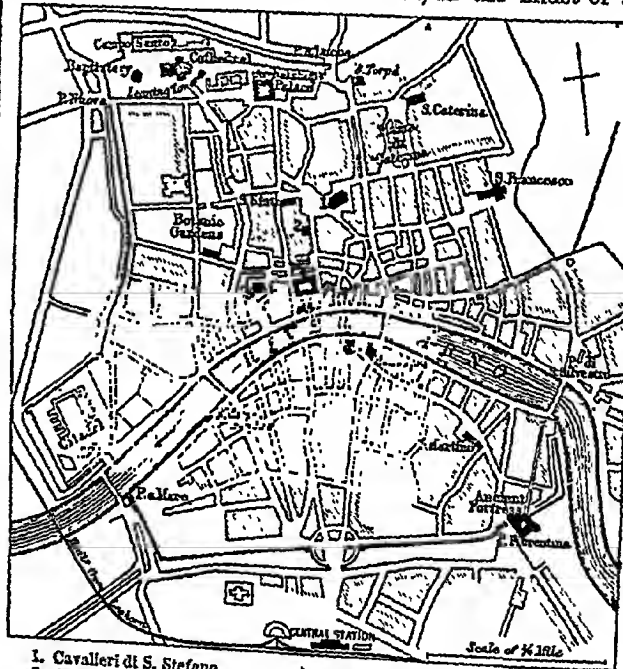

Pirna, originally a Slavonic settlement, long oscillated between Bohemia and Meissen (Saxony), but became permanently united with the latter in 1404. Having at a very early period received the privilege of holding fairs, it was at one time among the most flourishing of Saxon towns, but afterwards lost its importance through pestilence and the disasters of the Thirty Years' and Seven Years' Wars. On a rock above the town rises the fortress of Sonnenstein, now a lunatic asylum, erected in the 16th century on the site of an older castle, and once considered the most important fortress on the Elbe. It successfully withstood the Swedes in the Thirty Years' War, though the town was stormed, but was captured and dismantled by the Prussians in 1753. In 1813 it was occupied by the French, and held for several months.

PIRON, ALEXIS (1689-1773), the foremost epigrammatist of France, was born at Dijon on the 9th July 1689. His father, Aimé Piron, was an apothecary, but was also a frequent writer of verse in Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law without any success or much seriousness. As a young man he made himself notorious by the composition of a piece of licentious verse which might have brought him into serious difficulties but for the good nature of a high legal official, the president Bouhier. His sarcastic tongue made him unpopular in his neighbourhood, and at last in 1719, when nearly thirty years old, he went to seek his fortune at Paris. His first experiences were not very encouraging, and he had to put up with the unpleasant and not very honourable position of literary adviser and corrector to the Chevalier de Belle Isle. An accident, however, brought him money and notoriety. The jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage. None of the ordinary writers for this theatre, not even Lesage, would attempt a monologue-drama for the purpose, and Piron obtained a footing as a dramatic author, much applause, and three hundred crowns, with a piece called *Arlequin Deucalion*. Thenceforward he was constantly employed for this theatre, and not seldom for the more dignified Comédie Française, but with the exception of the excellent verse comedy of *La Métromanie* no one of his comedies and none of his tragedies at all deserve mention. His real vocation was that of an epigram maker, and this, though it made him not a few enemies, recommended him to not a few patrons who supplied his necessities. His most intimate associates, however, during the middle period of his life were two ladies of talent though not of position, Mademoiselle Quinault, the actress, and her friend Mademoiselle Quenauon or De Bar, companion to a lady of rank. She was slightly older than Piron and not beautiful, but after twenty years acquaintance he married her in 1741, lived happily enough with her for four years, and nursed her tenderly during an attack of madness which

in other two years proved fatal. He long outlived her, dying on the 21st January 1773 in his eighty-fourth year. The discredit of his early literary misdeed, and perhaps his indiscriminate habits of lampooning, prevented his election to the Academy, certain persons having induced the king to interpose his veto. But Piron was pensioned, and during the last half century of his life was never in any want. He was a complete literary free-lance, and lampooned Fréron and Desfontaines as sharply as he lampooned Voltaire and the *philosophe coterie*. Socially he was a rather loose liver, though probably, except on paper, not worse than most of his contemporaries. He was a member of the somewhat famous convivial society of the *Caveau*. But his true title to remembrance lies in his epigrams, one of which, the burlesque epitaph on himself but reflecting on the Academy (see vol. viii. p. 496), is known to almost everybody, while many others equal or surpass it in brilliancy. Grimm called him a "machine à saillies," and probably no man who ever lived possessed more of the peculiarly French faculty of sharply pointed verbal wit than he. It is noteworthy too that he was as ready with conversational retort as with his pen.

Piron published his own theatrical works in 1758, and after his death his friend and literary executor Rigolot de Juvigny published his *Œuvres Complètes*. During the last thirty years a good deal of unpublished work has been added by M. Bonhomme, Lalanne, and others. But the epigrams, which take up but little room and have been frequently reissued in various selections, are alone of great importance.

PISA, which has always been one of the most important cities of central Italy, is situated on the banks of the Arno at a short distance from the sea, in the midst of a

fertile plain backed by marble mountains wooded with pines and other forest trees. In the days of Strabo it was only two geographical miles from the sea-shore, but the continual increase of the delta at the mouth of the river has now trebled that distance. In the Middle Ages the Arno was still navigable for all ships of war then in use, and formed the safest of harbours.

The origin of Pisa is very ancient, and is involved in obscurity. The Romans believed it to date from the days of Troy, and also gave a legendary account of its foundation by colonists from Greece. Strabo mentions it as one of the bravest of the Etruscan cities. From Polybius we learn that in 225 B.C. it was already the friend of the Romans;

and later it became their ally and was defended by them from the ferocious onslaughts of the Ligurian and Apuan tribes. Thus the Romans acquired great power over the city, and finally subjected it to their rule. In Caesar's time according to some writers, in that of Augustus according to others, they established a military colony there. Nevertheless, excepting some inscriptions, sarcophagi, statues, and columns, very few remains of Roman buildings have been discovered in Pisa. Little is known of the history of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to regain its independence. Under the Byzantine dominion Pisa, like many other of the maritime cities of Italy, profited by the weakness of the Government at Constantinople to reassert its strength. And even during the first years of the harsh Lombard rule the need recognized by these oppressors of defending the Italian coast from the attacks of the Greeks was favourable to the development of the Pisan navy. Few particulars are extant concerning the real condition of the town; but we occasionally find Pisa mentioned, almost as though it were an independent city, at moments when Italy was overwhelmed by the greatest calamities. According to Amari's happy expression, "it was already independent by sea, while still enslaved on land." Its prosperity notably declined after the re-establishment of the Lombard rule and under the Franks. It again began to flourish under the marquises of Tuscany, who governed it in the name of the emperor.

In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the Middle Ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. And, although the numerous legends and fables of the old chroniclers disguise the true history of this struggle, they serve to attest the importance of Pisa in those days. In 1004 the Saracens forced the gates and sacked a quarter of the town; and in 1011 they renewed the attack. But the Pisans repulsed them and assumed the offensive in Calabria, Sicily, and even in Africa. Still more memorable was the expedition afterwards undertaken by the united forces of Pisa and Genoa against Mogâhid, better known in the Italian chronicles as Mugeto. This Moslem chief had made himself master of Sardinia, and was driven thence by the allied fleets in 1015. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native magistrates, who were like petty sovereigns, but were now subject to the sway of Pisa. This was the primary cause of the jealousy of the Genoese, and of the wars afterwards made by them upon Pisa and carried on until its power was crushed. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di Mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor Henry IV., that supplies the first authentic notice of the existence of consuls in mediæval Italy.<sup>1</sup> The oldest of Pisan statutes still extant is the *Breve dei Consoli di Mare* of 1162.

<sup>1</sup> It must be remembered that the Pisans and Florentines dated the beginning of the year *ab incarnatione*, i.e., from the 25th March. But the Florentines dated it from the 25th following and the Pisans from the 25th March preceding the commencement of the common year. The new or common style was adopted throughout Tuscany in the year 1750.

In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses, and privileges of all kinds in every Eastern port. Thus, while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese, and Moslems. In 1110 Pisa made peace with Lucca after six years of continuous hostilities. And between 1114 and 1116 it achieved a still greater enterprise. The Pisan fleet of three hundred sail, commanded by the archbishop Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Moslems, and returned loaded with spoil and with a multitude of Christian and Moslem prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. The chief eunuch who had governed Majorca perished in the siege. Immediately afterwards the fourteen years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor Lothair II., the Pisans entered the Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. It has been said that the copy of the Pandects then taken by the Pisans from Amalfi was the first known to them, but in fact they were already acquainted with those laws. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Moslems (1187) the Pisans and Genoese again met in conflict in the East, and performed many deeds of valour. They were always ready to come to blows, and gave still more signal proofs of their enmity during the Sicilian war in behalf of the emperor Henry VI. From that moment it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the erection of the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistery was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

It is asserted by some writers, especially by Tronci, that in the 12th century Pisa adopted a more democratic form of government. But in fact the chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelf and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. The independence of the former city was of much later origin,

only dating from the death of Countess Matilda (1115), but it rapidly rose to an ever-increasing power, and to inevitable rivalry with Pisa. Owing to the political and commercial interests binding Florence to the Roman court, the Gueft element naturally prevailed there, while the growth of its trade and commerce necessarily compelled that state to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a glorious resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a most ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog. This merely shows that there were already so many general and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched fifty-two galleys to assist Frederick II. in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia. The judges who governed the island were always at strife, and, as some of them applied to Pisa and some to Genoa for assistance against one another, the Italian seas were once more stained with blood, and the war burst out again and again, down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca, and all the Gueft cities of Tuscany against its Ghibelline rival. The pope had excommunicated Frederick II. and all his adherents. And, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia, and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now twelve elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of forty members. The rout of the Tuscan Guefts on the field of Montaperto (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstauffen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Gueft and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. The first man to step to the front at this moment was Count Ugolino della Gherardesca of the powerful house of that name. He had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the Guefts and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman Giovanni Visconti, judge of Gallura; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor to his party, his country, and his kin. So in 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid

waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms,—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino, whose houses they had burnt, and whose lands they had confiscated. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On the 6th August 1284 the great battle of Meloria took place. Here seventy-two Pisan galleys engaged eighty-eight Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She had lost her dominion over the sea, and the Tuscan Guefts again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters, he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca, and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi, and Gualandi, and a section of the popular party. The city was plunged into civil war. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After a day's fighting (1st July 1288) the count, his two sons, and his two nephews were captured in the Palazzo del Popolo (or town hall), and cast into a tower belonging to the Gualandi and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate, opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. Their own internal dissensions of 1293 put a stop to the campaign, but not before they had concluded an advantageous peace. They and all the members of the Gueft league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba they were exempted from every tax. They likewise received a ransom of 160,000 lire for their Pisan prisoners. These were no longer numerous, many having succumbed to the hardships and sufferings of all kinds to which they had been exposed.

In 1312 the arrival of the emperor Henry VII. gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Ugucione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown, he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on the 29th August 1315. So tyrannical, however, was his rule that in 1316 he was expelled by the popular

fury. But Pisa's freedom was for ever lost. He was succeeded by other lords or tyrants, of whom the most renowned was Castruccio Castracane, a political and military adventurer of much the same stamp as Uguccione himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them for ever; but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan, and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (2nd October), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then, in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Giovan Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa, and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son Gabriele Maria Visconti, who was afterwards expelled from its gates. But even during this century of disaster the Pisans continued to cherish the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Niccola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and Orcagna painted his celebrated frescos on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on the 9th October, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine Government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner

course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not hesitate, even in his presence, to assert their own independence, and, casting the Florentine ensign, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all their crops. Soderini, who was perpetual gonfalonier of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 the latter encamped his forces on three sides of the distressed city, which at last, reduced to extremity by famine, was forced to surrender on the 8th June 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions, which were freely distributed to all; they tried to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland, and the south of France, we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well-disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand-duke Cosmo I., a genuine statesman, not only restored the university, but instituted the "Uffizio dei Fossi," or drainage office for the reclamation of marsh lands, and founded the knighthood of St Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (see MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1595. These dreary times, however, are brightened by one glorious name—that of Galileo Galilei. A native of Pisa, he taught in its university; he made his first experiments in gravity from its bell tower, discovered, by observing the swing of the cathedral lamp, the law of the oscillation of the pendulum, and began there his stupendous reform of natural philosophy. But the sufferings inflicted on him by the Inquisition prove the depth of ignorance to which Tuscany and all Italy had then sunk.

As to Pisa, it is enough to mention that its population within the walls had been reduced in 1551 to 8574 souls, and that by 1745 it had only risen to the number of 12,406. Under the house of Lorraine, or more correctly during the reign of that enlightened reformer Pietro Leopoldo (1765–1790), Pisa shared in the general prosperity of Tuscany, and its population constantly increased. By 1840 it contained 21,670 souls, exclusive of the suburbs and outlying districts. At the present day Pisa is again one of the most flourishing cities of Tuscany. It counts 37,704 inhabitants within the walls, and in-

cluding the suburbs a total of 53,957. Its university is one of the best in Italy; it is an important railway centre; its commerce and manufactures are continually on the increase; its agriculture is rich and flourishing; and it is the chief city of a province numbering 283,563 inhabitants.

See P. Tronci, *Annali Pisani*, 2 vols., Pisa, 1863-1871; Roncioni, "Istoria Pisane," in the *Archivio Storico Italiano*, vol. vi. pt. 1; "Cronache Pisane," in the same *Archivio*, vol. vi. pt. 2; Repetti, *Dizionario Geografico Storico della Toscana*, s.v. "Pisa."

A few details regarding the principal buildings may be given by way of supplement to the foregoing article. The architects of the cathedral were Boschetto and Rinaldo, both Italians, probably Pisans. It is in plan a Latin cross, with an internal length of 311½ feet and a breadth of 252 feet. The nave, 109 feet high, has double vaulted aisles and the transepts single aisles; and at the intersection of nave and transepts there is a cupola. The basilica is still the predominant type, but the influence of the domed churches of Constantinople and the mosques of Palermo is also apparent. The pillars which support the nave are of marble from Elba and Giglio; those of the side aisles are the spoils of ancient Greek and Roman buildings brought by the Pisan galleys. Externally the finest part of the building is the west front, in which the note struck by the range of arches running round the base is repeated by four open arcades. Of the four doors three are by John of Bologna, who was greatly helped by Francavilla, Tacca, and others; that of the south side, of much older date, is generally supposed to be the work of Bonanno. Of the interior decorations it is enough to mention the altars of the nave, said to be after designs by Michelangelo, and the mosaics in the dome and the apse, which were among the latest designs of CIMABUE (q.v.). The baptistery was completed only in 1278, and marred in the 14th century by the introduction of Gothic details. The building is a circle 100 feet in diameter, and is covered with a cone-surmounted dome 190 feet high, on which stands a statue of St Raniero. The lowest range of semicircular arches consists of twenty columns and the second of sixty; and above this is a row of eighteen windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Niccola PISANO (q.v.). The campanile or "leaning tower of Pisa" is a round tower, the noblest, according to Freeman, of the southern Romanesque. Though the walls at the base are 13 feet thick, and at the top about half as much, they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by fifteen columns, and above this rise six arcades with thirty columns each. The eighth story, which contains the bells, is of much smaller diameter than the rest of the tower, and has only twelve columns. It is less the beauty of its architecture, great though that is, than to the fact that, being 11 feet 2 inches (or if the cornice be included 13 feet 8 inches) out of the perpendicular, it strikes the imagination in a way peculiarly its own. The entire height is 133 feet, but the ascent is easy by a stair in the wall, and the visitor hardly perceives the inclination till he reaches the top and from the lower edge of the gallery looks "down" along the shaft receding to its base. There is no reason to suppose that the architects, Bonanno and William of Innsbrück, intended that the campanile should be built in this oblique position; it would appear to have assumed it while the work was still in progress. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1183-1200), who made the spot peculiarly sacred by bringing fifty-three shiploads of earth from Mount Calvary. The building, erected in the Italian Gothic style between 1278 and 1283, by Giovanni Pisano, is of special interest chiefly for its famous fresco, noticed above (see also ORCAGNA, vol. xvii. p. 815).

PISA, LEONARDO OF. See PISANUS.

PISANELLO. See PISANO, VITTORE.

PISANO, ANDREA. Andrea da Pontadera (c. 1270-1313), generally known as Andrea Pisano, the chief pupil of GIOVANNI PISANO (q.v.), was born about 1270, and first learned the trade of a goldsmith, as did many other afterwards celebrated artists. This early training was of the greatest value to him in his works in bronze, to which the manipulation of the precious metals gave precision of design and refinement of execution. He became a pupil of Giovanni Pisano about 1300, and worked with him on the sculpture for S. Maria della Spina at Pisa and elsewhere. But it is at Florence that his chief works were executed, and the formation of his mature style was due rather to Giotto

than to his earlier master. Of the three world-famed bronze doors of the Florentine baptistery, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336.<sup>1</sup> This marvellous piece of bronze work, in many respects perhaps the finest the world has ever seen, has all the breadth of a sculptor's modelling, with the finish of a piece of gold jewellery. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues (see the figure), and the rest scenes from the

Part of the first bronze door of the Baptistery at Florence, by Andrea Pisano.

life of the Baptist. In design the panels owe much to Giotto: the composition of each is simple and harmonious, kept strictly within the due limits of the plastic art, no attempt at pictorial effects and varied planes being made,—in this very unlike the perhaps more magnificent but less truly artistic reliefs on the third door, that last executed by Ghiberti. Andrea Pisano, while living in Florence, also produced many important works of marble sculpture, all of which show strongly Giotto's influence. In some cases probably they were actually designed by that artist, as, for instance, the double band of beautiful panel-reliefs which Andrea executed for the great campanile. The subjects of these are the Four Great Prophets, the Seven Virtues, the Seven Sacraments, the Seven Works of Mercy, and the Seven Planets. The duomo contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect to the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The exact date of his death is not known, but it must have been shortly before the year 1349.

Andrea Pisano had two sons, Nino and Tommaso,—both, especially the former, sculptors of considerable ability. Nino was very successful in his statues of the Madonna and Child, which are full of human feeling and soft loveliness,—a perfect embodiment of the Catholic ideal of the Divine Mother. Andrea's chief pupil was Andrea di Cione, better known as ORCAGNA (q.v.). Balduccio di Pisa, another, and in one branch (that of sculpture) equally gifted pupil, executed the wonderful shrine of S. Eustorgio at Milan—a most magnificent mass of sculptured figures and reliefs.

PISANO, GIOVANNI (c. 1250-1330), son of NICCOLA PISANO (see below), born about 1250, was but little inferior to his father either as an architect or a sculptor. Together

<sup>1</sup> The date on the door, 1330, refers to the completion of the wax model, not of the casting, which was at first unsuccessful, and had to be done over again by Andrea himself.

with Arnolfo del Cambio and other pupils, he developed and extended into other parts of Italy the renaissance of sculpture which in the main was due to the extraordinary talent of that distinguished artist. After he had spent the first part of his life at home as a pupil and fellow-worker of Niccola, the younger Pisano was summoned between 1270 and 1274 to Naples, where he worked for Charles of Anjou on the Castel Nuovo. One of his earliest independent performances was the Campo Santo at Pisa, finished about 1283; along with this he executed various pieces of sculpture over the main door and inside the cloister. The richest in design of all his works (finished about 1286) is in the cathedral of Arezzo,—a magnificent marble high altar and reredos, adorned both in front and at the back with countless figures and reliefs—mostly illustrative of the lives of St Gregory and St Donato, whose bones are enshrined there. The actual execution of this was probably wholly the work of his pupils. In 1290 Giovanni was appointed architect or "capo maestro" of the new cathedral at Siena, in which office he succeeded Lorenzo Maitani, who went to Orvieto to build the less ambitious but equally magnificent duomo which had just been founded there. The design of the gorgeous façade of that duomo has been attributed to him, but it is more probable that he only carried out Maitani's design. According to Vasari, Giovanni and other pupils of Niccola also executed the bas-reliefs on the west front of Orvieto, but this assertion is unsupported by any documentary evidence. At Perugia, Giovanni built the church of S. Domenico in 1304, but little of the original structure remains. The north transept, however, still contains his beautiful tomb of Benedict XI, with a sleeping figure of the pope, guarded by angels who draw aside the curtain (see woodcut).

Part of the tomb of Benedict XI, by Giovanni Pisano.

Above is a sculptured plinth supporting canopied figures of the Madonna and other saints. The whole composition is framed by a high cusped and gabled arch, on twisted columns, enriched with glass mosaic in the style of the Cosmati. The general design is like the earlier tomb of Cardinal de Braye at Orvieto, the work of Giovanni's fellow-pupil, Arnolfo del Cambio.

One of Giovanni's most beautiful architectural works is the little chapel of S. Maria della Spina, on the banks of the Arno in Pisa; the actual execution of this gem-like chapel, and the sculpture with which it is adorned, was mostly the work of his pupils.<sup>1</sup> This exquisite little building has recently been pulled down and rebuilt, under the pretext of "restoration."

The influence of his father Niccola is seen strongly in all

Giovanni's works, but especially in the pulpit of S. Andrea at Pistoia, executed about 1300. In design it resembles that in the Pisan baptistery; but the reliefs are less severely classical, and more full of vivid dramatic power and complicated motives. Another pulpit, designed on the same lines, was made by him for the nave of Pisa cathedral between 1310 and 1311. Only fragments of this now exist, but it is in course of restoration. The last part of Giovanni's life was spent at Prato, near Florence, where with many pupils he worked at the cathedral till his death about 1330.

PISANO, NICCOLA (c. 1206–1278), one of the chief sculptors and architects of mediæval Italy, was born about 1206. Though he called himself *Pisanus*, from Pisa, where most of his life was spent, he was not a Pisan by birth. There are two distinct accounts of his parentage, both derived mainly from existing documents. According to one of these he is said to have been the son of "Petrus, a notary of Siena;" but this statement is very doubtful, especially as the word "Siena" or "de Senis" appears to be a conjectural addition. Another document among the archives of the Sienese cathedral calls him son of "Petrus de Apulia." Crowe and Cavalcaselle, as well as the majority of modern writers, accept the latter statement, and believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Those on the other hand who, with most of the older writers, prefer to accept the theory of Niccola's origin being Tuscan suppose that he was a native of a small town called Apulia near Lucca. As is the case with the biographies of so many of those artists who lived long before Vasari's own time, that author's account of Niccola is quite untrustworthy. There is no doubt that in the century preceding Niccola Pisano's birth Apulia, and the southern provinces generally, were more advanced in the plastic art than any part of northern Italy—witness especially the magnificent architecture and sculpture in the cathedrals of Salerno, Bari, Amalfi, Ravello, and many others, in which still exist bronze doors, marble pulpits, and other works of art of great merit, dating from the 11th and 12th centuries,—a period when northern Italy produced very little art-work of any real beauty. That the young Niccola Pisano saw and was influenced by these things cannot be denied, but Crowe and Cavalcaselle, in their eagerness to contradict the old traditions, go very much too far when they deny the story, told by Vasari, of Niccola's admiration for and keen study of the remains of ancient Roman sculpture which were then beginning to be sought for and appreciated. In Niccola Pisano's works it is somewhat difficult to trace the direct influence of Apulian art, while in many of them, especially the panel-reliefs of his Pisan pulpit (see figure), classical feeling is apparent in every fold of the drapery, in the modelling of the nude, and in the dignified reserve of the main lines of the composition.

For all that, Niccola was no dull copyist; though he emancipated himself from the stiffness and unreality of earlier sculpture, yet his admiration and knowledge of the physical beauty of the human form in no way detracted from the purity and religious spirit of his subjects. Though pagan in their beauty of modelling and grace of attitude, his Madonnas are as worshipful, and his saints as saintly, as those of any sculptor the world has ever seen. With true genius he opened out to the church a new field in which all the gifts of God, even purely physical ones, were made use of and adopted as types and symbols of inward purity and love—not repudiated and suppressed as snares of the evil one. Except through his works, but little is known of the history of Niccola's life. As early

<sup>1</sup> See Schultz, *Denkmäler der Kunst in Unter-Italien*, vol. vii. p. 5

as 1221 he is said to have been summoned to Naples by Frederick II, to do work in the new Castel dell' Uovo. This fact supports the theory of his southern origin, though not perhaps very strongly, as, some years before, the Pisan Bonannus had been chosen by the Norman king as the sculptor to cast one of the bronze doors for Monreale cathedral, where it still exists. The earliest existing piece of sculpture which can be attributed to Niccola is a beautiful relief of the Deposition from the Cross in the tympanum of the arch of a side door at San Martino at Lucca; it is remarkable for its graceful composition and delicate finish of execution. The date is about 1237. In 1260, as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is on the whole the finest of his works.

It is a high octagon, on semicircular arches, with trefoil cusps, supported by nine marble columns, three of which rest on white marble lions. In design it presents that curious combination of Gothic forms with classical details which is one of the characteristics of the medieval architecture of northern Italy; though much enriched with sculpture both in relief and in the round, the general lines of the design are not sacrificed to this, but the sculpture is kept subordinate to the whole. In this respect it is superior to the more magnificent pulpit at Siena, one of Niccola's later works, which suffers greatly from want of repose and purity of outline, owing to its being overloaded with reliefs and statuettes. Five of the sides of the main octagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion, and the Doom. These are all, especially the first three, works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccola's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the sweet yet stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccola's study of the antique is most apparent (see figure). The veiled and diademed figure of the Virgin Mother,

The Adoration of the Magi, one of the panels in the pulpit of the Pisan Baptistery, by Niccola Pisano.

seated on a throne, recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi. Certain figures in others of the panels are no less deeply imbued with classical feeling.

The next important work of Niccola in date is the Arca di San Domenico, in the church at Bologna consecrated to that saint, who died in 1221. Only the main part, the actual sarcophagus covered with sculptured reliefs of St. Dominic's life, is the work of Niccola and his pupils. The sculptured base and curved roof with its fanciful ornaments are later additions. This "Arca" was made when St. Dominic was canonized, and his bones translated; it was finished in 1267, not by Niccola himself, but by his pupils. The most magnificent, though not the most beautiful, of Niccola's works is the great pulpit in Siena cathedral (1268). It is much larger than that at Pisa, though somewhat similar in general design, being an octa-

gon on cusped arches and columns. Its stairs, and a large landing at the top, with carved balusters and panels, rich with semi-classical foliage, are an addition of about 1500. The pulpit itself is much overloaded with sculpture, and each relief is far too crowded with figures. An attempt to gain magnificence of effect has destroyed the dignified simplicity for which the earlier pulpit is so remarkable.

Niccola's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of basins rising one above another, each with sculptured bas-reliefs; it was begun in 1274, and completed, except the topmost basin, which is of bronze, by Niccola's son and pupil Giovanni.

Niccola Pisano was not only pre-eminent as a sculptor, but was also the greatest Italian architect of his century; he designed a number of very important buildings, though not all which are attributed to him by Vasari. Among those now existing, the chief are the main part of the cathedral at Pistoia, the church and convent of Sta Margherita at Cortona, and Sta Trinita at Florence. The church of Sant' Antonio at Padua has also been attributed to him, but without reason. Unfortunately his architectural works have in most cases been much altered and modernized. Niccola was also a skilled engineer, and was compelled by the Florentines to destroy the great tower, called the *Guarda-morto*, which overshadowed the baptistery at Florence, and had for long been the scene of violent conflicts between the Guelfs and Ghibellines. He managed skilfully so that it should fall without injuring the baptistery. Niccola Pisano died at Pisa in the year 1278, leaving his son Giovanni a worthy successor to his great talents both as an architect and sculptor.

Though his importance as a reviver of the old traditions of beauty in art has been to some extent exaggerated by Vasari, yet it is probable that he, more than any other one man, was the means of starting that "new birth" of the plastic arts which, in the years following his death, was so fertile in countless works of the most unrivalled beauty. Both Niccola and his son had many pupils of great artistic power, and these carried the influence of the Pisani throughout Tuscany and northern Italy, so that the whole art of the succeeding generations may be said to have owed the greater part of its rapid development to this one family.

On the three preceding Pisani see Perkins, *Tuscan Sculptors*, vol. I., 1864; Cicognara, *Storia della Scultura*, 1823-24; Gaye, *Kunstblatt*, 1839; Rümohr, *Italienische Forschungen*, 1827-31; Milanesi, *Documenti dell' Arte and Vita di Niccola Pisano*; Vasari, *Milanesi's ed.*, I. p. 293 and 481, 1882; Crowe and Cavalcaselle, *Painting in Italy*, 1864-66; Gruner, *Marmor-Bildwerke der Schule der Pisani*, 1858; Leader Scott, *Early Italian Sculptors*, 1882; Symonds, *Renaissance in Italy: Fine Arts*, p. 100 sq., 1877; Dohme, *Kunst und Künstler Italiens*, Leipzig, 1878; *Le tre porte del Battistero di Firenze*, 1821. (J. H. M.)

PISANO, VITTORE (c. 1380-1456), commonly called PISANELLO, the greatest of Italian medallists, was a native of San Vigilio sul Lago in the territory of Verona. Specimens of his work as a painter are still extant in Rome, Venice, Verona, and Pistoia, and entitle him to a place of some distinction in the history of that art. The National Gallery in London possesses a very fine specimen of Pisanello's work—a panel painted with miniature-like delicacy. For his pre-eminent position as a medallist, see NUMISMATICS, vol. xvii. p. 657. During the latter portion of his life he lived in Rome, where he enjoyed great repute.

PISANUS, LEONARDUS (Leonardo of Pisa), an Italian mathematician of the 13th century who has left the stamp of his name on a whole period in the history of the science. Of Leonardo's personal history few particulars are known. His father was called *Bonaccio*, most probably a nickname with the ironical meaning of "a good stupid fellow," while to Leonardo himself another nickname *Bigollone* (dunce, blockhead) seems to have been given. The father was secretary in one of the numerous factories erected on the southern and eastern coasts of the Mediterranean by the warlike and enterprising merchants of Pisa. Where European and Arab merchants met was at that time the right

place for learning arithmetic, and it was certainly with a view to this that the father had Leonardo sent to Bugia to continue his education. But Leonardo aimed at something higher than to make himself an accomplished clerk, and during his travels round the Mediterranean he obtained such erudition as would have gained him the name of a great scholar in much later times. In 1202 Leonardo Fibonacci (i.e., son of Bonaccio) was again in Italy and published his great work *Liber Abaci*, which probably procured him access to the learned and refined court of the emperor Frederick II. Leonardo certainly was in relation with some persons belonging to that circle, when he published in 1220 another more extensive work *De Practica Geometria*, which he dedicated to the imperial astronomer Dominicus Hispanus. Some years afterwards (perhaps in 1228, as is related by an author on the authority of a manuscript only once seen by him) Leonardo dedicated to another courtier, the well known astrologer Michael Scott, the second edition of his *Liber Abaci*, which has come down to our times, and has been printed as well as Leonardo's other works by Prince Bald. Boncompagni (Rome, 1857-62, 2 vols.). The other works consist of the *Practica Geometria* and some most striking papers of the greatest scientific importance, amongst which the *Liber Quadratorum* may be specially signalized. It bears the notice that the author wrote it in 1225, and in the introduction Leonardo himself tells us the occasion of its being written. Dominicus had presented Leonardo to Frederick II.<sup>1</sup> The presentation was accompanied by a kind of mathematical performance, in which Leonardo solved several hard problems proposed to him by John of Palermo, an imperial notary, whose name is met with in several documents dated between 1221 and 1240. The methods which Leonardo made use of in solving those problems fill the *Liber Quadratorum*, the *Flos*, and a *Letter to Magister Theodore*. All these treatises seem to have been written nearly at the same period, and certainly before the publication of the second edition of the *Liber Abaci*, in which the *Liber Quadratorum* is expressly mentioned. We know nothing of Leonardo's fate after he issued that second edition, and we might compare him to a meteor flashing up suddenly on the black background of the midnight sky, and vanishing as suddenly, were it not that his influence was too deep and lasting to allow of his being likened to a phenomenon passing quickly by.

To explain this influence and the whole importance of Leonardo's scientific work, we must rapidly sketch the state of mathematics about the year 1200. The Greeks, the most geometrical nation on the earth, had attained a high degree of scientific perfection, when they were obliged to yield to the political supremacy of Rome. From this time mathematics in Europe sunk lower and lower, till only some sorry fragments of the science were still preserved in the cell of the studious monk and behind the counting-board of the eager merchant. Geometry was nearly forgotten; arithmetic made use of the abacus with counters, or with the nine characters the origin of which is still a matter of controversy (see NUMERALS); the zero was still unknown. Among the Arabs it was quite otherwise. Greek mathematics found amongst them a second home, where the science was not only preserved but came to new strength, and was recruited from India, whence in particular came the symbol "zero" and its use, which alone renders possible numerical calculation in the modern sense of the word. Ancient astronomy as well as ancient mathematics reappeared in Europe, from the beginning of the 12th century onwards, in an Arabian dress. Two men especially recognized the worth of these sciences and made it the task of their life to propagate them amongst their

contemporaries,—the German monk Jordanus Nemorarius and the Italian merchant Leonardus Pisanus. Leonardo, as we have said, travelled all round the Mediterranean gathering knowledge of every kind. He studied the geometry of Euclid, the algebra of Mohammed ibn Musa Alcházim; he made himself acquainted with Indian methods; he found out by himself new theories. So runs his own account; and an exact comparison of Leonardo's works with older sources not only confirms the truth of his narrative, but shows also that he must have studied some other authors,—for instance, Alkarehi. In his *Practica Geometria* plain traces of the use of the Roman "agrimensores" are met with; in his *Liber Abaci* old Egyptian problems occur revealing their origin by the reappearance of the very numbers in which the problem is given, though one cannot guess through what channel they came to Leonardo's knowledge. Leonardo cannot now be regarded (as Cossali regarded him about 1800) as the inventor of that very great variety of truths for which he mentions no earlier source. But even were the predecessors to whom he is indebted more numerous than we are inclined to believe, were he the Columbus only of a territory the existence of which was unknown to his century, the historical importance of the man would be nearly the same. We must remember the general ignorance of his age, and then fancy the sudden appearance of a work like the *Liber Abaci*, which fills 459 printed pages. These pages set forth the most perfect methods of calculating with whole numbers and with fractions, practice, extraction of the square and cube roots, proportion, chain rule, finding of proportional parts, averages, progressions, even compound interest, just as in the completest mercantile arithmetics of our days. They teach further the solution of problems leading to equations of the first and second degree, to determinate and indeterminate equations, not by single and double position only, but by real algebra, proved by means of geometric constructions, and including the use of letters as symbols for known numbers, the unknown quantity being called *res* and its square *census*. We may well wonder, not that the impression caused by a work of such overwhelming character was so deep, but that it made any impression at all, and that the unprepared soil could receive the seed. The second work of Leonardo, his *Practica Geometria* (1220), is still more remarkable, since it requires readers already acquainted with Euclid's planimetry, who are able to follow rigorous demonstrations and feel the necessity for them. Among the contents of this book we simply mention a trigonometrical chapter, in which the words *sinus* versus *arcus* occur, the approximate extraction of cube roots shown more at large than in the *Liber Abaci*, and a very curious problem, which nobody would search for in a geometrical work, viz., to find a square number which remains a square number when 5 is added to it. This problem evidently suggested the first question put to our mathematician in presence of the emperor by John of Palermo, who, perhaps, was quite enough Leonardo's friend to set him such problems only as he had himself asked for. The problem was:—To find a square number remaining so after the addition as well as the subtraction of 5. Leonardo gave as solution the numbers  $11\frac{27}{25}$ ,  $16\frac{27}{25}$ , and  $6\frac{27}{25}$ —the squares of  $3\frac{3}{5}$ ,  $4\frac{3}{5}$ , and  $2\frac{3}{5}$ ; and the *Liber Quadratorum* gives the method of finding them, which we cannot discuss here. We observe, however, that the kind of problem was not new. Arabian authors already had found three square numbers of equal difference, but the difference itself had not been assigned in proposing the question. Leonardo's method, therefore, when the difference was a fixed condition of the problem, was necessarily very different from the Arabian, and, in all probability, was his own discovery. The *Flos* of Leonardo turns on the second question set by John of Palermo, which required the solution of the cubic equation  $x^3 + 2x^2 + 10x = 20$ . Leonardo, making use of fractions of the sexagesimal scale, gives  $x = 1^0 22' 7'' 42''' 33'' 4' 40''$ , after having demonstrated, by a discussion founded on the 10th book of Euclid, that a solution by square roots is impossible. It is much to be deplored that Leonardo does not give the least intimation how he found his approximative value, outrunning by this result more than three centuries. Genocchi believes Leonardo to have been in possession of a certain method called *regula aurea* by Cardan in the 16th century, but this is a mere hypothesis without solid foundation. In the *Flos* equations with negative values of the unknown quantity are also to be met with, and Leonardo perfectly understands the meaning of these negative solutions. In the *Letter to Magister Theodore* indeterminate problems are chiefly worked, and Leonardo hints at his being able to solve by a general method any problem of this kind not exceeding the first degree. We have enumerated the main substance of what appear to be Leonardo's own discoveries, and the experienced reader will not hesitate to conclude that they prove him to have been one of the greatest algebraists of any time. As for the influence he exercised on posterity, it is enough to say that Luca Pacioli, about 1500, in his celebrated *Summa*, leans so exclusively to Leonardo's works (at that time known in manuscript only) that he frankly acknowledges his dependence on them, and states that wherever no other author is quoted all belongs to Leonardus Pisanus. (M. CA.)

<sup>1</sup> The words "cum Magister Dominicus pedibus celsitudinis vestrae me Pisis duceret presentandum" have always been taken to mean that Leonardo was presented to the emperor at Pisa, but the date of 1225 excludes this interpretation, as Frederick II. certainly never was in Pisa before July 1226. The translation, therefore, ought to be—"when Magister Dominicus brought me from Pisa, &c.," the place where Leonardo met the emperor remaining unknown.

**PISCICULTURE.** This art as at present pursued is not limited to those animals which are grouped by zoologists in the class of *Pisces*. "Fishery" is now understood to signify the exploitation of all products of the sea, lake, and river, the capture of whales, turtles, pearls, corals, and sponges, as well as of fish proper. The purpose of fish-culture (or *aquiculture*, as it is in France more appropriately named) is to counteract by reparative and also by preventive measures the destructive effects of fishery.

The possibility of exterminating aquatic animals within the restricted limits of a lake or a river cannot be doubted; authorities are decidedly at variance, however, as to the extent of the influence of man upon the abundance of life in the open seas. Distinction must be made between the extermination of a species, even in a restricted locality, and the destruction of a fishery; the former is very unusual, and is seemingly impossible in the case of oceanic species, but the latter, especially for limited regions, is of almost yearly occurrence. Aquatic mammals, such as seals, may be entirely exterminated, especially when, like the fur seal, they forsake the water for a season and resort to the land for breeding purposes. The fur seals of the Pacific and Antarctic are now nearly gone, except in two groups of islands, the Pribylovs in Alaska and the Commander Islands in Siberia, where they enjoy Government protection, the islands being leased to the Alaska Commercial Company by whom only a stated number, all non-breeding males, may be killed each year, the permanence of the fishery being thus perfectly secured. Aquatic mammals also which never leave the water, like whales and sirenians, being conspicuous by reason of their size, and incapable of rapid multiplication, may, especially when they breed near the shore, suffer extermination. As examples may be cited the Arctic sea cow (*Rhytina stelleri*) and the Pacific grey whale (*Rhachianectes glaucus*), the former extinct, the latter having practically become so within the present century. The sperm whale is also rapidly disappearing. In the case of fixed animals like the oyster, the corals, and the sponges, again, the colonies or beds may be swept out of existence exactly as forests are hewn down. The native oyster beds of Europe are for the most part gone, and still more rapid has been the recent destruction of the oyster reefs in Pocomoke Sound, Maryland, a large estuary, formerly very productive—the result being due more directly to the choking up of the beds by the rubbish dragged over them by dredges, and the demolition of ledges suitable for the reception of young spat, than to the removal of all the adult oysters, which could, of course, never have been effected. The preservation of oyster-beds is a matter of vital importance to the United States, for oyster-fishing, unsupported by oyster-culture, will soon destroy the employment of tens of thousands and a cheap and favourite food of tens of millions of the people. Something may undoubtedly be effected by laws which shall allow each bed to rest for a period of years after each season of fishing upon it. It is, however, the general belief that shell-fish beds must be cultivated as carefully as are garden beds, and that this can be done only by giving to individuals rights in submerged lands, similar to those which may be acquired upon shore. It is probable that the present unregulated methods will prevail until the dredging of the natural beds shall cease to be remunerative, and that the oyster industry will then pass from the improvident fishermen to the painstaking oyster-grower, with a corresponding increase in price and decrease in consumption. Such a change has already taken place in France and Holland, and to a large extent in England, but there appear to be almost unsurmountable difficulties in the way of protecting the property of oyster-culturists from depredations—difficulties apparently as formidable in England as in America.

dations—difficulties apparently as formidable in England as in America.

Fishes in ponds, lakes, or streams are quickly exterminated unless the young be protected, the spawning season undisturbed, and wholesale methods of capture prohibited. Salmon and trout streams are preserved in all countries of northern Europe; and in Canada also a large service of fishery wardens is maintained. In the United States there are in many of the older commonwealths excellent codes of laws for the preservation of fish and game, which are enforced by anglers' clubs. A river may quickly be emptied of its anadromous visitors, salmon, shad, and alewives, by over-fishing in the spawning season, as well as by dams which cut off the fish from their spawning-grounds. Numerous rivers in Europe and America might be named in which this has occurred. In the same way, sea fishes approaching the coasts to spawn in the bays or upon the shoals may be embarrassed, and the numbers of each school decimated,—particularly if, as in the case of the herring, the eggs are adhesive and become entangled in nets. Sea fishes spawning in estuaries are affected much in the same manner as the salmon in rivers, though in a less degree, by wholesale capture in stationary nets. The shad and alewife fisheries of the United States are protected by an extensive code of laws, varying in the several States and in the different rivers of each State. The most satisfactory laws appear to be those which regulate the dates when fishery must commence and end, and prescribe at least one day in each week, usually Sunday, during which the ascent of the fish may not be interrupted. Migratory, semi-migratory, or wandering fishes, ranging singly or in schools over broad stretches of ocean, the mackerels, the tunnies, the sardines or pilchards, the menhaden, the bluefish, the bonitoes, and the squeeteague, stand apparently beyond the influence of human agency, especially since, so far as is known, they spawn at a distance from the coast, or since the adults, when about to spawn, cannot be reached by any kind of fishery apparatus. Their fecundity is almost beyond comprehension, and in many instances their eggs float free near the surface, and are quickly disseminated over broad areas. The conclusions gained by Prof. Baird, U.S. commissioner of fisheries, agree exactly with those of Prof. Huxley, that the number of any given kind of oceanic fish killed by man is perfectly insignificant when compared with the destruction effected by their natural enemies. Almost any body of water, be it a bay or sound, or be it the covering of a ledge or shoal at sea, may be over-fished to such a degree that fishing becomes unprofitable, especially if fishing be carried on in the spawning season. In this manner, no doubt, have the coasts of England been robbed of the formerly abundant supplies of turbot and sole.

The character of the various destructive influences which man brings to bear upon the inhabitants of the water and their effects having thus been briefly noticed, the student of fish culture is confronted by the question, What can be done to neutralize these destructive tendencies? There are evidently three things to do:—(1) to preserve fish waters, especially those inland, as nearly as it may be possible in their normal condition; (2) to prohibit wasteful or immoderate fishing; and (3) to put into practice the art of fish breeding—(a) to aid in maintaining a natural supply, (b) to repair the effects of past improvidences, and (c) to increase the supply beyond its natural limits rapidly enough to meet the necessities of a constantly increasing population.

The preservation of normal conditions in inland waters is comparatively simple. A reasonable system of forestry and water-purification is all that is required; and this is needed not only by the fish in the streams but by the

people living on the banks. It has been shown that a river which is too foul for fish to live in is not fit to flow near the habitations of man. Obstructions, such as dams, may, in most instances, be overcome by fish ladders. The salmon has profited much by those devices in Europe, and the immense dams in American rivers will doubtless be passable even for shad and alewives if the new system of fishway construction devised by Col. McDonald, and now being applied on the Savannah, James, and Potomac, and other large rivers, fulfils its present promises of success.<sup>1</sup>

The protection of fish by law is what legislators have been trying to effect for many centuries, and the success of their efforts must be admitted to have been very slight indeed. Great Britain has at present two schools of fishery-economists,—the one headed by Prof. Huxley, opposed to legislation, save for the preservation of fish in inland waters; the other, of which Dr Francis Day is the chief leader, advocating a strenuous legal regulation of sea fisheries also. Continental Europe is by tradition and belief committed to the last-named policy. In the United States, on the contrary, public opinion is generally antagonistic to fishery legislation; and Prof. Baird, the commissioner of fisheries, after carrying on for fourteen years, with the aid of a large staff of scientific specialists, investigations upon this very question, has not yet become satisfied that laws are necessary for the perpetuation of the sea fisheries, nor has he ever recommended to Congress the enactment of any kind of fishery laws.

Just here we meet the test problem in fish culture. Many of the most important commercial fisheries of the world, the cod fishery, the herring fishery, the sardine fishery, the shad and alewife fishery, the mullet fishery, the salmon fishery, the whitefish fishery, the smelt fishery, and many others, owe their existence to the fact that once a year these fishes gather together in closely swimming schools, to spawn in shallow water, on shoals, or in estuaries and rivers. There is a large school of quasi-economists who clamour for the complete prohibition of fishing during spawning time. Their demand demonstrates their ignorance. Deer, game, birds, and other land animals may easily be protected in the breeding season, and so may trout and other fishes of strictly local habits. Not so the anadromous and pelagic fishes. If they are not caught in the spawning-season, they cannot be caught at all.

The writer recently heard a prominent fish-culturist advocating before a committee of the United States Senate the view that shad should not be caught in the rivers because they come into the rivers to spawn. When asked what would become of the immense shad-fisheries if this were done, he ventured the remark that doubtless some ingenious person would invent a means of catching them at sea. The fallacy in the argument of these economists lies, in part, in supposing that it is more destructive to the progeny of a given fish to kill it when its eggs are nearly ripe than to kill the same fish eight or ten months earlier. We must not, however, ignore the counter-argument. Such is the mortality among fish that only an infinitesimal percentage attains to maturity. Professor Möbius has shown that for every grown oyster upon the beds of Schleswig-Holstein 1,045,000 have died. Only a very small percentage, perhaps not greater than this, of the shad or the smelt ever comes upon the breeding grounds. Some consideration, then, ought to be shown to those individuals which have escaped from their enemies and have come up to deposit the precious burden of eggs. How much must they be protected? Here the fish-culturist comes in with the proposition that "it is cheaper to

make fish so plentiful by artificial means that every fisherman may take all he can catch than to enforce a code of protection laws."

The salmon rivers of the Pacific slope of the United States, the shad rivers of the east, and the whitefish fisheries of the lakes are now so thoroughly under control by the fish-culturist that it is doubtful if any one will venture to contradict his assertion. The question is whether he can extend his domain to other species.

Fish-culture in a restricted sense must sooner or later be resorted to in all densely populated countries, for, with the utmost protection, nature unaided can do but little to meet the natural demand for fish to eat. Pond-culture (*Teichwirthschaft*), has been practised for many centuries, and the carp and the gold-fish have become domesticated like poultry and cattle. The culture of carp is an important industry in China and in Germany, though perhaps not more so than it was in England three and four centuries ago; the remains of ancient fish-stews may be seen upon almost every large estate in England, and particularly in the vicinity of old monasteries. Strangely enough, not a single well-conducted carp-pond exists in England to-day to perpetuate the memory of the tens of thousands which were formerly sustained, and the carp, escaping from cultivation, have reverted to a feral state and are of little value. Until improved varieties of carp are introduced from Germany, carp-culture can never be made to succeed in England. Carp-culture is rapidly coming into favour in the United States; a number of young scale carp and leather carp were imported in 1877 for breeding purposes, and the fish commission has since distributed them to at least 30,000 ponds. Two railway cars especially built for the purpose are employed during the autumn months delivering cargoes of carp, often making journeys of over three thousand miles, and special shipments have been made to Mexico and Brazil. The carp is not recommended as a substitute for the salmon, but is especially suited to regions remote from the sea where better-flavoured fish cannot be had in a fresh condition.

A kind of pond-culture appears to have been practised by the ancient Egyptians, though in that country as in ancient Greece and Rome, the practice seems to have been similar to that now employed in the lagoons of the Adriatic and of Greece, and to have consisted in driving the young fish of the sea into artificial enclosures or vivaria, when they were kept until they were large enough to be used.

The discovery of the art of artificially fecundating the ova of fish must apparently be accredited to Stephen Ludwig Jacobi of Hohenhausen in Westphalia, who, as early as 1748, carried on successful experiments in breeding salmon and trout. The importance of this discovery was thoroughly appreciated at the time, and from 1763 to 1800 was a fruitful subject of discussion in England, France, and Germany. George III. of England in 1771 granted to Jacobi a life pension. It has been claimed by many French writers that the process of artificial fecundation was discovered as early as 1420 by Dom Pinchon, a monk in the abbey of Reome, but this claim is but a feeble one, not having been advanced until 1854, and it is believed by many that the practice of the French monk was simply to collect and transplant the eggs which he had already found naturally fertilized. However interesting to the antiquarian, the proceedings of Dom Pinchon had no influence upon the progress of fish-culture. To Germany, beyond question, belongs the honour of discovering and carrying into practical usefulness the art of fish-culture. Upon the estate of Jacobi, by the discoverer and his sons, it was carried on as a branch of agriculture for fully eighty years—from 1741 to 1825—though it was nearly a hundred years before public opinion was

<sup>1</sup> Report of United States Fish Commission for 1883.

ripe for a general acceptance of its usefulness, a period during which its practice was never abandoned by the Germans.

Fish-culture in Britain was inaugurated in 1837 by Mr John Shaw, gamekeeper to the duke of Buccleuch at Dramlanrig, who, in the course of ichthyological investigations, had occasion to fecundate the eggs of salmon and rear the young; and, as regards France, an illiterate fisherman, Joseph Remy, living in the mountains of the Vosges, rediscovered, as it is claimed, or at any rate successfully practised, in association with Antoine Gehin, the culture of trout in 1842. The originality and practical influence of Remy and Gehin's work appear to have been exaggerated by French writers. On the other hand the establishment in 1850 at Huningue (Hünningen) in Alsace by the French Government of the first fish-breeding station, or "piscifactory," as it was named by Professor Coste, is of great significance, since it marks the beginning of public fish-culture. The art discovered in Germany was practised in Italy as early as 1791 by Baufalini; in France in 1820, in Bohemia in 1824, in Great Britain in 1837, in Switzerland in 1842, in Norway under Government patronage in 1850, in Finland in 1852, in the United States in 1853, in Belgium, Holland, and Russia in 1854, in Canada about 1863, in Austria in 1865, in Australasia, by the introduction of English salmon, in 1862, and in Japan in 1877.

*Artificial Propagation.*—Sponges have been successfully multiplied by cuttings, like plants, in Austria and in Florida. Oysters have long been raised in artificial enclosures from spat naturally deposited upon artificial stools. The eggs of the American and Portuguese oysters have been artificially fecundated and the young hatched, and in July 1883 Mr John A. Ryder, embryologist of the U.S. Fish Commission, solved the most difficult problem in American oyster-culture by completing a mechanical device for preventing the escape of the newly hatched oysters while swimming about prior to fixation.<sup>1</sup> The English oyster, being hermaphrodite, or monœcious, cannot be artificially propagated from the egg like the dioecious American species.

The fertilization of the fish egg is the simplest of processes, consisting, as every one knows, in simply pressing the ripe ova from the female fish into a shallow receptacle and then squeezing out the milt of the male upon them. Formerly a great deal of water was placed in the pan; now the "dry method," with only a little, discovered by the Russian Vrasski in 1854, is preferred. The eggs having been fertilized, the most difficult part of the task remains, namely, the care of the eggs until they are hatched, and the care of the young until they are able to care for themselves.

The apparatus employed is various in principle, to correspond to the physical peculiarities of the eggs. Fish-culturists divide eggs into four classes, viz.:—(1) heavy eggs, non-adhesive, whose specific gravity is so great that they will not float, such as the eggs of the salmon and trout; (2) heavy adhesive eggs, such as those of the herring, smelt, and perch; (3) semi-buoyant eggs, like those of the shad and whitefish (*Coregonus*); and (4) buoyant eggs, like those of the cod and mackerel. (1) Heavy non-adhesive eggs are placed in thin layers either upon gravel, grilles of glass, or sheets of wire cloth, in receptacles through which a current of water is constantly passing. There are numerous forms of apparatus for eggs of this class, but the most effective are those in which a number of trays of wire cloth, sufficiently deep to carry single layers of eggs, are placed one upon the other in a box or jar into which the water enters from below, passing out at the top. (2) Heavy adhesive eggs are received upon bunches of twigs or frames of glass plates to which they adhere, and which are placed in receptacles through which water is passing. (3) Semi-buoyant eggs, or those whose specific gravity is but slightly greater than that of the water, require altogether different treatment. They are necessarily placed together in large numbers, and to prevent their settling upon the bottom of the receptacle it is necessary to introduce a gentle current from below. For many years these eggs could be hatched only in floating receptacles with wire-cloth bottoms, placed at an angle to the current of the stream in which they were fixed, the motion of which was utilized to keep the eggs in suspension. Later an arrangement of plunging-buckets was invented, cylindrical receptacles with tops and bottoms of wire cloth, which were suspended in rows from beams worked up and down at the surface of the water by machinery. The eggs in the cylinders were thus kept

constantly in motion. Finally the device now most in favour was perfected; this is a receptacle, conical, or at least with a constricted termination, placed with its apex downward, through which passes from below a strong current, keeping the eggs constantly suspended and in motion. This form of apparatus, of which the M'Donald and Clark hatching-jars are the most perfect development, may be worked in connexion with any common hydrant.<sup>2</sup> (4) Floating eggs have been hatched only by means of rude contrivances for sustaining a lateral circular eddy of water in the receptacle.

The use of refrigerators, to retard the development of the eggs until such time as it is most convenient to take care of the fry, has been extensively introduced in the United States, and has been experimented upon in Germany.

The distinction between private and public fish-culture must be carefully observed. The maintenance of ponds for carp, trout, and other domesticated species is an industry to be classed with poultry-raising and bee-keeping, and its interest to the political economist is but slight. The proper function of public fish-culture is the stocking of the public waters with fish in which no individual can claim the right of property. This is being done in the rivers of the United States, with salmon, shad, and alewives, and in the lakes with whitefish. The use of steamships and steam machinery, the construction of refrigerating transportation cars, two of which, with a corps of trained experts, are constantly employed by the United States Fish Commission, moving fish and eggs from Maine to Texas, and from Maryland to California, and the maintenance of permanent hatching stations, seventeen in number, in different parts of the continent, are forms of activity only attainable by Government aid. Equally unattainable by private effort would be the enormous experiments in transplanting and acclimatizing fish in new waters,—such as the planting of Californian salmon in the rivers of the east, land-locked salmon and smelt in the lakes and rivers of the interior, and shad in California and the Mississippi valley, and the extensive acclimatization of German carp; the two last-named experiments carried out within a period of three years have met with successes beyond doubt, and are of the greatest importance to the country; the others have been more or less successful, though their results are not yet fully realized. It has been demonstrated, however, that the great river fisheries of the United States, which produced in 1880 48,000,000 lb of alewives, 18,000,000 lb of shad, 52,000,000 lb of salmon, besides bass, sturgeon, and smelt, and worth "at first hand" between 4,000,000 and 6,000,000 dollars, are entirely under the control of the fish-culturist to sustain or to destroy, and are capable of immense extension.

Having now attempted to define the field of modern fish-culture, and to show what it has already accomplished, it remains to be stated what appear to be its legitimate aims and limitations.

The aims of modern fish-culture, as understood by the present writer, are—(1) to arrive at a thorough knowledge of the life history from beginning to end of every species of economic value, the histories of the animals and plants upon which they feed or upon which their food is nourished, the histories of their enemies and friends, and the friends and foes of their enemies and friends, as well as the currents, temperatures, and other physical phenomena of the waters in relation to migration, reproduction, and growth; and (2) to apply this knowledge in such a practical manner that every form of fish shall be at least as thoroughly under control as are now the salmon, the shad, the alewife, the carp, and the whitefish. Its limitations are precisely those of scientific agriculture and animal rearing, since, although certain physical conditions may constantly intervene to thwart man's efforts in any given direction, it is quite within the bounds of reasonable expectation to be able to understand what these are, and how their effects are produced. An important consideration concerning the limitations of fish-culture must always be kept in mind in weighing the arguments for and against its success, viz., that effort towards the acclimatization of fishes in new waters is not fish-culture, but is simply one of the necessary experiments upon which fish-culture may be based. The introduction of carp from Germany to the United States was not fish-culture; it was an experiment; the experiment has succeeded, and fish-culture is now one of its results. The introduction of California salmon to the Atlantic slope was an experiment; it has not succeeded; its failure has nothing to do with the success of fish-culture. If any one wants to see successful fish-culture in connexion with this fish let him go to the Sacramento river. The introduction of shad to the Pacific coast was an experiment; it succeeded; shad culture can now be carried on without fear of failure by the Fish Commission of the Pacific States. An equally established success is whitefish culture in the Great Lakes. The experiments with cod and Spanish mackerel were not fish-culture, though it is hoped that they may yet lead up to it. And there is every reason to believe, from experiments in part completed, that the dominion of fish-culture may be extended in like manner to certain of the great sea fisheries, such as the cod, haddock, herring, mackerel, and Spanish mackerel fisheries.

<sup>1</sup> Bulletin, United States Fish Commission, 1883.

<sup>2</sup> Transactions, American Fish Cultural Association, 1883.

Public fish-culture exists only in the United States and Canada. European fish-culturists have always operated with only small numbers of eggs. The hatchery of Sir James Maitland at Howieton near Stirling, Scotland, may be specially mentioned in this connexion, since it is undoubtedly the finest private fish-cultural establishment in the world. It is described in one of the Conference papers of the International Fishery Exhibition.

The recent organization of the Scottish Fishery Board, and the establishment of a society for the biological investigation of the coasts of Great Britain, are indications that England, having at last recognized the importance of protecting its extensive fishery industries, will at no distant time become a leader in matters of fishery economy.

Holland, Germany, and Norway have hitherto been the only European nations manifesting intelligent enterprise in the consideration of fishery questions in general, although fair work has been done by Sweden and other countries in the treatment of limited special branches of this industry. In Germany the functions of the German Fishery Union (*Deutscher Fischerei-Verein*) and of the commission for the investigation of the German seas (*Ministerial-Kommission zur wissenschaftlichen Untersuchung der deutschen Meere zu Kiel*), taken together, represent practically the two divisions of the work of the United States Fish Commission,—propagation and investigation. The latter body is composed of a commission of scientific men, whose head is appointed by the Government; it is carried on with Government funds, but is not in any way subjected to Government control, the central headquarters being at Kiel instead of Berlin. The *Fischerei-Verein* is also a private body, under the patronage of the emperor, and with funds partly furnished by the Government and having also the general direction of the National Fish Cultural Society at Hünningen. This, also, is not a bureau of any Government department, but managed entirely by its own officers. It is the only European fisheries institution that has so far constituted a thoroughly successful experiment. The Netherlands Commission of Sea Fisheries (*Collegie voor de Zeevisserijen*) is a body of fifteen men, chiefly workers in science, occupying a responsible position in the national economy, their function being "to advise Government in all subjects connected with the interest of the fisheries." During the twenty-five years of its existence, says its historian, "the commission has constantly been consulted by Government on the different measures that might be beneficial, or on the abolition of others that were detrimental, to the fisheries." The Society for the Development of Norwegian Fisheries (*Selskabet for de Norske Fiskeriers Fremme*) is an organization independent of the Government, and electing its own officers, but receiving large grants from Government to carry on work precisely similar to that of the United States Commission. In 1882-83 these grants amounted to 49,000 kroner.

As an illustration of the interest manifested in fish-culture in the United States, it may be stated that from 1871 to 1883 \$1,190,955 has been appropriated by Congress for the use of the United States Fish Commission, and that thirty-five of the State Governments have made special grants for fish-culture, in the aggregate equal to \$1,101,000. To show the wholesale methods employed in this, a letter by Mr Livingston Stone, superintendent of one of the seventeen hatcheries supported by the United States Fish Commission, that on the McCloud river in California, may be quoted:—

"In the eleven years since the salmon-breeding station has been in operation 67,000,000 eggs have been taken, most of which have been distributed in the various States of the Union. Several millions, however, have been sent to foreign countries, including Germany, France, Great Britain, Denmark, Russia, Belgium, Holland, Canada, New Zealand, Australia, and the Sandwich Islands. About 15,000,000 have been hatched at the station, and the young fish placed in the McCloud and other tributaries of the Sacramento river. So great have been the benefits of this restocking of the Sacramento that the statistics of the salmon fisheries show that the annual salmon catch of the river has increased 5,000,000 pounds each year during the last few years."

Fifteen canneries now are fully supplied, whereas in 1872 the single establishment then on the river was obliged to close for lack of fish. In the two Government hatcheries at Alpena and Northville, Michigan, there have been produced in the winter of 1883-84 over 100,000,000 eggs of the whitefish, *Coregonus clupeaformis*, and the total number of young fish to be placed in the Great Lakes this year by these and the various State hatcheries will exceed 225,000,000. The fishermen of the Great Lakes admit that but for public fish-culture half of them would be obliged to abandon their calling. Instances of great improvement might be cited in connexion with nearly every shallow river in the United States. In the Potomac alone the annual yield has been brought up by the operations of fish-culture from 668,000 lb in 1877 to an average of more than 1,600,000 lb in recent years. In 1882 carp bred in the Fish Commission ponds in Washington were distributed in lots of 20 to 10,000 applicants throughout every State and Territory, at an average distance of more than 900 miles, the total mileage of the shipments being about 9,000,000 miles, and the actual distance traversed by the transportation car 34,000 miles. There still exists in Europe some scepticism as to the beneficial results of fish-culture. Such doubts do not exist on the other side of the Atlantic,

if the continuance from year to year of liberal grants of public money may be considered to be a test of public confidence.

Perhaps the best general treatises upon the methods of artificial propagation practised by pisciculturists are Herr Max Von Dem Borne's *Fischzucht*, Berlin, 1880, and from the philosophical standpoint, Dr Francis Day's *Fish Culture*, one of the handbooks of the International Fisheries Exhibition of 1883. The reports and bulletins of the United States Fish Commission, in twelve volumes, from 1873 to 1884, contain full descriptions of American methods, and discussions of all foreign discoveries and movements. Two prominent London journals, the *Field* and *Land and Water*, contain authoritative articles upon the subject, and the museum of fisheries and fish-culture at South Kensington, enriched as it has been by the contributions of exhibitors at the Fisheries Exhibition of 1883, is an excellent exponent of the methods and implements in use in the past and at present. For a history of the subject see "Epochs in the History of Fish Culture," by G. Brown Goode, in *Transactions of the American Fish Cultural Association* (10th meeting, 1881, pp. 34-58), and "The Status of the United States Fish Commission in 1881," by the same author, in part xii. of the *Report of that commission*; and for a discussion of modern methods and apparatus as shown at the late Fisheries Exhibition, the essays by Mr R. Edward Earle in the report of the United States commissioner to the exhibition and in *Nature* (Oct. 4, 1883). (G. B. G.)

PISEK, a small town of Bohemia, 55 miles to the south of Prague, lies on the right bank of the Wottawa, which is here crossed by an interesting stone bridge of great antiquity. The town generally has a mediæval air, heightened by the preservation of part of the old walls and bastions. The most prominent buildings are the church of the Nativity, the town-house, and the venerable chateau. The name of Pisek, which is the Czech for sand, is said to be derived from the gold-washing formerly carried on in the bed of the Wottawa. This source of profit, however, has been long extinct, and the inhabitants now support themselves by iron and brass founding, brewing, and the manufacture of shoes and Turkish fezes. The population in 1880 was 10,545.

Pisek was one of the chief centres of the Hussites, and it suffered very severely in the Thirty Years' War, when Maximilian of Bavaria put almost all the inhabitants to the sword. It was also occupied by the French in 1741. In spite of these reverses Pisek is now a very wealthy community, possessing large and valuable tracts of woodland.

PISIDIA, in ancient geography, was the name given to a country in the south of Asia Minor, immediately north of Pamphylia, by which it was separated from the Mediterranean, while it was bounded on the north by Phrygia, on the east by Isauria, Lycaonia, and Cilicia, and on the west and south-west by Lycia and a part of Phrygia (see vol. xv. Pl. II.). It was a rugged and mountainous district, comprising some of the loftiest portions of the great range of Mount Taurus, together with the offshoots of the same chain towards the central tableland of Phrygia. Such a region was naturally occupied from a very early period by wild and lawless races of mountaineers, who were very imperfectly reduced to subjection by the powers that successively established their dominion in Asia Minor. The Pisidians are not mentioned by Herodotus, either among the nations that were subdued by Croesus, or among those that furnished contingents to the army of Xerxes, and the first mention of them in history occurs in the *Anabasis* of Xenophon, when they furnished a pretext to the younger Cyrus for levying the army with which he designed to subvert his brother's throne, while he pretended only to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (*Anab.* i. 1, 11; ii. 1, 4, &c.). They are afterwards mentioned by Ephorus among the inland nations of Asia Minor, and assume a more prominent part in the history of Alexander the Great, to whose march through their country they opposed a determined resistance. In Strabo's time they had passed tranquilly under the Roman dominion, though still governed by their own petty chiefs and retaining to a considerable extent their predatory habits.

The boundaries of Pisidia, like those of most of the inland provinces or regions of Asia Minor, were not clearly defined, and appear to have fluctuated at different times. This was especially the case on the side of Lycia, where the upland district of Milyas was sometimes included in Pisidia, at other times assigned to Lycia. Some

writers, indeed, considered the Pisidians as the same people with the Milyans, while others regarded them as descendants of the Solymi, but Strabo speaks of the language of the Pisidians as distinct from that of the Solymi, as well as from that of the Lydians. The whole of Pisidia is an elevated region of tablelands or upland valleys in the midst of the ranges of Mount Taurus which descends abruptly on the side of Pamphylia. It contains several small lakes, but the only one of any importance is that now called the Egerdin Göl, of which the ancient name has not been preserved. It is a fresh-water lake of about 30 miles in length, situated in the north of Pisidia on the frontier of Phrygia, at an elevation of 2800 feet above the sea. The only rivers of any importance are the Cestrus and the Eurymedon, both of which take their rise in the highest ranges of Mount Taurus, and flow down through deep and narrow valleys to the plain of Pamphylia, which they traverse on their way to the sea.

Notwithstanding its rugged and mountainous character, Pisidia contained in ancient times several considerable towns, the ruins of which have been brought to light by the researches of recent travellers (Arundell, Hamilton, Daniell), and show them to have attained under the Roman empire to a degree of opulence and prosperity far beyond what we should have looked for in a country of predatory mountaineers. The most important of them are Termessus, near the frontier of Lycia, a strong fortress in a position of great natural strength and commanding one of the principal passes into Pamphylia; Cremna, another mountain fortress, north of the preceding, impending over the valley of the Cestrus; Sagalassus, a little farther north, a large town in a strong position, the ruins of which are among the most remarkable in Asia Minor; Selge, on the right bank of the Eurymedon, surrounded by rugged mountains, notwithstanding which it was in Strabo's time a large and opulent city; and Antioch, known for distinction's sake as Antioch in Pisidia, and celebrated for the visit of St Paul. This was situated in the extreme north-east of the district immediately on the frontier of Phrygia, between Lake Egerdin and the range of the Sultan Dag. Besides these there were situated in the rugged mountain tract west of the Cestrus Cretopolis, Olba or Olbasa, Fogla, Isinda, Etenna, and Conana. Pednelissus was in the upper valley of the Eurymedon above Selge. The only place in the district at the present day deserving to be called a town is Isbarta, the residence of a pasha; it stands at the northern foot of Mount Taurus, looking over the great plain which extends from thence into Phrygia. North of this and immediately on the borders of Phrygia stood Apollonia, called also Moridæum. Several other towns are assigned to Pisidia by Strabo, Pliny, and Ptolemy, of which the sites have not yet been determined.

We have no clue to the ethnic character and relations of the Pisidians, except that we learn from Strabo that they were distinct from the neighbouring Solymi, who were probably a Semitic race, but we find mention at an early period in these mountain districts of various other tribes, as the Cabali, Milyans, &c., of all which, as well as the neighbouring Isaurians and Lycaonians, the origin is wholly unknown, and in the absence of monuments of their language must, in all probability, ever remain so.

PISISTRATUS, citizen and afterwards tyrant of Athens, was the son of Hippocrates, through whom he traced his pedigree to Nelens and Nestor, princes of Messene in the Heroic Age. A branch of the family had reigned at Athens in the persons of Codrus and his descendants. Pisistratus was second cousin to Solon, their mothers having been cousins, and the early friendship between the two men was not entirely broken off even by

the wide political differences which separated them in later life. Pisistratus, who was much junior to Solon, was born about 605 B.C. In his youth there was a keen rivalry between Athens and Megara, and Pisistratus as general of Athens contrived by stratagem to defeat the Megarians and capture their port Nisæa (perhaps 570 or a little later).<sup>1</sup> But Pisistratus was ambitious of more than military triumphs, and in the internal condition of Attica he discerned the road to power. The constitution which Solon had given to Athens a few years before (594 B.C.) was too moderate to satisfy either of the extreme parties. The wealthy nobles chafed at the political rights granted to the lower classes, while the poor were dissatisfied with what they regarded as merely a half measure of relief. The nobles themselves were divided into the parties known as the Plain (*Pediæis*) and the Coast (*Paraloi*), the former inhabiting the western lowlands of Attica, the latter the level districts on the southern and eastern coasts.<sup>2</sup> The former were led by the noble Lycurgus, the latter by Megacles, of the proud house of the Alcmaeonidæ. Pisistratus took advantage of their dissensions to form a third political party out of the men of the Mountain (*Diacreis* or *Diacrioi*), the poor cottars and shepherds of the eastern and northern hills, among whom his own estates lay. He easily won the affection of these simple highlanders. His manners were captivating, his good humour imperturbable; his purse was ever at the service of the needy; his fields and gardens stood open for their enjoyment. Equality and fraternity, together with the maintenance of the constitution, were the watchwords of this eloquent and handsome aristocrat, the people's friend. But his easy and affable deportment hid a boundless ambition. Solon detected his schemes, and warned the people against him, but in vain. One day, not long after a violent dispute with Megacles in the public assembly, Pisistratus drove into the market-place, himself and his mules bleeding from wounds which he had inflicted with his own hand, but which he pretended to have received from his political enemies. The indignant people decreed a guard for the protection of their champion. Of this guard the champion soon availed himself in order to seize the Acropolis and make himself master of Athens (560). Megacles and the Alcmaeonidæ fled, but Solon remained and continued to lift his voice against the usurper, who, however, treated the old man with the utmost deference, as a valued friend and counsellor. Solon did not long survive his country's freedom; he died in the next year (559). The government of Pisistratus was marked by great moderation; he maintained the existing laws, to which he exacted obedience from all, and set the example of it himself. Being once accused of

<sup>1</sup> Herod., i. 59; Justin, ii. 8; Frontinus, iv. 7, 44. Other writers (Polyænus, i. 20; Ælian, *Var. Hist.*, vii. 19) erroneously attribute the stratagem to Solon, and refer it to the expedition in which Solon recovered Salamis. Plutarch (*Solon*, 8) falls into this mistake, and adds to it the blunder of representing Pisistratus as having taken part in the expedition, which happened about 600 B.C. The two events (Solon's conquest of Salamis and Pisistratus's capture of Salamis) are distinguished by Justin (ii. 7, 8), and after him by Duncker (*Gesch. des Alterthums*, vi. pp. 145, 244) and others, but they are confused by Thirlwall and Grote. From Plutarch (*Solon*, 8, 9) we may infer that the confusion arose in popular tradition. The account of the stratagem itself in the Greek writers Plutarch and Polyænus differs somewhat from that in the Latin writers Justin and Frontinus. Ælian follows (with some variations) the latter account.

<sup>2</sup> The difference between the *Pediæis* and the *Paraloi* seems to have been of the nature of a local feud between two ancient districts of Attica (Schol. on Aristoph., *Lys.*, 58; Strabo, ix. p. 392; Steph. Byz., s.v. *Διάρκεια*, *Πάραλος*, *πεδῖον*; Suidas, s.v. *Πάραλοι*) rather than a disagreement between two political parties. It is true that Plutarch mediates between the *Pediæis* (oligarchs) and the *Diacrioi* (democrats), but this has the appearance of being a mere conjecture of his own. His view is, however, accepted by Curtius and Duncker.

murder, he appeared in court like a private citizen to answer the charge, which, however, the accuser did not venture to press. But before he had time to establish himself firmly on the throne, he was expelled by a coalition of the Plain and Coast parties (perhaps in 555).<sup>1</sup> His property was confiscated and sold by auction. But after five or six years Megacles, unable to make head against the party of the Plain, proposed to Pisistratus to secure his recall on condition that Pisistratus should marry his daughter Cœsyra. Pisistratus agreed, and his return was effected by a stratagem. A tall and beautiful woman, Phya by name, was dressed as the goddess Athene, and drove into Athens on a chariot with Pisistratus at her side, while heralds proclaimed that Athene herself was bringing back Pisistratus. Thus restored, Pisistratus fulfilled his part of the bargain by marrying Cœsyra; but by his former marriage he had already sons approaching manhood (Hippias and Hipparchus), and he treated his young wife so slightly that Megacles, feeling himself affronted, made peace with his adversaries, and the united parties once more compelled Pisistratus to quit Athens (perhaps in 549). But he did not renounce his designs on the tyranny. The contributions which he received from various cities, especially Thebes, enabled him to hire a body of Argive mercenaries, with which he landed at Marathon in the eleventh year after his expulsion (perhaps in 538). His partisans flocked to him, and he defeated the Athenians at Pallene, and repossessed himself of the tyranny, which he thenceforward held till his death. He now placed his power on a securer basis by keeping a body of mercenaries in his pay, and levying a tax of a tenth or a twentieth on the produce of the soil. A further revenue accrued to him from the Thracian mines, and probably from the silver mines of Laurium, and the harbour and market dues. He now developed his plans for the extension of the naval empire of Athens in the Ægean. The island of Naxos was conquered by him, and handed over to Lygdamis, a native of the island, who had zealously supported the restoration of Pisistratus with men and money. In Naxos Pisistratus deposited the hostages he exacted from those of his enemies who chose to remain at Athens. In Sigeum on the Hellespont, which he conquered from the Mytilenians, he established as tyrant Hegesistratus, his son by an Argive wife, whom he had married in his second exile. The European side of the Hellespont was already in Athenian hands, Miltiades having established an Athenian colony on the Thracian Chersonese during the first tyranny, and with the consent of Pisistratus. Athens thus commanded the straits through which passed the corn trade of the Black Sea. Pisistratus further raised the reputation of Athens by purifying the sacred island of Delos; all the graves within sight of the temple of Apollo were opened and the dead removed to another part of the island. His rule was as wise and beneficent at home as it was glorious abroad. He encouraged agriculture by lending the poorer peasants cattle and seed, and he paid special attention to the cultivation of the olive. He enacted or enforced a law against idleness, and he required that the state should maintain its disabled soldiers. Under his rule and that of his sons Attica was intersected by high roads, which, converging to the capital, helped to unite the country and thus to abolish

local feuds and factions. To the tyrants Athens further owed those subterranean channels in the rock which still supply it with drinking water from the hills. Pisistratus also adorned Athens with splendid public buildings. The temple of the Pythian Apollo was his work; and he began, but did not finish, the great temple of Zeus, the remaining columns of which still astonish the beholder. Modern authorities<sup>2</sup> further ascribe to him the old Parthenon on the Acropolis, which was afterwards burned by the Persians and replaced by the Parthenon of Pericles. The Lyceum was attributed to him by Theopompus, but to Pericles by the better authority of Philochorus. He caused the Panathenaic festival to be celebrated every fourth year with unusual magnificence.

The well-known story that Pisistratus was the first to collect and publish the poems of Homer in their present form rests on the authority of late writers (Cicero being the earliest), and seems to be sufficiently disproved by the silence of all earlier authorities (see HOMER). The statement of Aulus Gellius that Pisistratus was the first to establish a public library at Athens is perhaps equally void of foundation. The tyrant seems to have been merciful and amiable to the last. It is not recorded of him that he ever put an enemy to death, and the easy good humour with which he submitted to affronts offered to himself and his family reminds us of Cæsar. Solon's description of him appears to have been justified—that apart from his ambition there was not a better-disposed man at Athens than Pisistratus. He died at an advanced age in 527, and was succeeded by his sons Hippias and Hipparchus (the Pisistratidæ), who continued to rule Athens in the same moderate and beneficent spirit. (J. G. FR.)

PISTACHIO NUT, see NUT, vol. xvii. p. 665. The pistachio nut is the species named in Gen. xliii. 11 (Heb. *תאנה*, Ar. *botm*) as forming part of the present which Joseph's brethren took with them from Canaan, and in Egypt it is still often placed along with sweetmeats and the like in presents of courtesy. The nut is used in various ways; but the simplest plan is to boil it with salt.

PISTOLA, or PISTOIA, a well-walled ancient city, 21 miles north-west of Florence, on a slight eminence near the Ombrone, one of the tributaries of the Arno; it now contains about 12,500 inhabitants. The chief manufacture of the place is iron-working, especially fire-arms.<sup>3</sup> It is on the site of the Roman *Pistoria*, of which little trace remains. During the Middle Ages Pistoia was at times a dangerous enemy to Florence, and the scene of constant conflicts between the Guelphs and the Ghibellines: it was there that, in the year 1300, the great party struggle took place which resulted in the creation of the Bianchi and Neri factions (see Dante, *Infer.*, xxiv., l. 121 to end). In the early development of architecture and sculpture Pistoia played a very important part; these arts, as they existed in Tuscany before the time of Niccola Pisano, can perhaps be better studied in Pistoia than anywhere else; nor is the city less rich in the later works produced by the school of sculptors founded by Niccola. In the 14th century Pistoia possessed a number of the most skilful artists in silver work, a wonderful specimen of whose powers exists now in the cathedral,—the great silver altar and frontal of St James, originally made for the high altar, but now placed in a chapel on the south side (see METAL WORK, vol. xvi. p. 65, fig. 4). The cathedral is partly of the 12th century, but rebuilt by one of the Pisani, and inside sadly modernized in the worst

<sup>1</sup> Out of the thirty-three years which elapsed between Pisistratus's first usurpation and his death in 527 B.C., we know (from Aristotle, *Pol.*, v. p. 1315 b) that he reigned during seventeen. He was twice deposed and banished, and his second exile lasted between ten and eleven years (Herod., i. 62); hence his first must have lasted between five and six. But we cannot fix with certainty the dates of these two exiles. Duncker (with whom Clinton, *Fasti Hellenici*, ii. p. 254, and Stein on Herod., i. 64, nearly agree) places the first in 555–550, and the second in 549–538 (see his *Gesch. d. Alterthums*, vi. p. 454 sq.).

<sup>2</sup> Curtius and Duncker in their histories of Greece; see also Wachsmuth, *Die Stadt Athen im Alterthum*, vol. i. p. 502.

<sup>3</sup> The word "pistol" is derived (apparently through *pistolese*, a dagger,—dagger and pistol being both small arms) from *Pistoia*, where that weapon was largely manufactured in the Middle Ages.

taste. Besides the silver altar it contains many fine works of sculpture; the chief are the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), and Verrocchio's finest work in marble, the monument to Cardinal Forteguerri (1474), with a large figure of Christ, surrounded by angels, in high relief. Unhappily two of the principal figures were destroyed not many years ago, and replaced by worthless modern ones.<sup>1</sup> Among the very early churches the principal is Sant' Andrea, enriched with sculpture, and probably designed, by Gruamons and his brother Adeodatus, in 1136; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches of almost equal interest are S. Giovanni Evangelista, also with sculpture by Gruamons, about 1160, and S. Bartolomeo in Pantano by the architect Rudolphus, 1167. S. Piero Maggiore and San Paolo are also churches begun in the 12th century. San Francesco al Prato is a fine church of the school of Niccola Pisano, end of the 13th century. San Domenico, a noble church built about 1380, contains the beautiful tomb of Filippo Lazari by Bernardo di Matteo, 1464. In addition to its fine churches, of which the above is a very incomplete list, Pistoia contains many noble palaces and public buildings. The Palazzo del Commune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century domestic architecture, in very good preservation. The Ospedale del Ceppo, built originally in the 13th century, but remodelled in the 15th, is very remarkable for the reliefs in enamelled and coloured terra-cotta with which its exterior is richly decorated. Besides various medallions, there is a frieze of figures in high relief extending along the whole front, over its open arcade. The reliefs consist of a series of groups representing the Seven Works of Mercy and other figures; these were executed by the younger members of the Della Robbia family between 1525 and 1535, and, though not equal to the best work of Luca and Andrea, are yet very fine in conception and modelling, and extremely rich in their general decorative effect.

PITCAIRN, or PITCAIRN'S ISLAND, an island of the eastern Pacific, in 25° 4' N. lat. and 130° 8' W. long., may be considered as a member or appendage of the Paumotu, Tuamotu, Low, or Dangerous Archipelago, but is nearly 100 miles south of Oeno. It is not more than 3 miles long from east to west and about 2 miles broad. Unlike the other islands of this region it has no coral reef, but rises abruptly from the depths with steep and rugged cliffs of dark basaltic lava. There is no anchorage except on a bank at the west end; and even the best of its three landing places—Bounty Bay on the north coast—is dangerous from the violence of the surf and the existence of a strong undertow. The longer axis of the island is formed by a range of steep hills, attaining in Outlook Ridge a maximum height of 1008 feet. On a plateau about 400 feet above the sea lies the village of Adamstown, with its fields and gardens. The climate is variable and rainy, and snow sometimes falls on the mountains; but, as there are no springs or streamlets, drinking water is apt to grow scarce in a dry season. Vegetation is luxuriant. Neither the bread fruit nor the cocoa nut, introduced by the settlers, are fully successful; but the sweet potato, which forms their staple food, banana, yam, taro, pineapple, &c., produce abundantly. Corn cannot be grown because of rats. The Pitcairn Islanders (not more than ninety in 1878), descended mainly from the mutineers of the "Bounty" and their Tahitian wives, are a healthy, virtuous, cheerful, and hospitable people, proud of their English

blood, and grateful for the services rendered them from time to time by the English Government and private liberality.

Stone axes, remains of sculptured stone pillars similar to those of Rapanui (Easter Island), and skeletons with a pearl-mussel beneath their head, have been found in the island, and show that, though it was uninhabited when discovered by Carteret in 1767, it had previously been occupied. Pitcairn was the name of the midshipman who first descried it from the mast-head. On 28th April 1789 a mutiny broke out on board the "Bounty," then employed by the English Government in conveying young bread-fruit trees from Tahiti to the West Indies. The commander, Lieutenant BLIGH (q.v.), was set adrift in the launch with a number of his officers and crew, but managed to make his way to Kupang in Timor (Dutch Indies). The mutineers, twenty-five in number, at first all returned to Tahiti. Of those who chose to be landed on that island, six were condemned to death by court-martial in England, and three of these were ultimately executed (1792). Two years earlier (1790) the other party (consisting of Fletcher Christian, the leader of the mutiny, eight other Englishmen, six Polynesian men, and twelve Polynesian women) had taken possession of Pitcairn and burned the "Bounty." The beautiful island, which might have been a paradise, was soon turned into a little hell. Treachery, drunkenness, madness, and murder fill the first years of its annals. By 1800 all the men were dead except Alexander Smith (afterwards known as John Adams), whose endeavours to train up the youthful generation thus left in his sole charge were crowned with success. An American vessel, the "Topaz," under Mayhew Folger, discovered the strange colony in 1805, and again, by accident, it was visited by the "Briton," Captain Sir F. Staines, and the "Tagus," Captain Pison, in 1817. On the death of John Adams, 29th March 1829, George Hann Nobbs, who, after an adventurous life had settled at Pitcairn in 1828, was appointed pastor and chief magistrate of the settlement. Through fear of drought the islanders, now numbering 87 persons, removed in 1830 to Tahiti, but neither the climate nor the morals of the place were such as they approved, and in 1831 they returned to their lonely island. Hardly had they settled into their old ways when Joshua Hill, a strange adventurer, rather crazy than criminal, appeared among them; claiming to be under Government authority, he tyrannized over them till his removal by an English man-of-war in 1838. In 1856 the whole population of Pitcairn—60 married persons and 134 young men, women, and children—were landed on NORFOLK ISLAND (q.v.); and the little island was again left to the occupancy of goats and cattle. In 1858, however, two men, William and Moses Young, chose to return with their families to their old homes, and their example was afterwards followed by a few others.

Brodie, *Pitcairn's Island*, 1854; T. B. Murray, *Pitcairn*, 1854; Menckel, *Die Insel Pitcairn*, 1853, and *Die Inseln des Stillen Oceans*, vol. II., 1876; and Lady Belcher, *The Mutineers of the "Bounty"*, 1870.

PITCAIRNE, ARCHBOLD (1652–1713), a distinguished Scottish physician, born at Edinburgh in 1652, and descended of an ancient Fifeshire family which barely escaped extinction at the battle of Flodden,—the proprietor of the estate and his seven sons having fallen in the battle, and the succession being only preserved by the birth of a posthumous child. After obtaining some classical education at the school of Dalkeith, Pitcairne entered Edinburgh university in 1668, and took his degree of M.A. in 1671. Like some men of great general ability, he seems to have remained long undetermined as to his future profession, and before taking to medicine he had made some progress first in divinity and then in law. But, having been sent to France for the benefit of his health, he was induced at Paris to begin the study of medicine. On his return to Scotland he applied himself for a time and with great success to the study of mathematics. Having at last taken vigorously to medicine, first at Edinburgh and afterwards for the second time at Paris, he obtained in 1680 his degree of M.D. from the faculty at Rheims. On returning to Scotland he at once began practice at Edinburgh, and in a short time acquired a great and wide reputation—so much so that in 1692 he was invited to fill a professor's chair at Leyden, and is said to have lectured there with great applause. Among his pupils were at least two men who afterwards rose to great eminence in their profession, Mead and Boerhaave, and both of them are understood to have attributed much of their skill to what they had learned from Pitcairne. In the following year

<sup>1</sup> One of the chief treasures of the S. Kensington Museum is the original sketch in clay for this monument, about 18 inches high,—now the only record of the original design of the two chief figures.

Pitcairne returned to Scotland to fulfil a matrimonial engagement with a daughter of Sir Archibald Stevenson, an eminent physician in Edinburgh; and, the family of the young lady having objected to their daughter going abroad, Pitcairne did not return to Leyden, but settled once more in Edinburgh, speedily acquired a most extensive practice, rose indeed to be the first physician of his time in Scotland, and was frequently called in as consulting physician not only in England but even in Holland.

Soon after his return to Edinburgh, feeling the great want of the means of anatomical study, he importuned the town council to permit himself and certain of his medical friends to dissect the bodies of paupers in "Paul's Work" unclaimed by their relations, and who therefore had hitherto been buried at the town's expense. They offered to attend them gratis when ill, and after dissection to bury them at their own charges. Strangely enough this proposal was strongly opposed by the chief surgeons of the place, but ultimately the town council had the good sense to comply with Pitcairne's request, and in this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine.

Though, according to Boerhaave, Pitcairne had not completely emancipated himself from some of the fanciful theories prevalent in his age in the science of medicine, yet the main characteristic of his superiority appears to have been that, like Sydenham and the higher class of physicians in England at that time, he insisted on strict adherence to the Baconian method of attending chiefly to facts of experience and observation. "Nothing," he remarks, "more hinders physic from being improved than the curiosity of searching into the natural causes of the effects of medicines. The business of men is to know the virtues of medicines, but to inquire whence they have that power is a superfluous amusement, since nature lies concealed. A physician ought therefore to apply himself to discover by experience the effects of medicines and diseases, and reduce his observations into maxims, and not needlessly fatigue himself by inquiring into their causes, which are neither possible nor necessary to be known. If all physicians would act thus we should not see physic divided into so many sects."

Pitcairne's medical opinions are chiefly contained in a volume of *Dissertations* which he published in 1701 (second and improved edition, 1713). In these he discusses the application of geometry to physic, the circulation of the blood in the smaller vessels, the difference in the quantity of the blood contained in the lungs of animals in the womb and of the same animals after birth, the motions by which food becomes fit to supply the blood, the question as to inventors in medicine (in which he repels the idea of certain medical discoveries of modern times having been known to the ancients, especially vindicating for Harvey the discovery of the circulation of the blood, and refuting the opinion of Dacier and others that it was known to Hippocrates), the cure of fevers by evacuating medicines, and the effects of acids and alkalis in medicine.

In addition to his great knowledge and skill as a physician, Pitcairne is understood to have been also an accomplished mathematician. He was intimate with the two Gregorys, and is said to have made some improvement on the method of infinite series invented by David Gregory. His strong addiction to mathematics seems to have misled him, along with some other eminent men of his time, into the idea of applying its methods of reasoning to subjects for which they are quite unfitted: in Pitcairne's case the attempt is made in one of his papers to adapt them to medicine.

He was also a very thorough classical scholar, and wrote

Latin verses, occasionally with something more than mere imitative cleverness and skill. Some verses of his on the death of Lord Dundee were translated by Dryden, and, as one of the latest editors of Dryden's poetry with perfect justice remarks, "the translation will not be thought so happy as the original."

According to the representations which are left by his contemporaries of his personal bearing and character, he seems to have carried his great faculties very lightly. "A strong man all round, with great animal spirits and jovial habits, somewhat contemptuous of the gravities and feebilities around him, a loudly avowed Jacobite and Episcopalian, rather reckless in his jests and sarcasms, and spending a good deal of his time in clubs, public houses, and drinking jollities, he was evidently regarded with little favour and some suspicion by the sober and decent Presbyterian circles of Edinburgh. "Drunk twice a day," according to the worthy, credulous, gossiping Wodrow (in one of his note books); "an unbeliever," "much given to profane jests," an "atheist," according to others. These reports may be taken for what they are worth, which perhaps is not very much. What is certain is that he was repeatedly involved in violent quarrels with his medical brethren and others, and once or twice got into scrapes with the Government on account of his indiscreet political utterances. Among his friends, however, he was evidently well liked, and he is known to have acted with great kindness and generosity to deserving men who needed his help. Ruddiman, the great Scottish scholar, for example, was rescued from a life of obscurity by his encouragement and assistance, and by no one was his memory more gratefully cherished.

"—Vale, lux Scotigenum, princepsque Medentum,  
Musarum columen deliciaeque, vale!"

are the concluding lines of a Latin epitaph by him on his venerated patron and friend, which still remains on Pitcairne's monument in the Greyfriars churchyard. Mead too, appears never to have forgotten what he owed to his old teacher at Leyden. A son of Pitcairne's had gone out in the rebellion of 1715, and, having been condemned to death was saved by the earnest interposition of Mead with Sir Robert Walpole. He pleaded, very artfully, that if Walpole's health had been bettered by his skill, or if members of the royal family were preserved by his care, it was owing to the instruction he had received from Dr Pitcairne. Pitcairne died in October 1713. Among his other scholarly tastes he had been a great collector of books, and his library, which is understood to have been of considerable value, was, through the influence of Ruddiman, disposed of to Peter the Great of Russia.

PITCH. See TAR.

PITCHER PLANTS. See INSECTIVOROUS PLANTS, vol. xiii. pp. 138, 139.

PITHOM, a city of Egypt, mentioned in Exod. i. 11, along with RAMESES (*q.v.*).

PITHOU, PIERRE (1539–1596), lawyer and scholar, was born at Troyes on November 1, 1539. His taste for literature was early seen, and his father, an advocate, cultivated it to the utmost. He first studied at Troyes, and afterwards went to Paris, where he completed his classical studies under Adrien Turnèbe and Pierre Galand. He next attended the lectures in law of Cujas at Bourges and Valence, and was called to the Paris bar in 1560. Here he achieved but little success as a pleader, but soon acquired a considerable practice as a consulting lawyer. On the outbreak of the second war of religion in 1567, Pithou, who was a Calvinist, withdrew to Sedan and afterwards to Basel, whence he returned to France on the publication of the edict of pacification. Soon afterwards he accompanied the

Duc de Montmorency on his embassy to England, returning shortly before the massacre of St Bartholomew, in which he narrowly escaped with his life. Next year he followed the example of Henry of Navarre, to whose cause he was ardently attached, by abjuring the Protestant faith. Henry, shortly after his own accession to the throne of France, recognized Pithou's talents and services by bestowing upon him various legal appointments. It was considerably after this date that Pithou achieved what was probably the most important work of his life, whether political or literary, by co-operating in the production of the powerful *Satire Menippée* (1593), which did so much to damage the cause of the League; the harangue of Daubray is usually attributed to his pen. He died at Nogent-sur-Seine on November 1, 1596. His valuable library, specially rich in MSS., was for the most part transferred to what is now the Bibliothèque Nationale in Paris.

Pithou wrote a great number of legal and historical books, besides preparing editions of several ancient authors. His earliest publication was *Adversarium Subsecivorum Lib. II.* (1565), which was highly praised by Turnèbe, Lipsius, and others. Perhaps his edition of the *Leges Visigothorum* (1579) was his most valuable contribution to historical science; in the same line he edited the *Capitula* of Charlemagne, Louis the Pious, and Charles the Bald in 1588, and he also assisted his brother François in preparing an edition of the *Corpus Juris Canonici* (1687). His essay *On the Gallican Liberties* (1594) is reprinted in his *Opera sacra juridica historica miscellanea collecta* (1609). In classical literature he was the first who made the world acquainted with the *Fables* of Phædrus (1598); he also edited the *Pervigilium Veneris* (1587), and Juvenal and Persius (1585).

**PITT, WILLIAM, FIRST EARL OF CHATHAM** See CHATHAM.

**PITT, WILLIAM** (1759–1806), the second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, daughter of Hester, Countess Temple, was born on the 28th of May 1759. The child inherited a name which, at the time of his birth, was the most illustrious in the civilized world, and was pronounced by every Englishman with pride, and by every enemy of England with mingled admiration and terror. During the first year of his life every month had its illuminations and bonfires, and every wind brought some messenger charged with joyful tidings and hostile standards. In Westphalia the English infantry won a great battle which arrested the armies of Louis XV. in the midst of a career of conquest; Boscawen defeated one French fleet on the coast of Portugal; Hawke put to flight another in the Bay of Biscay; Johnson took Niagara; Amherst took Ticonderoga; Wolfe died by the most enviable of deaths under the walls of Quebec; Clive destroyed a Dutch armament in the Hooghly, and established the English supremacy in Bengal; Coote routed Lally at Wandewash, and established the English supremacy in the Carnatic. The nation, while loudly applauding the successful warriors, considered them all, on sea and on land, in Europe, in America, and in Asia, merely as instruments which received their direction from one superior mind. It was the great William Pitt, the great commoner, who had vanquished the French marshals in Germany and French admirals on the Atlantic,—who had conquered for his country one great empire on the frozen shores of Ontario and another under the tropical sun near the mouths of the Ganges. It was not in the nature of things that popularity such as he at this time enjoyed should be permanent. That popularity had lost its gloss before his children were old enough to understand that their father was a great man. He was at length placed in situations in which neither his talents for administration nor his talents for debate appeared to the best advantage. The energy and decision which had eminently fitted him for the direction of war were not needed in time of peace. The lofty and spirit-stirring

eloquence which had made him supreme in the House of Commons often fell dead on the House of Lords. A cruel malady racked his joints, and left his joints only to fall on his nerves and on his brain. During the closing years of his life he was odious to the court, and yet was not on cordial terms with the great body of the Opposition. Chatham was only the ruin of Pitt, but an awful and majestic ruin, not to be contemplated by any man of sense and feeling without emotions resembling those which are excited by the remains of the Parthenon and of the Colosseum. In one respect the old statesman was eminently happy. Whatever might be the vicissitudes of his public life, he never failed to find peace and love by his own hearth. He loved all his children, and was loved by them; and of all his children the one of whom he was fondest and proudest was his second son.

The child's genius and ambition displayed themselves with a rare and almost unnatural precocity. At seven the hood-interest which he took in grave subjects, the ardour with which he pursued his studies, and the sense and vivacity of his remarks on books and on events amazed his parents and instructors. One of his sayings of this date was reported to his mother by his tutor. In August 1766, when the world was agitated by the news that Mr Pitt had become earl of Chatham, little William exclaimed, "I am glad that I am not the eldest son. I want to speak in the House of Commons like papa." A letter is extant in which Lady Chatham, a woman of considerable abilities, remarked to her lord that their younger son at twelve had left far behind him his elder brother, who was fifteen. "The fineness," she wrote, "of William's mind makes him enjoy with the greatest pleasure what would be above the reach of any other creature of his small age." At fourteen the lad was in intellect a man. Hayley, who met him at Lyme in the summer of 1773, was astonished, delighted, and somewhat overawed, by hearing wit and wisdom from so young a mouth. The poet, indeed, was afterwards sorry that his shyness had prevented him from submitting the plan of an extensive literary work, which he was then meditating, to the judgment of this extraordinary boy. The boy, indeed, had already written a tragedy, bad, of course, but not worse than the tragedies of his friend. This piece is still preserved at Chevening, and is in some respects highly curious. There is no love. The whole plot is political; and it is remarkable that the interest, such as it is, turns on a contest about a regency. On one side is a faithful servant of the crown, on the other an ambitious and unprincipled conspirator. At length the king, who had been missing, reappears, resumes his power, and rewards the faithful defender of his rights. A reader who should judge only by internal evidence would have no hesitation in pronouncing that the play was written by some Pittite poetaster at the time of the rejoicings for the recovery of George III. in 1789.

The pleasure with which William's parents observed the rapid development of his intellectual powers was alloyed by apprehensions about his health. He shot up alarmingly fast; he was often ill, and always weak; and it was feared that it would be impossible to rear a stripling so tall, so slender, and so feeble. Port wine was prescribed by his medical advisers; and it is said that he was, at fourteen, accustomed to take this agreeable physic in quantities which would, in our abstemious age, be thought much more than sufficient for any full-grown man. This regimen, though it would probably have killed ninety-nine boys out of a hundred, seems to have been well suited to the peculiarities of William's constitution; for at fifteen he ceased to be molested by disease, and, though never a strong man, continued, during many years of labour and anxiety, of nights passed in debate and of summers passed in London,

to be a tolerably healthy one. It was probably on account of the delicacy of his frame that he was not educated like other boys of the same rank. Almost all the eminent English statesmen and orators to whom he was afterwards opposed or allied—North, Fox, Shelburne, Windham, Grey, Wellesley, Grenville, Sheridan, Canning—went through the training of great public schools. Lord Chatham had himself been a distinguished Etonian; and it is seldom that a distinguished Etonian forgets his obligations to Eton. But William's infirmities required a vigilance and tenderness such as could be found only at home. He was therefore bred under the paternal roof. His studies were superintended by a clergyman named Wilson; and those studies, though often interrupted by illness, were prosecuted with extraordinary success. Before the lad had completed his fifteenth year his knowledge both of the ancient languages and of mathematics was such as very few men of eighteen then carried up to college. He was therefore sent, towards the close of the year 1773, to Pembroke Hall, in the university of Cambridge. So young a student required much more than the ordinary care which a college tutor bestows on undergraduates. The governor to whom the direction of William's academical life was confided was a bachelor of arts named Pretyman,<sup>1</sup> who had been senior wrangler in the preceding year, and who, though not a man of prepossessing appearance or brilliant parts, was eminently acute and laborious, a sound scholar, and an excellent geometrician. At Cambridge Pretyman was, during more than two years, the inseparable companion, and indeed almost the only companion, of his pupil. A close and lasting friendship sprang up between the pair. The disciple was able, before he completed his twenty-eighth year, to make his preceptor bishop of Lincoln and dean of St Paul's; and the preceptor showed his gratitude by writing a life of the disciple, which enjoys the distinction of being the worst biographical work of its size in the world.

Pitt, till he graduated, had scarcely one acquaintance, attended chapel regularly morning and evening, dined every day in hall, and never went to a single evening party. At seventeen he was admitted, after the bad fashion of those times, by right of birth, without any examination, to the degree of master of arts. But he continued during some years to reside at college, and to apply himself vigorously, under Pretyman's direction, to the studies of the place, while mixing freely in the best academic society. The stock of learning which Pitt laid in during this part of his life was certainly very extraordinary. In fact, it was all that he ever possessed; for he very early became too busy to have any spare time for books. The work in which he took the greatest delight was Newton's *Principia*. His liking for mathematics, indeed, amounted to a passion, which, in the opinion of his instructors, themselves distinguished mathematicians, required to be checked rather than encouraged. The acuteness and readiness with which he solved problems was pronounced by one of the ablest of the moderators, who in those days presided over the disputations in the schools and conducted the examinations of the senate-house, to be unrivalled in the university. Nor was the youth's proficiency in classical learning less remarkable. In one respect, indeed, he appeared to disadvantage when compared with even second-rate and third-rate men from public schools. He had never, while under Wilson's care, been in the habit of composing in the ancient languages; and he therefore never acquired that knack of

versification which is sometimes possessed by clever boys whose knowledge of the language and literature of Greece and Rome is very superficial. It would have been utterly out of his power to produce such charming elegiac lines as those in which Wellesley bade farewell to Eton, or such Virgilian hexameters as those in which Canning described the pilgrimage to Mecca. But it may be doubted whether any scholar has ever, at twenty, had a more solid and profound knowledge of the two great tongues of the old civilized world. The facility with which he penetrated the meaning of the most intricate sentences in the Attic writers astonished veteran critics. He had set his heart on being intimately acquainted with all the extant poetry of Greece, and was not satisfied till he had mastered Lycophron's *Cassandra*, the most obscure work in the whole range of ancient literature. This strange rhapsody, the difficulties of which have perplexed and repelled many excellent scholars, "he read," says his preceptor, "with an ease at first sight which, if I had not witnessed it, I should have thought beyond the compass of human intellect."

To modern literature Pitt paid comparatively little attention. He knew no living language except French; and French he knew very imperfectly. With a few of the best English writers he was intimate, particularly with Shakspeare and Milton. The debate in Pandemonium was, as it well deserved to be, one of his favourite passages; and his early friends used to talk, long after his death, of the just emphasis and the melodious cadence with which they had heard him recite the incomparable speech of Belial. He had indeed been carefully trained from infancy in the art of managing his voice, a voice naturally clear and deep-toned. His father, whose oratory owed no small part of its effect to that art, had been a most skilful and judicious instructor. At a later period the wits of Brookes's, irritated by observing, night after night, how powerfully Pitt's sonorous elocution fascinated the rows of country gentlemen, reproached him with having been "taught by his dad on a stool."

His education, indeed, was well adapted to form a great parliamentary speaker. One argument often urged against those classical studies which occupy so large a part of the early life of every gentleman bred in the south of our island is, that they prevent him from acquiring a command of his mother tongue, and that it is not unusual to meet with a youth of excellent parts, who writes Ciceronian Latin prose and Horatian Latin *alcaics*, but who would find it impossible to express his thoughts in pure, perspicuous, and forcible English. There may perhaps be some truth in this observation. But the classical studies of Pitt were carried on in a peculiar manner, and had the effect of enriching his English vocabulary, and of making him wonderfully expert in the art of constructing correct English sentences. His practice was to look over a page or two of a Greek or Latin author, to make himself master of the meaning, and then to read the passage straight forward into his own language. This practice, begun under his first teacher Wilson, was continued under Pretyman. It is not strange that a young man of great abilities, who had been exercised daily in this way during ten years, should have acquired an almost unrivalled power of putting his thoughts, without premeditation, into words well selected and well arranged.

Of all the remains of antiquity, the orations were those on which he bestowed the most minute examination. His favourite employment was to compare harangues on opposite sides of the same question, to analyse them, and to observe which of the arguments of the first speaker were refuted by the second, which were evaded, and which were left untouched. Nor was it only in books that he at this time studied the art of parliamentary fencing. When he

Subsequent studies at Cambridge.

[<sup>1</sup> George Pretyman (1750-1827) was senior wrangler in 1772. In 1803, on falling heir to a large estate, he assumed the name of Tomline. From Lincoln, to which see he had been elevated in 1787, he was translated to Winchester in 1820. Tomline, to whom Pitt when dying had bequeathed his papers, published his *Memoirs of the Life of William Pitt* (down to the close of 1792) in 1821 (3 vols. 8vo).]

was at home, he had frequent opportunities of hearing important debates at Westminster; and he heard them, not only with interest and enjoyment, but with a close scientific attention resembling that with which a diligent pupil at Guy's Hospital watches every turn of the hand of a great surgeon through a difficult operation. On one of these occasions Pitt, a youth whose abilities were as yet known only to his own family and to a small knot of college friends, was introduced on the steps of the throne in the House of Lords to Fox, who was his senior by eleven years, and who was already the greatest debater, and one of the greatest orators, that had appeared in England. Fox used afterwards to relate that, as the discussion proceeded, Pitt repeatedly turned to him, and said, "But surely, Mr Fox, that might be met thus;" or "Yes; but he lays himself open to this retort." What the particular criticisms were Fox had forgotten; but he said that he was much struck at the time by the precocity of a lad who, through the whole sitting, seemed to be thinking only how all the speeches on both sides could be answered.

One of the young man's visits to the House of Lords was a sad and memorable era in his life. He had not quite completed his nineteenth year when, on the 7th of April 1778, he attended his father to Westminster. A great debate was expected. It was known that France had recognized the independence of the United States. The duke of Richmond was about to declare his opinion that all thought of subjugating those states ought to be relinquished. Chatham had always maintained that the resistance of the colonies to the mother country was justifiable. But he conceived, very erroneously, that on the day on which their independence should be acknowledged the greatness of England would be at an end. Though sinking under the weight of years and infirmities, he determined, in spite of the entreaties of his family, to be in his place. His son supported him to a seat. The excitement and exertion were too much for the old man. In the very act of addressing the peers, he fell back in convulsions. A few weeks later his corpse was borne, with gloomy pomp, from the Painted Chamber to the Abbey. The favourite child and namesake of the deceased statesman followed the coffin as chief mourner, and saw it deposited in the transept where his own was destined to lie.

His elder brother, now earl of Chatham, had means sufficient, and barely sufficient, to support the dignity of the peerage. The other members of the family were poorly provided for. William had little more than three hundred a year. It was necessary for him to follow a profession. He had already begun to eat his terms. In the spring of 1780 he came of age. He then quitted Cambridge, was called to the bar, took chambers in Lincoln's Inn, and joined the western circuit. In the autumn of that year a general election took place; and he offered himself as a candidate for the university; but he was at the bottom of the poll. It is said that the grave doctors who then sat, robed in scarlet, on the benches of Golgotha thought it great presumption in so young a man to solicit so high a distinction. He was, however, at the request of a hereditary friend, the duke of Rutland, brought into parliament by Sir James Lowther for the borough of Appleby.

The dangers of the country were at that time such as might well have disturbed even a constant mind. Army after army had been sent in vain against the rebellious colonists of North America. On pitched fields of battle the advantage had been with the disciplined troops of the mother country. But it was not on pitched fields of battle that the event of such a contest could be decided. An armed nation, with hunger and the Atlantic for auxiliaries,

was not to be subjugated. Meanwhile the house of Bourbon, humbled to the dust a few years before by the genius and vigour of Chatham, had seized the opportunity of revenge. France and Spain had united against us, and had recently been joined by Holland. The command of the Mediterranean had been for a time lost. The British flag had been scarcely able to maintain itself in the British Channel. The northern powers professed neutrality; but their neutrality had a menacing aspect. In the East, Hyder had descended on the Carnatic, had destroyed the little army of Baillie, and had spread terror even to the ramparts of Fort St George. The discontents of Ireland threatened nothing less than civil war. In England the authority of the Government had sunk to the lowest point. The king and the House of Commons were alike unpopular. The cry for parliamentary reform was scarcely less loud and vehement than in the autumn of 1830. Formidable associations, headed, not by ordinary demagogues, but by men of high rank, stainless character, and distinguished ability, demanded a revision of the representative system. The populace, emboldened by the impotence and irresolution of the Government, had recently broken loose from all restraint, besieged the chambers of the legislature, hustled peers, hunted bishops, attacked the residences of ambassadors, opened prisons, burned and pulled down houses. London had presented during some days the aspect of a city taken by storm; and it had been necessary to form a camp among the trees of St James's Park.

In spite of dangers and difficulties abroad and at home, George III., with a firmness which had little affinity with virtue or with wisdom, persisted in his determination to put down the American rebels by force of arms; and his ministers submitted their judgment to his. Some of them were probably actuated merely by selfish cupidity; but their chief, Lord North, a man of high honour, amiable temper, winning manners, lively wit, and excellent talents both for business and for debate, must be acquitted of all sordid motives. He remained at a post from which he had long wished and had repeatedly tried to escape, only because he had not sufficient fortitude to resist the entreaties and reproaches of the king, who silenced all arguments by passionately asking whether any gentleman, any man of spirit, could have the heart to desert a kind master in the hour of extremity.

The Opposition consisted of two parties which had once been hostile to each other, and which had been very slowly and, as it soon appeared, very imperfectly reconciled, but which at this conjuncture seemed to act together with cordiality. The larger of these parties consisted of the great body of the Whig aristocracy. Its head was Charles, marquis of Rockingham, a man of sense and virtue, and in wealth and parliamentary interest equalled by very few of the English nobles, but afflicted with a nervous timidity which prevented him from taking a prominent part in debate. In the House of Commons the adherents of Rockingham were led by Fox, whose dissipated habits and ruined fortunes were the talk of the whole town, but whose commanding genius, and whose sweet, generous, and affectionate disposition, extorted the admiration and love of those who most lamented the errors of his private life. Burke, superior to Fox in largeness of comprehension, in extent of knowledge, and in splendour of imagination, but less skilled in that kind of logic and in that kind of rhetoric which convince and persuade great assemblies, was willing to be the lieutenant of a young chief who might have been his son.

A smaller section of the Opposition was composed of the old followers of Chatham. At their head was William, earl of Shelburne, distinguished both as a statesman and

as a lover of science and letters. With him were leagued Lord Camden, who had formerly held the great seal, and whose integrity, ability, and constitutional knowledge commanded the public respect; Barré, an eloquent and acrimonious declaimer; and Dunning, who had long held the first place at the English bar. It was to this party that Pitt was naturally attracted.

On the 26th of February 1781 he made his first speech in favour of Burke's plan of economical reform. Fox stood up at the same moment, but instantly gave way. The lofty yet animated deportment of the young member, his perfect self-possession, the readiness with which he replied to the orators who had preceded him, the silver tones of his voice, the perfect structure of his unpremeditated sentences, astonished and delighted his hearers. Burke, moved even to tears, exclaimed, "It is not a chip of the old block; it is the old block itself." "Pitt will be one of the first men in parliament," said a member of the opposition to Fox. "He is so already," answered Fox, in whose nature envy had no place. It is a curious fact, well remembered by some who were very recently living,<sup>1</sup> that soon after this debate Pitt's name was put up by Fox at Brookes's.

On two subsequent occasions during that session Pitt addressed the House, and on both fully sustained the reputation which he had acquired on his first appearance. In the summer, after the prorogation, he again went the western circuit, held several briefs, and acquitted himself in such a manner that he was highly complimented by Buller from the bench, and by Dunning at the bar.

On the 27th of November the parliament reassembled. Only forty-eight hours before had arrived tidings of the surrender of Cornwallis and his army; and it had consequently been necessary to rewrite the royal speech. Every man in the kingdom, except the king, was now convinced that it was mere madness to think of conquering the United States. In the debate on the report of the address, Pitt spoke with even more energy and brilliancy than on any former occasion. He was warmly applauded by his allies; but it was remarked that no person on his own side of the house was so loud in eulogy as Henry Dundas, the lord advocate of Scotland, who spoke from the ministerial ranks. That able and versatile politician distinctly foresaw the approaching downfall of the Government with which he was connected, and was preparing to make his own escape from the ruin. From that night dates his connexion with Pitt, a connexion which soon became a close intimacy, and which lasted till it was dissolved by death.

About a fortnight later Pitt spoke in the committee of supply on the army estimates. Symptoms of dissension had begun to appear on the treasury bench. Lord George Germaine, the secretary of state who was especially charged with the direction of the war in America, had held language not easily to be reconciled with declarations made by the first lord of the treasury. Pitt noticed the discrepancy with much force and keenness. Lord George and Lord North began to whisper together; and Welbore Ellis, an ancient placeman who had been drawing salary almost every quarter since the days of Henry Pelham, bent down between them to put in a word. Such interruptions sometimes discompose veteran speakers. Pitt stopped, and, looking at the group, said, with admirable readiness, "I shall wait till Nestor has composed the dispute between Agamemnon and Achilles."

After several defeats, or victories hardly to be distinguished from defeats, the ministry resigned. The king, reluctantly and ungraciously, consented to accept Rock-

ingham as first minister. Fox and Shelburne became secretaries of state. Lord John Cavendish, one of the most upright and honourable of men, was made chancellor of the exchequer. Thurlow, whose abilities and force of character had made him the dictator of the House of Lords, continued to hold the great seal.

To Pitt was offered, through Shelburne, the vice-treasurership of Ireland, one of the easiest and most highly paid places in the gift of the crown; but the offer was without hesitation declined. The young statesman had resolved to accept no post which did not entitle him to a seat in the cabinet; and a few days later he announced that resolution in the House of Commons. It must be remembered that the cabinet was then a much smaller and more select body than at present. We have seen cabinets of sixteen. In the time of our grandfathers a cabinet of ten or eleven was thought inconveniently large. Seven was a usual number. Even Burke, who had taken the lucrative office of paymaster, was not in the cabinet. Many therefore thought Pitt's declaration indecent. He himself was sorry that he had made it. The words, he said in private, had escaped him in the heat of speaking; and he had no sooner uttered them than he would have given the world to recall them. They, however, did him no harm with the public. The second William Pitt, it was said, had shown that he had inherited the spirit as well as the genius of the first. In the son, as in the father, there might perhaps be too much pride; but there was nothing low or sordid. It might be called arrogance in a young barrister, living in chambers on three hundred a year, to refuse a salary of five thousand a year, merely because he did not choose to bind himself to speak or vote for plans which he had no share in framing; but surely such arrogance was not very far removed from virtue.

Pitt gave a general support to the administration of Rockingham, but omitted, in the meantime, no opportunity of courting that ultra-Whig party which the persecution of Wilkes and the Middlesex election had called into existence, and which the disastrous events of the war, and the triumph of republican principles in America, had made formidable both in numbers and in temper. He supported a motion for shortening the duration of parliaments. He made a motion for a committee to examine into the state of the representation, and, in the speech by which that motion was introduced, avowed himself the enemy of the close boroughs, the strongholds of that corruption to which he attributed all the calamities of the nation, and which, as he phrased it in one of those exact and sonorous sentences of which he had a boundless command, had grown with the growth of England and strengthened with her strength, but had not diminished with her diminution or decayed with her decay. On this occasion he was supported by Fox. The motion was lost by only twenty votes in a house of more than three hundred members. The reformers never again had so good a division till the year 1831.

The new administration was strong in abilities, and was more popular than any administration which had held office since the first year of George III., but was hated by the king, hesitatingly supported by the Parliament, and torn by internal dissensions. The chancellor was disliked and distrusted by almost all his colleagues. The two secretaries of state regarded each other with no friendly feeling. The line between their departments had not been traced with precision; and there were consequently jealousies, encroachments, and complaints. It was all that Rockingham could do to keep the peace in his cabinet; and before the cabinet had existed three months Rockingham died.

In an instant all was confusion. The adherents of the

deceased statesman looked on the duke of Portland as their chief. The king placed Shelburne at the head of the treasury. Fox, Lord John Cavendish, and Burke immediately resigned their offices; and the new prime minister was left to constitute a Government out of very defective materials. His own parliamentary talents were great; but he could not be in the place where parliamentary talents were most needed. It was necessary to find some member of the House of Commons who could confront the great orators of the Opposition; and Pitt alone had the eloquence and the courage which were required. He was offered the great place of chancellor of the exchequer, and he accepted it. He had scarcely completed his twenty-third year.

The parliament was speedily prorogued. During the recess a negotiation for peace which had been commenced under Rockingham was brought to a successful termination. England acknowledged the independence of her revolted colonies; and she ceded to her European enemies some places in the Mediterranean and in the Gulf of Mexico. But the terms which she obtained were quite as advantageous and honourable as the events of the war entitled her to expect, or as she was likely to obtain by persevering in a contest against immense odds. All her vital parts, all the real sources of her power, remained uninjured. She preserved even her dignity; for she ceded to the house of Bourbon only part of what she had won from that house in previous wars. She retained her Indian empire undiminished; and, in spite of the mightiest efforts of two great monarchies, her flag still waved on the rock of Gibraltar. There is not the slightest reason to believe that Fox, if he had remained in office, would have hesitated one moment about concluding a treaty on such conditions. Unhappily that great and most amiable man was, at this crisis, hurried by his passions into an error which made his genius and his virtues, during a long course of years, almost useless to his country.

He saw that the great body of the House of Commons was divided into three parties—his own, that of North, and that of Shelburne; that none of these three parties was large enough to stand alone; that, therefore, unless two of them united there must be a miserably feeble administration, or, more probably, a rapid succession of miserably feeble administrations, and this at a time when a strong Government was essential to the prosperity and respectability of the nation. It was then necessary and right that there should be a coalition. To every possible coalition there were objections. But of all possible coalitions that to which there were the fewest objections was undoubtedly a coalition between Shelburne and Fox. It would have been generally applauded by the followers of both. It might have been made without any sacrifice of public principle on the part of either. Unhappily, recent bickerings had left in the mind of Fox a profound dislike and distrust of Shelburne. Pitt attempted to mediate, and was authorized to invite Fox to return to the service of the crown. "Is Lord Shelburne," said Fox, "to remain prime minister?" Pitt answered in the affirmative. "It is impossible that I can act under him," said Fox. "Then negotiation is at an end," said Pitt; "for I cannot betray him." Thus the two statesmen parted. They were never again in a private room together.

As Fox and his friends would not treat with Shelburne, nothing remained to them but to treat with North. That fatal coalition which is emphatically called "The Coalition" was formed. Not three quarters of a year had elapsed since Fox and Burke had threatened North with impeachment, and had described him night after night as the most arbitrary, the most corrupt, and the most incapable of ministers. They now allied themselves with him

for the purpose of driving from office a statesman with whom they cannot be said to have differed as to any important question. Nor had they even the prudence and the patience to wait for some occasion on which they might, without inconsistency, have combined with their old enemies in opposition to the Government. That nothing might be wanting to the scandal the great orators who had, during seven years, thundered against the war determined to join with the authors of that war in passing a vote of censure on the peace.

The parliament met before Christmas 1782. But it was not till January 1783 that the preliminary treaties were signed. On the 17th of February they were taken into consideration by the House of Commons. There had been, during some days, floating rumours that Fox and North had coalesced; and the debate indicated but too clearly that those rumours were not unfounded. Pitt was suffering from indisposition; he did not rise till his own strength and that of his hearers were exhausted; and he was consequently less successful than on any former occasion. His admirers owned that his speech was feeble and petulant. He so far forgot himself as to advise Sheridan to confine himself to amusing theatrical audiences. This ignoble sarcasm gave Sheridan an opportunity of retorting with great felicity. "After what I have seen and heard to-night," he said, "I really feel strongly tempted to venture on a competition with so great an artist as Ben Jonson, and to bring on the stage a second *Angry Boy*." On a division, the address proposed by the supporters of the Government was rejected by a majority of sixteen.

But Pitt was not a man to be disheartened by a single failure, or to be put down by the most lively repartee. When, a few days later, the Opposition proposed a resolution directly censuring the treaties, he spoke with an eloquence, energy, and dignity which raised his fame and popularity higher than ever. To the coalition of Fox and North he alluded in language which drew forth tumultuous applause from his followers. "If," he said, "this ill-omened and unnatural marriage be not yet consummated, I know of a just and lawful impediment; and, in the name of the public weal, I forbid the banns."

The ministers were again left in a minority, and Shelburne consequently tendered his resignation. It was accepted; but the king struggled long and hard before he submitted to the terms dictated by Fox, whose faults he detested, and whose high spirit and powerful intellect he detested still more. The first place at the board of treasury was repeatedly offered to Pitt; but the offer, though tempting, was steadfastly declined. The young man, whose judgment was as precocious as his eloquence, saw that his time was coming, but was not come, and was deaf to royal importunities and reproaches. His Majesty, bitterly complaining of Pitt's faintheartedness, tried to break the coalition. Every art of seduction was practised on North, but in vain. During several weeks the country remained without a Government. It was not till all devices had failed, and till the aspect of the House of Commons became threatening, that the king gave way. The duke of Portland was declared first lord of the treasury. Thurlow was dismissed. Fox and North became secretaries of state, with power ostensibly equal. But Fox was the real prime minister.

The year was far advanced before the new arrangements were completed; and nothing very important was done during the remainder of the session. Pitt, now seated on the Opposition bench, brought the question of parliamentary reform a second time under the consideration of the Commons. He proposed to add to the House at once a hundred county members and several members for metropolitan districts, and to enact that every borough of which

an election committee should report that the majority of voters appeared to be corrupt should lose the franchise. The motion was rejected by 293 votes to 149.

After the prorogation, Pitt visited the Continent for the first and last time. His travelling companion was one of his most intimate friends, a young man of his own age who had already distinguished himself in parliament by an engaging natural eloquence, set off by the sweetest and most exquisitely modulated of human voices, and whose affectionate heart, caressing manners, and brilliant wit made him the most delightful of companions, William Wilberforce. That was the time of Anglomania in France; and at Paris the son of the great Chatham was absolutely hunted by men of letters and women of fashion, and forced, much against his will, into political disputation. One remarkable saying which dropped from him during this tour has been preserved. A French gentleman expressed some surprise at the immense influence which Fox, a man of pleasure, ruined by the dice-box and the turf, exercised over the English nation. "You have not," said Pitt, "been under the wand of the magician."

State of  
parties,  
Nov.-  
Dec.  
1783.

In November 1783 the parliament met again. The Government had irresistible strength in the House of Commons, and seemed to be scarcely less strong in the House of Lords, but was, in truth, surrounded on every side by dangers. The king was impatiently waiting for the moment at which he could emancipate himself from a yoke which galled him so severely that he had more than once seriously thought of retiring to Hanover; and the king was scarcely more eager for a change than the nation. Fox and North had committed a fatal error. They ought to have known that coalitions between parties which have long been hostile can succeed only when the wish for coalition pervades the lower ranks of both. If the leaders unite before there is any disposition to union among the followers, the probability is that there will be a mutiny in both camps, and that the two revolted armies will make a truce with each other in order to be revenged on those by whom they think that they have been betrayed. Thus it was in 1783. At the beginning of that eventful year North had been the recognized head of the old Tory party, which, though for a moment prostrated by the disastrous issue of the American war, was still a great power in the state. To him the clergy, the universities, and that large body of country gentlemen whose rallying cry was "Church and King" had long looked up with respect and confidence. Fox had, on the other hand, been the idol of the Whigs, and of the whole body of Protestant dissenters. The coalition at once alienated the most zealous Tories from North and the most zealous Whigs from Fox. The university of Oxford, which had marked its approbation of North's orthodoxy by electing him chancellor, the city of London, which had been during two and twenty years at war with the court, were equally disgusted. Squires and rectors who had inherited the principles of the cavaliers of the preceding century could not forgive their old leader for combining with disloyal subjects in order to put a force on the sovereign. The members of the Bill of Rights Society and of the reform associations were enraged by learning that their favourite orator now called the great champion of tyranny and corruption his noble friend. Two great multitudes were at once left without any head, and both at once turned their eyes on Pitt. One party saw in him the only man who could rescue the king; the other saw in him the only man who could purify the parliament. He was supported on one side by Archbishop Markham, the preacher of divine right, and by Jenkinson, the captain of the praetorian band of the king's friends; on the other side by Jebb and Priestley, Sawbridge and Cartwright, Jack Wilkes and Horne Tooke. On the

benches of the House of Commons, however, the ranks of the ministerial majority were unbroken; and that any statesman would venture to brave such a majority was thought impossible. No prince of the Hanoverian line had ever, under any provocation, ventured to appeal from the representative body to the constituent body. The ministers, therefore, notwithstanding the sullen looks and muttered words of displeasure with which their suggestions were received in the closet, notwithstanding the roar of obloquy which was rising louder and louder every day from every corner of the island, thought themselves secure.

Such was their confidence in their strength that, as Fox's soon as the parliament had met, they brought forward a singularly bold and original plan for the government of the British territories in India. What was proposed was that the whole authority which till that time had been exercised over those territories by the East India Company should be transferred to seven commissioners, who were to be named by parliament, and were not to be removable at the pleasure of the crown. Earl Fitzwilliam, the most intimate personal friend of Fox, was to be chairman of this board, and the eldest son of North was to be one of the members.

As soon as the outlines of the scheme were known all the hatred which the coalition had excited burst forth with an astounding explosion. The question which ought undoubtedly to have been considered as paramount to every other was whether the proposed change was likely to be beneficial or injurious to the thirty millions of people who were subject to the company. But that question cannot be said to have been even seriously discussed. Burke, who, whether right or wrong in the conclusions to which he came, had at least the merit of looking at the subject in the right point of view, vainly reminded his hearers of that mighty population whose daily rice might depend on a vote of the British parliament. He spoke with even more than his wonted power of thought and language, about the desolation of Rohilcund, about the spoliation of Benares, about the evil policy which had suffered the tanks of the Carnatic to go to ruin; but he could scarcely obtain a hearing. The contending parties, to their shame it must be said, would listen to none but English topics. Out of doors the cry against the ministry was almost universal. Town and country were united. Corporations exclaimed against the violation of the charter of the greatest corporation in the realm. Tories and democrats joined in pronouncing the proposed board an unconstitutional body. It was to consist of Fox's nominees. The effect of his bill was to give, not to the crown, but to him personally, whether in office or in opposition, an enormous power, a patronage sufficient to counterbalance the patronage of the treasury and of the admiralty, and to decide the elections for fifty boroughs. He knew, it was said, that he was hateful alike to king and people; and he had devised a plan which would make him independent of both. Some nicknamed him Cromwell, and some Carlo Khan. Wilberforce, with his usual felicity of expression, and with very unusual bitterness of feeling, described the scheme as the genuine offspring of the coalition, as marked with the features of both its parents, the corruption of one and the violence of the other. In spite of all opposition, however, the bill was supported in every stage by great majorities, was rapidly passed, and was sent up to the Lords. To the general astonishment, when the second reading was moved in the Upper House, the Opposition proposed an adjournment, and carried it by eighty-seven votes to seventy-nine. The cause of this strange turn of fortune was soon known. Pitt's cousin, Earl Temple, had been in the royal closet, and had there

Pitt first  
lord

treasury  
and chan-  
cellor of  
the ex-  
chequer,  
Dec.  
1783.

been authorized to let it be known that His Majesty would consider all who voted for the bill as his enemies. The ignominious commission was performed, and instantly a troop of lords of the bedchamber, of bishops who wished to be translated, and of Scotch peers who wished to be re-elected made haste to change sides. On a later day the Lords rejected the bill. Fox and North were immediately directed to send their seals to the palace by their under secretaries; and Pitt was appointed first lord of the treasury and chancellor of the exchequer.

The general opinion was that there would be an immediate dissolution. But Pitt wisely determined to give the public feeling time to gather strength. On this point he differed from his kinsman Temple. The consequence was that Temple, who had been appointed one of the secretaries of state, resigned his office forty-eight hours after he had accepted it, and thus relieved the new Government from a great load of unpopularity; for all men of sense and honour, however strong might be their dislike of the India Bill, disapproved of the manner in which that bill had been thrown out. Temple carried away with him the scandal which the best friends of the new Government could not but lament. The fame of the young prime minister preserved its whiteness. He could declare with perfect truth that, if unconstitutional machinations had been employed, he had been no party to them.

He was, however, surrounded by difficulties and dangers. In the House of Lords, indeed, he had a majority; nor could any orator of the opposition in that assembly be considered as a match for Thurlow, who was now again chancellor, or for Camden, who cordially supported the son of his old friend Chatham. But in the other House there was not a single eminent speaker among the official men who sat round Pitt. His most useful assistant was Dundas, who, though he had not eloquence, had sense, knowledge, readiness, and boldness. On the opposite benches was a powerful majority, led by Fox, who was supported by Burke, North, and Sheridan. The heart of the young minister, stout as it was, almost died within him. He could not once close his eyes on the night which followed Temple's resignation. But, whatever his internal emotions might be, his language and deportment indicated nothing but unconquerable firmness and haughty confidence in his own powers. His contest against the House of Commons lasted from the 17th of December 1783 to the 8th of March 1784. In sixteen divisions the Opposition triumphed. Again and again the king was requested to dismiss his ministers; but he was determined to go to Germany rather than yield. Pitt's resolution never wavered. The cry of the nation in his favour became vehement and almost furious. Addresses assuring him of public support came up daily from every part of the kingdom. The freedom of the city of London was presented to him in a gold box. He went in state to receive this mark of distinction. He was sumptuously feasted in Grocers' Hall; and the shopkeepers of the Strand and Fleet Street illuminated their houses in his honour. These things could not but produce an effect within the walls of parliament. The ranks of the majority began to waver; a few passed over to the enemy; some skulked away; many were for capitulating while it was still possible to capitulate with the honours of war. Negotiations were opened with the view of forming an administration on a wide basis, but they had scarcely been opened when they were closed. The Opposition demanded, as a preliminary article of the treaty, that Pitt should resign the treasury; and with this demand Pitt steadfastly refused to comply. While the contest was raging, the clerkship of the Pells, a sinecure place for life, worth three thousand a year, and tenable with a seat in the House of Commons, became

vacant. The appointment was with the chancellor of the exchequer; nobody doubted that he would appoint himself, and nobody could have blamed him if he had done so; for such sinecure offices had always been defended on the ground that they enabled a few men of eminent abilities and small incomes to live without any profession, and to devote themselves to the service of the state. Pitt, in spite of the remonstrances of his friends, gave the Pells to his father's old adherent, Colonel Barré, a man distinguished by talent and eloquence, but poor and afflicted with blindness. By this arrangement a pension which the Rockingham administration had granted to Barré was saved to the public. Never was there a happier stroke of policy. About treaties, wars, expeditions, tariffs, budgets, there will always be room for dispute. The policy which is applauded by half the nation may be condemned by the other half. But pecuniary disinterestedness everybody comprehends. It is a great thing for a man who has only three hundred a year to be able to show that he considers three thousand a year as mere dirt beneath his feet, when compared with the public interest and the public esteem. Pitt had his reward. No minister was ever more rancorously libelled; but even when he was known to be overwhelmed with debt, when millions were passing through his hands, when the wealthiest magnates of the realm were soliciting him for marquises and garters, his bitterest enemies did not dare to accuse him of touching unlawful gain.

At length the hard-fought fight ended. A final remonstrance, drawn up by Burke with admirable skill, was carried on the 8th of March by a single vote in a full house. Had the experiment been repeated, the supporters of the coalition would probably have been in a minority. But the supplies had been voted; the Mutiny Bill had been passed; and the parliament was dissolved.

The popular constituent bodies all over the country were in general enthusiastic on the side of the new Government. A hundred and sixty of the supporters of the coalition lost their seats. The first lord of the treasury himself came in at the head of the poll for the university of Cambridge. His young friend, Wilberforce, was elected knight of the great shire of York, in opposition to the whole influence of the Fitzwilliams, Cavendishes, Duncans, and Saviles. In the midst of such triumphs Pitt completed his twenty-fifth year. He was now the greatest subject that England had seen during many generations. He domineered absolutely over the cabinet, and was the favourite at once of the sovereign, of the parliament, and of the nation. His father had never been so powerful, nor Walpole, nor Marlborough.

This narrative has now reached a point beyond which a full history of the life of Pitt would be a history of England, or rather of the whole civilized world; and for such a history this is not the proper place. Here a very slight sketch must suffice; and in that sketch prominence will be given to such points as may enable a reader who is already acquainted with the general course of events to form a just notion of the character of the man on whom so much depended.

If we wish to arrive at a correct judgment of Pitt's merits and defects, we must never forget that he belonged to a peculiar class of statesmen, and that he must be tried by a peculiar standard. It is not easy to compare him fairly with such men as Ximenes and Sully, Richelieu and Oxenstiern, John de Witt and Warren Hastings. The means by which those politicians governed great communities were of quite a different kind from those which Pitt was under the necessity of employing. Some talents, which they never had any opportunity of showing that they possessed, were developed in him to an extraordinary degree. In some qualities, on the other hand, to which they owe a large part of their fame, he was decidedly their inferior. They transacted business in their closets, or at boards where a few confidential councillors sat. It was his lot to be born in an age and in a country in which parliamentary government was completely established; his whole training from infancy was such as fitted him to bear a part in parliamentary government; and, from the prime of his manhood to his death, all the powers of his vigorous mind were almost constantly exerted in

the *Ethics*, of the man who thinks himself worthy of great things, being in truth worthy. It sprang from a consciousness of great powers and great virtues, and was never so conspicuously displayed as in the midst of difficulties and dangers which would have unnerved and bowed down any ordinary mind. It was closely connected, too, with an ambition which had no mixture of low cupidity. There was something noble in the cynical disdain with which the mighty minister scattered riches and titles to right and left among those who valued them, while he spurned them out of his way. Poor himself, he was surrounded by friends on whom he had bestowed three thousand, six thousand, ten thousand a year. Plain Mister himself, he had made more lords than any three ministers that had preceded him. The garter, for which the first dukes in the kingdom were contending, was repeatedly offered to him, and offered in vain.

Private  
life.

The correctness of his private life added much to the dignity of his public character. In the relations of son, brother, uncle, master, friend, his conduct was exemplary. In the small circle of his intimate associates he was amiable, affectionate, even playful. They loved him sincerely; they regretted him long; and they would hardly admit that he who was so kind and gentle with them could be stern and haughty with others. He indulged, indeed, somewhat too freely in wine, which he had early been directed to take as a medicine, and which use had made a necessary of life to him. But it was very seldom that any indication of undue excess could be detected in his tones or gestures; and, in truth, two bottles of port were little more to him than two dishes of tea. He had, when he was first introduced into the clubs of St James's Street, shown a strong taste for play; but he had the prudence and the resolution to stop before this taste had acquired the strength of habit. From the passion which generally exercises the most tyrannical dominion over the young he possessed an immunity, which is probably to be ascribed partly to his temperament and partly to his situation. His constitution was feeble; he was very shy; and he was very busy. The strictness of his morals furnished such buffoons as Peter Pindar and Captain Morris with an inexhaustible theme for merriment of no very delicate kind. But the great body of the middle class of Englishmen could not see the joke. They warmly praised the young statesman for commanding his passions, and for covering his frailties, if he had frailties, with decorous obscurity, and would have been very far indeed from thinking better of him if he had vindicated himself from the taunts of his enemies by taking under his protection a Nancy Parsous or a Marianne Clark.

Patron-  
age of  
letters  
and art.

No part of the immense popularity which Pitt long enjoyed is to be attributed to the eulogies of wits and poets. It might have been naturally expected that a man of genius, of learning, of taste, an orator whose diction was often compared to that of Tully, the representative, too, of a great university, would have taken a peculiar pleasure in befriending eminent writers to whatever political party they might have belonged. The love of literature had induced Augustus to heap benefits on Pompeians, Somers to be the protector of nonjurors, Harley to make the fortunes of Whigs. But it could not move Pitt to show any favour even to Pittites. He was doubtless right in thinking that, in general, poetry, history, and philosophy ought to be suffered, like calico and cutlery, to find their proper price in the market, and that to teach men of letters to look habitually to the state for their recompense is bad for the state and bad for letters. Assuredly nothing can be more absurd or mischievous than to waste the public money in bounties for the purpose of inducing people who ought to be weighing out grocery or measuring out drapery to write bad or middling books. But, though the sound rule is that authors should be left to be remunerated by their readers, there will, in every generation, be a few exceptions to this rule. To distinguish these special cases from the mass is an employment well worthy of the faculties of a great and accomplished ruler; and Pitt would assuredly have had little difficulty in finding such cases. While he was in power, the greatest philologist of the age, his own contemporary at Cambridge, was reduced to earn a livelihood by the lowest literary drudgery, and to spend in writing squibs for the *Morning Chronicle* years to which we might have owed an all but perfect text of the whole tragic and comic drama of Athens. The greatest historian of the age, forced by poverty to leave his country, completed his immortal work on the shores of Lake Lemn. The political heterodoxy of Porson and the religious heterodoxy of Gibbon may perhaps be pleaded in defence of the minister by whom those eminent men were neglected. But there were other cases in which no such excuse could be set up. Scarcely had Pitt obtained possession of unbounded power when an aged writer of the highest eminence, who had made very little by his writings, and who was sinking into the grave under a load of infirmities and sorrows, wanted five or six hundred pounds to enable him, during the winter or two which might still remain to him, to draw his breath more easily in the soft climate of Italy. Not a farthing was to be obtained; and before Christmas the author of the *English Dictionary* and of the *Lives of the Poets* had gasped his last in the

river fog and coal smoke of Fleet Street. A few months after the death of Johnson appeared the *Task*, incomparably the best poem that any Englishman then living had produced—a poem, too, which could hardly fail to excite in a well-constituted mind a feeling of esteem and compassion for the poet, a man of genius and virtue, whose means were scanty, and whom the most cruel of all the calamities incident to humanity had made incapable of supporting himself by vigorous and sustained exertion. Nowhere had Chatham been praised with more enthusiasm, or in verse more worthy of the subject, than in the *Task*. The son of Chatham, however, contented himself with reading and admiring the book, and left the author to starve. The pension which long after enabled poor Cowper to close his melancholy life unmolested by duns and bailiffs was obtained for him by the strenuous kindness of Lord Spencer. What a contrast between the way in which Pitt acted towards Johnson and the way in which Lord Grey acted towards his political enemy Scott, when Scott, worn out by misfortune and disease, was advised to try the effect of the Italian air! What a contrast between the way in which Pitt acted towards Cowper and the way in which Burke, a poor man and out of place, acted towards Crabbe! Even Dundas, who made no pretensions to literary taste, and was content to be considered as a hard-headed and somewhat coarse man of business, was, when compared with his eloquent and classically educated friend, a Mæccenas or a Leo. Dundas made Burns an exciseman, with seventy pounds a year; and this was more than Pitt, during his long tenure of power, did for the encouragement of letters. Even those who may think that it is, in general, no part of the duty of a Government to reward literary merit, will hardly deny that a Government which has much lucrative church preferment in its gift is bound, in distributing that preferment, not to overlook divines whose writings have rendered great service to the cause of religion. But it seems never to have occurred to Pitt that he lay under any such obligation. All the theological works of all the numerous bishops whom he made and translated are not, when put together, worth fifty pages of the *Horæ Paulinæ*, of the *Natural Theology*, or of the *View of the Evidences of Christianity*. But on Paley the all-powerful minister never bestowed the smallest benefice. Artists Pitt treated as contemptuously as writers. For painting he did simply nothing. Sculptors who had been selected to execute monuments voted by parliament had to haunt the ante-chambers of the treasury during many years before they could obtain a farthing from him. One of them, after vainly soliciting the minister for payment during fourteen years, had the courage to present a memorial to the king, and thus obtained tardy and ungracious justice. Architects it was absolutely necessary to employ; and the worst that could be found seem to have been employed. Not a single fine public building of any kind or in any style was erected during his long administration. It may be confidently affirmed that no ruler whose abilities and attainments would bear any comparison with his has ever shown such cold disdain for what is excellent in arts and letters.

His first administration lasted seventeen years. That long First period is divided by a strongly marked line into two almost exactly ministerial equal parts. The first part ended and the second began in the autumn of 1792. Throughout both parts Pitt displayed in the highest degree the talents of a parliamentary leader. During the first part he was a fortunate and in many respects a skilful administrator. With the difficulties which he had to encounter during the second part he was altogether incapable of contending; but his eloquence and his perfect mastery of the tactics of the House of Commons concealed his incapacity from the multitude.

The eight years which followed the general election of 1784 were First as tranquil and prosperous as any eight years in the whole history of England. Neighbouring nations which had lately been in arms 1784—against her, and which had flattered themselves that, in losing her American colonies, she had lost a chief source of her wealth and of her power, saw, with wonder and vexation, that she was more wealthy and more powerful than ever. Her trade increased. Her manufactures flourished. Her exchequer was full to overflowing. Very idle apprehensions were generally entertained that the public debt, though much less than a third of the debt which we now bear with ease, would be found too heavy for the strength of the nation. Those apprehensions might not perhaps have been easily quieted by reason. But Pitt quieted them by a juggle. He succeeded in persuading first himself and then the whole nation, his opponents included, that a new sinking fund, which, so far as it differed from former sinking funds, differed for the worse, would, by virtue of some mysterious power of propagation belonging to money, put into the pocket of the public creditor great sums not taken out of the pocket of the tax-payer. The country, terrified by a danger which was no danger, hailed with delight and boundless confidence a remedy which was no remedy. The minister was almost universally extolled as the greatest of financiers. Meanwhile both the branches of the house of Bourbon found that England was as formidable an antagonist as she had ever been. France had formed a plan for reducing Holland to vassalage. But England interposed, and France receded. Spain interrupted by

violence the trade of our merchants with the regions near the Oregon. But England armed, and Spain receded. Within the island there was profound tranquillity. The king was, for the first time, popular. During the twenty-three years which had followed his accession he had not been loved by his subjects. His domestic virtues were acknowledged. But it was generally thought that the good qualities by which he was distinguished in private life were wanting to his political character. As a sovereign he was resentful, unforgiving, stubborn, cunning. Under his rule the country had sustained cruel disgraces and disasters; and every one of those disgraces and disasters was imputed to his strong antipathies, and to his perverse obstinacy in the wrong. One statesman after another complained that he had been induced by royal caresses, entreaties, and promises to undertake the direction of affairs at a difficult conjuncture, and that as soon as he had, not without sullyng his fame and alienating his best friends, served the turn for which he was wanted, his ungrateful master began to intrigue against him and to canvass against him. Grenville, Rockingham, Chatham—men of widely different characters, but all three upright and high-spirited—agreed in thinking that the prince under whom they had successively held the highest place in the Government was one of the most insincere of mankind. His confidence was reposed, they said, not in those known and responsible counsellors to whom he had delivered the seals of office, but in secret advisers who stole up the back stairs into his closet. In parliament his ministers, while defending themselves against the attacks of the opposition in front, were perpetually, at his instigation, assailed on the flank or in the rear by a vile band of mercenaries who called themselves his friends. These men constantly, while in possession of lucrative places in his service, spoke and voted against bills which he had authorized the first lord of the treasury or the secretary of state to bring in. But from the day on which Pitt was placed at the head of affairs there was an end of secret influence. His haughty and inspiring spirit was not to be satisfied with the mere show of power. Any attempt to undermine him at court, any mutinous movement among his followers in the House of Commons, was certain to be at once put down. He had only to tender his resignation and he could dictate his own terms. For he, and he alone, stood between the king and the coalition. He was therefore little less than mayor of the palace. The nation loudly applauded the king for having the wisdom to repose entire confidence in so excellent a minister. His Majesty's private virtues now began to produce their full effect. He was generally regarded as the model of a respectable country gentleman, honest, good-natured, sober, religious. He rose early, he dined temperately, he was strictly faithful to his wife, he never missed church, and at church he never missed a response. His people heartily prayed that he might long reign over them; and they prayed the more heartily because his virtues were set off to the best advantage by the vices and follies of the prince of Wales, who lived in close intimacy with the chiefs of the Opposition.

The regency, 1788. How strong this feeling was in the public mind appeared signally on one great occasion. In the autumn of 1788 the king became insane. The Opposition, eager for office, committed the great indiscretion of asserting that the heir apparent had, by the fundamental laws of England, a right to be regent with the full powers of royalty. Pitt, on the other hand, maintained it to be the constitutional doctrine that when a sovereign is, by reason of infancy, disease, or absence, incapable of exercising the regal functions, it belongs to the estates of the realm to determine who shall be the viceregent, and with what portion of the executive authority such viceregent shall be entrusted. A long and violent contest followed, in which Pitt was supported by the great body of the people with as much enthusiasm as during the first months of his administration. Tories with one voice applauded him for defending the sick-bed of a virtuous and unhappy sovereign against a disloyal faction and an undutiful son. Not a few Whigs applauded him for asserting the authority of parliaments, and the principles of the Revolution, in opposition to a doctrine which seemed to have too much affinity with the servile theory of indefeasible hereditary right. The middle class, always zealous on the side of decency and the domestic virtues, looked forward with dismay to a reign resembling that of Charles II. The palace, which had now been, during thirty years, the pattern of an English home, would be a public nuisance, a school of profligacy. To the good king's repast of mutton and lemonade, despatched at three o'clock, would succeed midnight banquets, from which the guests would be carried home speechless. To the backgammon board at which the good king played for a little silver with his equerries would succeed faro tables from which young patricians who had sat down rich would rise up beggars. The drawing-room, from which the frown of the queen had repelled a whole generation of frail beauties, would now be again what it had been in the days of Barbara Palmer and Louisa de Querouville. Nay, severely as the public reprobated the prince's many illicit attachments, his one virtuous attachment was reprobated more severely still. Even in grave and pious circles his Protestant mistresses gave less scandal than his Popish wife. That he must

be regent nobody ventured to deny. But he and his friends were so unpopular that Pitt could, with general approbation, propose to limit the powers of the regent by restrictions to which it would have been impossible to subject a prince beloved and trusted by the country. Some interested men, fully expecting a change of administration, went over to the Opposition. But the majority, purified by these desertions, closed its ranks, and presented a more firm array than ever to the enemy. In every division Pitt was victorious. When at length, after a stormy interregnum of three months, it was announced, on the very eve of the inauguration of the regent, that the king was himself again, the nation was wild with delight. On the evening of the day on which His Majesty resumed his functions a spontaneous illumination, the most general that had ever been seen in England, brightened the whole vast space from Highgate to Tooting, and from Hammer-smith to Greenwich. On the day on which he returned thanks in the cathedral of his capital all the horses and carriages within a hundred miles of London were too few for the multitudes which flocked to see him pass through the streets. A second illumination followed, which was even superior to the first in magnificence. Pitt with difficulty escaped from the tumultuous kindness of an innumerable multitude which insisted on drawing his coach from St Paul's Churchyard to Downing Street. This was the moment at which his fame and fortune may be said to have reached the zenith. His influence in the closet was as great as that of Carr or Villiers had been. His dominion over the parliament was more absolute than that of Walpole or Pelham had been. He was at the same time as high in the favour of the populace as ever Wilkes or Sacheverell had been. Nothing did more to raise his character than his noble poverty. It was well known that, if he had been dismissed from office after more than five years of boundless power, he would hardly have carried out with him a sum sufficient to furnish the set of chambers in which, as he cheerfully declared, he meant to resume the practice of the law. His advisers, however, were by no means disposed to suffer him to depend on daily toil for his daily bread. The voluntary contributions which were awaiting his acceptance in the city of London alone would have sufficed to make him a rich man. But it may be doubted whether his haughty spirit would have stooped to accept a provision so honourably earned and so honourably bestowed.

To such a height of power and glory had this extraordinary man risen at twenty-nine years of age. And now the tide was on the turn. Only ten days after the triumphant procession to St Paul's, the states-general of France, after an interval of a hundred and seventy-four years, met at Versailles.

The nature of the great Revolution which followed was long very French imperfectly understood in this country. Burke saw much further Revolution than any of his contemporaries; but whatever his sagacity discerned was refracted and discoloured by his passions and his imagination. More than three years elapsed before the principles of the English administration underwent any material change. Nothing could as yet be milder or more strictly constitutional than the minister's domestic policy. Not a single act indicating an arbitrary temper or a jealousy of the people could be imputed to him. He had never applied to parliament for any extraordinary powers. He had never used with harshness the ordinary powers entrusted by the constitution to the executive Government. Not a single state prosecution which would even now be called oppressive had been instituted by him. Indeed, the only oppressive state prosecution instituted during the first eight years of his administration was that of Stockdale, which is to be attributed, not to the Government, but to the chiefs of the Opposition. In office, Pitt had redeemed the pledges which he had, at his entrance into public life, given to the supporters of parliamentary reform. He had, in 1783, brought forward a judicious plan for the improvement of the representative system, and had prevailed on the king, not only to refrain from talking against that plan, but to recommend it to the Houses in a speech from the throne.<sup>1</sup> This attempt failed; but there can be little doubt that, if the French Revolution had not produced a violent reaction of public feeling, Pitt would have performed, with little difficulty and no danger, that great work which, at a later period, Lord Grey could accomplish only by means which for a time loosened the very foundations of the commonwealth. When the atrocities of the slave trade were first brought under the consideration of parliament, no abolitionist was more zealous than Pitt. When sickness prevented Wilberforce from appearing in public, his place was most efficiently supplied by his friend the minister. A humane bill, which mitigated the horrors of the middle passage, was, in 1783, carried by the eloquence and determined spirit of Pitt, in spite of the opposition of some of his own colleagues; and it ought always to be remembered to his honour that, in order to carry that bill, he kept the Houses sitting, in spite of many murmurs, long after the business of the Government had been done

<sup>1</sup> The speech with which the king opened the session of 1783 concluded with an assurance that His Majesty would heartily concur in every measure which could tend to secure the true principles of the constitution. These words were at the time understood to refer to Pitt's Reform Bill.

and the Appropriation Act passed. In 1791 he cordially concurred with Fox in maintaining the sound constitutional doctrine that an impeachment is not terminated by a dissolution. In the course of the same year the two great rivals contended side by side in a far more important cause. They are fairly entitled to divide the high honour of having added to our statute-book the inestimable law which places the liberty of the press under the protection of juries. On one occasion, and one alone, Pitt, during the first half of his long administration, acted in a manner unworthy of an enlightened Whig. In the debate on the Test Act, he stooped to gratify the master whom he served, the university which he represented, and the great body of clergymen and country gentlemen on whose support he rested, by talking, with little heartiness indeed, and with no asperity, the language of a Tory. With this single exception, his conduct from the end of 1783 to the middle of 1792 was that of an honest friend of civil and religious liberty.

Nor did anything, during that period, indicate that he loved war, or harboured any malevolent feeling against any neighbouring nation. Those French writers who have represented him as a Hannibal sworn in childhood by his father to bear eternal hatred to France, as having, by mysterious intrigues and lavish bribes, instigated the leading Jacobins to commit those excesses which dishonoured the Revolution, as having been the real author of the first coalition, know nothing of his character or of his history. So far was he from being a deadly enemy to France that his laudable attempts to bring about a closer connexion with that country by means of a wise and liberal treaty of commerce brought on him the severe censure of the Opposition. He was told in the House of Commons that he was a degenerate son, and that his partiality for the hereditary foes of our island was enough to make his great father's bones stir under the pavement of the Abbey.

Its influence in English politics.

And this man, whose name, if he had been so fortunate as to die in 1792, would now have been associated with peace, with freedom, with philanthropy, with temperate reform, with mild and constitutional administration, lived to associate his name with arbitrary government, with harsh laws harshly executed, with alien bills, with gagging bills, with suspensions of the Habeas Corpus Act, with cruel punishments inflicted on some political agitators, with unjustifiable prosecutions instituted against others, and with the most costly and most sanguinary wars of modern times. He lived to be held up to obloquy as the stern oppressor of England, and the indefatigable disturber of Europe. Poets, contrasting his earlier with his later years, likened him sometimes to the apostle who kissed in order to betray, and sometimes to the evil angels who kept not their first estate. A satirist of great genius introduced the fiends of famine, slaughter, and fire, proclaiming that they had received their commission from one whose name was formed of four letters, and promising to give their employer ample proofs of gratitude. Famine would gnaw the multitude till they should rise up against him in madness. The demon of slaughter would impel them to tear him from limb to limb. But fire boasted that she alone could reward him as he deserved, and that she would eling round him to all eternity. By the French press and the French tribune every crime that disgraced and every calamity that afflicted France was ascribed to the monster Pitt and his guineas. While the Jacobins were dominant it was he who had corrupted the Gironde, who had raised Lyons and Bordeaux against the Convention, who had suborned Paris to assassinate Lepelletier, and Cecilia Regnault to assassinate Robespierre. When the Thermidorian reaction came, all the atrocities of the Reign of Terror were imputed to him. Collot D'Herbois and Fouquier Tinville had been his pensioners. It was he who had hired the murderers of September, who had dictated the pamphlets of Marat and the carnages of Barère, who had paid Lebon to deluge Arras with blood and Carrier to choke the Loire with corpses.

The truth is that he liked neither war nor arbitrary government. He was a lover of peace and freedom, driven, by a stress against which it was hardly possible for any will or any intellect to struggle, out of the course to which his inclinations pointed, and for which his abilities and acquirements fitted him, and forced into a policy repugnant to his feelings and unsuited to his talents.

The charge of apostasy is grossly unjust. A man ought no more to be called an apostate because his opinions alter with the opinions of the great body of his contemporaries than he ought to be called an Oriental traveller because he is always going round from west to east with the globe and everything that is upon it. Between the spring of 1789 and the close of 1792 the public mind of England underwent a great change. If the change of Pitt's sentiments attracted peculiar notice, it was not because he changed more than his neighbours, for in fact he changed less than most of them, but because his position was far more conspicuous than theirs, because he was, till Bonaparte appeared, the individual who filled the greatest space in the eyes of the inhabitants of the civilized world. During a short time the nation, and Pitt as one of the nation, looked with interest and approbation on the French Revolution. But soon vast confiscations, the violent sweeping away of ancient institutions, the domination of clubs, the barbarities of mobs

maddened by fanaticism and hatred, produced a reaction here. The court, the nobility, the gentry, the clergy, the manufacturers, the merchants, in short nineteen-twentieths of those who had good roofs over their heads and good coats on their backs, became eager intolerant Antijacobins. This feeling was at least as strong among the minister's adversaries as among his supporters. Fox in vain attempted to restrain his followers. All his genius, all his vast personal influence, could not prevent them from rising up against him in general mutiny. Burke set the example of revolt; and Burke was in no long time joined by Portland, Spencer, Fitzwilliam, Loughborough, Carlisle, Malmesbury, Windham, Elliot. In the House of Commons the followers of the great Whig statesman and orator diminished from about a hundred and sixty to fifty. In the House of Lords he had but ten or twelve adherents left. There can be no doubt that there would have been a similar mutiny on the ministerial benches, if Pitt had obstinately resisted the general wish. Pressed at once by his master and by his colleagues, by old friends and by old opponents, he abandoned, slowly and reluctantly, the policy which was dear to his heart. He laboured hard to avert the European war. When the European war broke out, he still flattered himself that it would not be necessary for this country to take either side. In the spring of 1792 he congratulated the parliament on the prospect of long and profound peace, and proved his sincerity by proposing large remissions of taxation. Down to the end of that year he continued to cherish the hope that England might be able to preserve neutrality. But the passions which raged on both sides of the Channel were not to be restrained. The republicans who ruled France were inflamed by a fanaticism resembling that of the Mussulmans, who, with the Koran in one hand and the sword in the other, went forth conquering and converting, eastward to the Bay of Bengal, and westward to the Pillars of Hercules. The higher and middle classes of England were animated by zeal not less fiery than that of the crusaders who raised the cry of *Deus vult* at Clermont. The impulse which drove the two nations to a collision was not to be arrested by the abilities or by the authority of any single man. As Pitt was in front of his fellows, and towered high above them, he seemed to lead them. But in fact he was violently pushed on by them, and, had he held back but a little more than he did, would have been thrust out of their way or trampled under their feet.

He yielded to the current; and from that day his misfortunes began. The truth is that there were only two consistent courses period before him. Since he did not choose to oppose himself, side by side with Fox, to the public feeling, he should have taken the advice of Burke, and should have availed himself of that feeling to the full extent. If it was impossible to preserve peace, he should have adopted the only policy which could lead to victory. He 1792-1801. should have proclaimed a holy war for religion, morality, property, order, public law, and should have thus opposed to the Jacobins an energy equal to their own. Unhappily he tried to find a middle path; and he found one which united all that was worst in both extremes. He went to war; but he would not understand the War peculiar character of that war. He was obstinately blind to the plain fact that he was contending against a state which was also a sect, and that the new quarrel between England and France was of quite a different kind from the old quarrels about colonies in America and fortresses in the Netherlands. He had to combat frantic enthusiasm, boundless ambition, restless activity, the wildest and most audacious spirit of innovation; and he acted as if he had had to deal with the barbers and fops of the old court of Versailles, with Madame de Pompadour and the Abbé de Benis. It was pitiable to hear him, year after year, proving to an admiring audience that the wicked republic was exhausted, that she could not hold out, that her credit was gone, that her assignats were not worth more than the paper of which they were made,—as if credit was necessary to a government of which the principle was rapine, as if Alboin could not turn Italy into a desert till he had negotiated a loan at five per cent., as if the exchequer bills of Attila had been at par. It was impossible that a man who so completely mistook the nature of a contest could carry on that contest successfully. Great as Pitt's abilities were, his military administration was that of a driveller. He was at the head of a nation Military engaged in a struggle for life and death, of a nation eminently distinguished by all the physical and all the moral qualities which make excellent soldiers. The resources at his command were unlimited. The parliament was even more ready to grant him men and money than he was to ask for them. In such an emergency, and with such means, such a statesman as Richelieu, as Louvois, as Chatham, as Wellesley, would have created in a few months one of the finest armies in the world, and would soon have discovered and brought forward generals worthy to command such an army. Germany might have been saved by another Blenheim; Flanders recovered by another Ramillies; another Poitiers might have delivered the Royalist and Catholic provinces of France from a yoke which they abhorred, and might have spread terror even to the barriers of Paris. But the fact is that, after eight years of war, after a vast destruction of life, after an expenditure of wealth

far exceeding the expenditure of the American War, of the Seven Years' War, of the War of the Austrian Succession, and of the War of the Spanish Succession united, the English army under Pitt was the laughing-stock of all Europe. It could not boast of one single brilliant exploit. It had never shown itself on the Continent but to be beaten, chased, forced to re-embark, or forced to capitulate. To take some sugar island in the West Indies, to scatter some mob of half-naked Irish peasants—such were the most splendid victories won by the British troops under Pitt's auspices.

Naval  
adminis-  
tration.

The English navy no mismanagement could ruin. But during a long period whatever mismanagement could do was done. The earl of Chatham, without a single qualification for high public trust, was made, by fraternal partiality, first lord of the admiralty, and was kept in that great post during two years of a war in which the very existence of the state depended on the efficiency of the fleet. He continued to doze away and trifle away the time which ought to have been devoted to the public service, till the whole mercantile body, though generally disposed to support the Government, complained bitterly that our flag gave no protection to our trade. Fortunately he was succeeded by George, Earl Spencer, one of those chiefs of the Whig party who, in the great schism caused by the French Revolution, had followed Burke. Lord Spencer, though inferior to many of his colleagues as an orator, was decidedly the best administrator among them. To him it was owing that a long and gloomy succession of days of fasting, and most emphatically of humiliation, was interrupted, twice in the short space of eleven months, by days of thanksgiving for great victories.

It may seem paradoxical to say that the incapacity which Pitt showed in all that related to the conduct of the war is, in some sense, the most decisive proof that he was a man of very extraordinary abilities. Yet this is the simple truth. For assuredly one-tenth part of his errors and disasters would have been fatal to the power and influence of any minister who had not possessed, in the highest degree, the talents of a parliamentary leader. While his schemes were confounded, while his predictions were falsified, while the coalitions which he had laboured to form were falling to pieces, while the expeditions which he had sent forth at enormous cost were ending in rout and disgrace, while the enemy against whom he was feebly contending was subjugating Flanders and Brabant, the electorate of Mainz and the electorate of Treves, Holland, Piedmont, Liguria, Lombardy, his authority over the House of Commons was constantly becoming more and more absolute. There was his empire. There were his victories—his Lodi and his Arcola, his Rivoli and his Marengo. If some great misfortune, a pitched battle lost by the allies, the annexation of a new department to the French republic, a sanguinary insurrection in Ireland, a mutiny in the fleet, a panic in the city, a run on the bank, had spread dismay through the ranks of his majority, that dismay lasted only till he rose from the treasury bench, drew up his haughty head, stretched his arm with commanding gesture, and poured forth, in deep and sonorous tones, the lofty language of inextinguishable hope and inflexible resolution. Thus, through a long and calamitous period, every disaster that happened without the walls of parliament was regularly followed by a triumph within them. At length he had no longer an Opposition to encounter. Of the great party which had contended against him during the first eight years of his administration more than one-half now marched under his standard, with his old competitor the duke of Portland at their head; and the rest had, after many vain struggles, quitted the field in despair. Fox had retired to the shades of St Anne's Hill, and had there found, in the society of friends whom no vicissitude could estrange from him, of a woman whom he tenderly loved, and of the illustrious dead of Athens, of Rome, and of Florence, ample compensation for all the misfortunes of his public life. Session followed session with scarcely a single division. In the eventful year 1799 the largest minority that could be mustered against the Government was twenty-five.

Domestic  
policy.

In Pitt's domestic policy there was at this time assuredly no want of vigour. While he offered to French Jacobinism a resistance so feeble that it only encouraged the evil which he wished to suppress, he put down English Jacobinism with a strong hand. The Habeas Corpus Act was repeatedly suspended. Public meetings were placed under severe restraints. The Government obtained from parliament power to send out of the country aliens who were suspected of evil designs; and that power was not suffered to be idle. Writers who propounded doctrines adverse to monarchy and aristocracy were proscribed and punished without mercy. It was hardly safe for a republican to avow his political creed over his breakfast and his bottle of port at a chop-house. The old laws of Scotland against sedition, laws which were considered by Englishmen as barbarous, and which a succession of Governments had suffered to rust, were now furnished up and sharpened anew. Men of cultivated minds and polished manners were, for offences which at Westminster would have been treated as mere misdemeanours, sent to herd with felons at Botany Bay. Some reformers, whose opinions were extravagant, and whose language was intemperate, but who had never dreamed of subverting the

government by physical force, were indicted for high treason, and were saved from the gallows only by the righteous verdicts of juries. This severity was at the time loudly applauded by alarmists whom fear had made cruel, but will be seen in a very different light by posterity. The truth is that the Englishmen who wished for a revolution were, even in number, not formidable, and in everything but number a faction utterly contemptible, without arms, or funds, or plans, or organization, or leader. There can be no doubt that Pitt, strong as he was in the support of the great body of the nation, might easily have repressed the turbulence of the discontented minority by firmly yet temperately enforcing the ordinary law. Whatever vigour he showed during this unfortunate part of his life was vigour out of place and season. He was all feebleness and languor in his conflict with the foreign enemy who was really to be dreaded, and reserved all his energy and resolution for the domestic enemy who might safely have been despised.

One part only of Pitt's conduct during the last eight years of Irish the 18th century deserves high praise. He was the first English policy minister who formed great designs for the benefit of Ireland. The manner in which the Roman Catholic population of that unfortunate country had been kept down during many generations seemed to him unjust and cruel; and it was scarcely possible for a man of his abilities not to perceive that, in a contest against the Jacobins, the Roman Catholics were his natural allies. Had he been able to do all that he wished, it is probable that a wise and liberal policy would have averted the rebellion of 1798. But the difficulties which he encountered were great, perhaps insurmountable; and the Roman Catholics were, rather by his misfortune than by his fault, thrown into the hands of Jacobins. There was a third great rising of the Irishry against the Englishry, a rising not less formidable than the risings of 1641 and 1689. The Englishry remained victorious; and it was necessary for Pitt, as it had been necessary for Oliver Cromwell and William of Orange before him, to consider how the victory should be used. It is only just to his memory to say that he formed a scheme of policy so grand and so simple, so righteous and so humane, that it would alone entitle him to a high place among statesmen. He determined to make Ireland one kingdom with England, and, at the same time, to relieve the Roman Catholic laity from civil disabilities, and to grant a public maintenance to the Roman Catholic clergy. Had he been able to carry these noble designs into effect, the Union would have been a union indeed. It would have been inseparably associated in the minds of the great majority of Irishmen with civil and religious freedom; and the old parliament in College Green would have been regretted only by a small knot of discarded jobbers and oppressors, and would have been remembered by the body of the nation with the loathing and contempt due to the most tyrannical and the most corrupt assembly that had ever sat in Europe. But Pitt could execute only one half of what he had projected. He succeeded in obtaining the consent of the parliaments of both kingdoms to the Union; but that reconciliation of races and sects without which the Union could exist only in name was not accomplished. He was well aware that he was likely to find difficulties in the closet. But he flattered himself that, by cautious and dexterous management, those difficulties might be overcome. Unhappily, there were traitors and sycophants in high place who did not suffer him to take his own time and his own way, but prematurely disclosed his scheme to the king, and disclosed it in the manner most likely to irritate and alarm a weak and diseased mind. His Majesty absurdly imagined that his coronation oath bound him to refuse his assent to any bill for relieving Roman Catholics from civil disabilities. To argue with him was impossible. Dundas tried to explain the matter, but was told to keep his Scotch metaphysics to himself. Pitt and Pitt's ablest colleagues resigned their offices. It was necessary that the king should make a new arrangement. But by this time his anger and distress had brought back the malady which had, many years before, incapacitated him for the discharge of his functions. He actually assembled his family, read the coronation oath to them, and told them that, if he broke it, the crown would immediately pass to the house of Savoy. It was not until after an interregnum of several weeks that he regained the full use of his small faculties, and that a ministry after his own heart was at length formed.

The materials out of which he had to construct a Government were neither solid nor splendid. To that party, weak in numbers, but strong in every kind of talent, which was hostile to the domestic and foreign policy of his late advisers, he could not have recourse. For that party, while it differed from his late advisers on every point on which they had been honoured with his approbation, cordially agreed with them as to the single matter which had brought on them his displeasure. All that was left to him was to call up the rear ranks of the front rank of the of parliamentary talents, a cabinet was formed containing hardly a single man who in parliamentary talents could be considered as even of the second rate. The most important offices in the state were bestowed on decorous and laborious mediocrity. Henry Addington was at the

Adding- head of the treasury. He had been an early, indeed a hereditary, friend of Pitt, and had by Pitt's influence been placed, while still a young man, in the chair of the House of Commons. He was universally admitted to have been the best Speaker that had sat in that chair since the retirement of Onslow. But nature had not bestowed on him very vigorous faculties; and the highly respectable situation which he long occupied with honour had rather unfitted than fitted him for the discharge of his new duties. His business had been to bear himself evenly between contending factions. He had taken no part in the war of words; and he had always been addressed with marked deference by the great orators who thundered against each other from his right and from his left. It was not strange that when, for the first time, he had to encounter keen and vigorous antagonists, who dealt hard blows without the smallest ceremony, he should have been awkward and unready, or that the air of dignity and authority which he had acquired in his former post, and of which he had not divested himself, should have made his helplessness laughable and pitiable. Nevertheless, during many months, his power seemed to stand firm. He was a favourite with the king, whom he resembled in narrowness of mind, and to whom he was more obsequious than Pitt had ever been. The nation was put into high good humour by a peace with France. The enthusiasm with which the upper and middle classes had rushed into the war had spent itself. Jacobinism was no longer formidable. Everywhere there was a strong reaction against what was called the atheistical and anarchical philosophy of the 18th century. Bonaparte, new first consul, was busied in constructing out of the ruins of old institutions a new ecclesiastical establishment and a new order of knighthood. That nothing less than the dominion of the whole civilized world would satisfy his selfish ambition was not yet suspected; nor did even wise men see any reason to doubt that he might be as safe a neighbour as any prince of the house of Bourbon had been. The treaty of Amiens was therefore hailed by the great body of the English people with extravagant joy. The popularity of the minister was for the moment immense. His want of parliamentary ability was, as yet, of little consequence; for he had scarcely any adversary to encounter. The old Opposition, delighted by the peace, regarded him with favour. A new Opposition had indeed been formed by some of the late ministers, and was led by Grenville in the House of Lords and by Windham in the House of Commons. But the new Opposition could scarcely muster ten votes, and was regarded with no favour by the country. On Pitt the ministers relied as on their firmest support. He had not, like some of his colleagues, retired in anger. He had expressed the greatest respect for the conscientious scruple which had taken possession of the royal mind; and he had promised his successors all the help in his power. In private his advice was at their service. In parliament he took his seat on the bench behind them, and in more than one debate defended them with powers far superior to their own. The king perfectly understood the value of such assistance. On one occasion, at the palace, he took the old minister and the new minister aside. "If we three," he said, "keep together, all will go well."

Relations  
between  
Pitt and  
Addington.

But it was hardly possible, human nature being what it is, and more especially Pitt and Addington being what they were, that this union should be durable. Pitt, conscious of superior powers, imagined that the place which he had quitted was now occupied by a mere puppet which he had set up, which he was to govern while he suffered it to remain, and which he was to sling aside as soon as he wished to resume his old position. Nor was it long before he began to pine for the power which he had relinquished. He had been so early raised to supreme authority in the state, and had enjoyed that authority so long, that it had become necessary to him. In retirement his days passed heavily. He could not, like Fox, forget the pleasures and cares of ambition in the company of Euripides or Herodotus. Pride restrained him from intimating, even to his dearest friends, that he wished to be again minister. But he thought it strange, almost ungrateful, that his wish had not been divined, that it had not been anticipated by one whom he regarded as his deputy.

Addington, on the other hand, was by no means inclined to descend from his high position. He was, indeed, under a delusion much resembling that of Abu Hassan in the Arabian tale. His brain was turned by his short and unreal caliphate. He took his elevation quite seriously, attributed it to his own merit, and considered himself as one of the great triumvirate of English statesmen, as worthy to make a third with Pitt and Fox.

Such being the feelings of the late minister and of the present minister, a rupture was inevitable; and there was no want of persons bent on making that rupture speedy and violent. Some of these persons wounded Addington's pride by representing him as a lackey, sent to keep a place on the treasury bench till his master should find it convenient to come. Others took every opportunity of praising him at Pitt's expense. Pitt had waged a long, a bloody, a costly, an unsuccessful war. Addington had made peace. Pitt had suspended the constitutional liberties of Englishmen. Under Addington those liberties were again enjoyed. Pitt had wasted

the public resources. Addington was . . . them. It was sometimes but too evident that . . . were not unpleasing to Addington. Pitt became cold and reserved. During many months he remained at a distance from London. Meanwhile his most intimate friends, in spite of his declarations that he made no complaint, and that he had no wish for office, exerted themselves to effect a change of ministry. His favourite disciple, George Canning, young, ardent, ambitious, with great powers and great virtues, but with a temper too restless and a wit too satirical for his own happiness, was indefatigable. He spoke; he wrote; he intrigued; he tried to induce a large number of the supporters of the Government to sign a round robin desiring a change; he made game of Addington and of Addington's relations in a succession of lively pasquinades. The minister's partisans retorted with equal acrimony, if not with equal vivacity. Pitt could keep out of the affray only by keeping out of politics altogether; and this it soon became impossible for him to do. Had Napoleon, content with the first place among the sovereigns of the Continent, and with a military reputation surpassing that of Marlborough or of Turenne, devoted himself to the noble task of making France happy by mild administration and wise legislation, our country might have long continued to tolerate a Government of fair intentions and feeble abilities. Unhappily, the treaty of Amiens had scarcely been signed when the restless ambition and the insupportable insolence of the first consul convinced the great body of the English people that the peace so eagerly welcomed was only a precarious armistice. As it became clearer and clearer that a war for the dignity, the independence, the very existence of the nation was at hand, men looked with increasing uneasiness on the weak and languid cabinet which would have to contend against an enemy who united more than the power of Louis the Great to more than the genius of Frederick the Great. It is true that Addington might easily have made a better war minister than Pitt, and could not possibly have been a worse. But Pitt had cast a spell on the public mind. The eloquence, the judgment, the calm and disdainful firmness which he had during many years displayed in parliament deluded the world into the belief that he must be eminently qualified to superintend every department of politics; and they imagined, even after the miserable failures of Dunkirk, of Quiberon, and of the Helder, that he was the only statesman who could cope with Bonaparte. This feeling was nowhere stronger than among Addington's own colleagues. The pressure put on him was so strong that he could not help yielding to it; yet, even in yielding, he showed how far he was from knowing his own place. His first proposition was that Pitt declines nominal head of the administration, and that the real power should be divided between Pitt and himself, who were to be secretaries of state. Pitt, as might have been expected, refused even to discuss such a scheme, and talked of it with bitter mirth. "Which secretarship was offered to you?" his friend Wilberforce asked. "Really," said Pitt, "I had not the curiosity to inquire." Addington was frightened into bidding higher. He offered to resign the treasury to Pitt, on condition that there should be no extensive change in the Government. But Pitt would listen to no such terms. Then came a dispute such as often arises after negotiations orally conducted, even when the negotiators are men of strict honour. Pitt gave one account of what had passed; Addington gave another; and, though the discrepancies were not such as necessarily implied any intentional violation of truth on either side, both were greatly exasperated.

Meanwhile the quarrel with the first consul had come to a crisis. On the 16th of May 1803 the king sent a message calling on the House of Commons to support him in withstanding the ambitious and encroaching policy of France; and on the 22d the House took the message into consideration.

Pitt had now been living many months in retirement. There had been a general election since he had spoken in parliament, and there were two hundred members who had never heard him. It was known that on this occasion he would be in his place, and curiosity was wound up to the highest point. Unfortunately, the shorthand writers were, in consequence of some mistake, shut out on that day from the gallery, so that the newspapers contained only a very meagre report of the proceedings. But several accounts of what passed are extant; and of those accounts the most interesting is contained in an unpublished letter written by a very young member, John William Ward, afterwards earl of Dudley. When Pitt rose, he was received with loud cheering. At every pause in his speech there was a burst of applause. The peroration is said to have been one of the most animated and magnificent ever heard in parliament. "Pitt's speech," Fox wrote a few days later, "was admired very much, and very justly. I think it was the best he ever made in that style." The debate was adjourned; and on the second night Fox replied to it in an oration which, as the most zealous Pittites were forced to acknowledge, left the palm of eloquence doubtful. Addington made a pitiable appearance between the two great rivals; and it was observed that Pitt, while exhorting the Commons to stand resolutely by the executive Government

against France, said not a word indicating esteem or friendship for the prime minister.

War was speedily declared. The first consul threatened to invade England at the head of the conquerors of Belgium and Italy, and formed a great camp near the Straits of Dover. On the other side of those straits the whole population of our island was ready to rise up as one man in defence of the soil. At this conjuncture, as at some other great conjunctures in our history—the conjuncture of 1660, for example, and the conjuncture of 1688—there was a general disposition among honest and patriotic men to forget old quarrels, and to regard as a friend every person who was ready, in the existing emergency, to do his part towards the saving of the state. A coalition of all the first men in the country would, at that moment, have been as popular as the coalition of 1783 had been unpopular. Alone in the kingdom the king looked with perfect complacency on a cabinet in which no man superior to himself in genius was to be found, and was so far from being willing to admit all his ablest subjects to office that he was bent on excluding them all.

A few months passed before the different parties which agreed in regarding the Government with dislike and contempt came to an understanding with each other. But in the spring of 1804 it became evident that the weakest of ministries would have to defend itself against the strongest of Oppositions, an Opposition made up of three Oppositions, each of which would, separately, have been formidable from ability, and which, when united, were also formidable from number. The party which had opposed the peace, headed by Grenville and Windham, and the party which had opposed the renewal of the war, headed by Fox, concurred in thinking that the men now in power were incapable of either making a good peace or waging a vigorous war. Pitt had in 1802 spoken for peace against the party of Grenville, and had in 1803 spoken for war against the party of Fox. But of the capacity of the cabinet, and especially of its chief, for the conduct of great affairs, he thought as meanly as either Fox or Grenville. Questions were easily found on which all the enemies of the Government could act cordially together. The unfortunate first lord of the treasury, who had, during the earlier months of his administration, been supported by Pitt on one side and by Fox on the other, now had to answer Pitt and to be answered by Fox. Two sharp debates, followed by close divisions, made him weary of his post. It was known, too, that the Upper House was ever more hostile to him than the Lower, that the Scotch representative peers wavered, that there were signs of mutiny among the bishops. In the cabinet itself there was discord, and, worse than discord, treachery. It was necessary to give way; the ministry was dissolved, and the task of forming a Government was entrusted to Pitt.

Adding-  
ton  
ministry  
resigns.

Pitt was of opinion that there was now an opportunity, such as had never before offered itself, and such as might never offer itself again, of uniting in the public service, on honourable terms, all the eminent talents of the kingdom. The passions to which the French Revolution had given birth were extinct. The madness of the innovator and the madness of the alarmist had alike had their day. Jacobinism and Antijacobinism had gone out of fashion together. The most liberal statesman did not think that season propitious for schemes of parliamentary reform; and the most conservative statesman could not pretend that there was any occasion for gagging bills and suspensions of the Habeas Corpus Act. The great struggle for independence and national honour occupied all minds; and those who were agreed as to the duty of maintaining that struggle with vigour might well postpone to a more convenient time all disputes about matters comparatively unimportant. Strongly impressed by these considerations, Pitt wished to form a ministry including all the first men in the country. The treasury he reserved for himself; and to Fox he proposed to assign a share of power little inferior to his own.

The plan was excellent; but the king would not hear of it. Dull, obstinate, unforgiving, and at that time half mad, he positively refused to admit Fox into his service. Anybody else, even men who had gone as far as Fox, or further than Fox, in what His Majesty considered as Jacobinism—Sheridan, Grey, Erskine—should be graciously received, but Fox never. During several hours Pitt laboured in vain to reason down this senseless antipathy. That he was perfectly sincere there can be no doubt; but it was not enough to be sincere—he should have been resolute. Had he declared himself determined not to take office without Fox, the royal obstinacy would have given way, as it gave way, a few months later, when opposed to the immutable resolution of Lord Grenville. In an evil hour Pitt yielded. He flattered himself with the hope that, though he consented to forego the aid of his illustrious rival, there would still remain ample materials for the formation of an efficient ministry. That hope was cruelly disappointed. Fox entreated his friends to leave personal considerations out of the question, and declared that he would support, with the utmost cordiality, an efficient and patriotic ministry from which he should be himself excluded. Not only his friends, however, but Grenville and Grenville's adherents answered with one voice that the question was not personal, that a great constitu-

tional principle was at stake, and that they would not take office while a man eminently qualified to render service to the commonwealth was placed under a ban merely because he was disliked at court. All that was left to Pitt was to construct a Government out of the wreck of Addington's feeble administration. The small circle of his personal retainers furnished him with a very few useful assistants, particularly Dundas (who had been created Viscount Melville), Lord Harrowby, and Canning.

Such was the inauspicious manner in which Pitt entered on his second administration. The whole history of that administration Pitt was of a piece with the commencement. Almost every month administration brought some new disaster or disgrace. To the war with France there was soon added a war with Spain. The opponents of the ministry May 12 were numerous, able, and active. His most useful coadjutors he soon lost. Sickness deprived him of the help of Lord Harrowby. It was discovered that Lord Melville had been guilty of highly culpable laxity in transactions relating to public money. He was censured by the House of Commons, driven from office, ejected from the Privy Council, and impeached of high crimes and misdemeanours. The blow fell heavy on Pitt. It gave him, he said in parliament, a deep pang; and, as he uttered the word pang his lip quivered, his voice shook, he paused, and his hearers thought that he was about to burst into tears. Such tears shed by Eldon would have moved nothing but laughter. Shed by the warm-hearted and open-hearted Fox, they would have moved sympathy, but would have caused no surprise. But a tear from Pitt would have been something portentous. He suppressed his emotion, however, and proceeded with his usual majestic self-possession.

His difficulties compelled him to resort to various expedients. At one time Addington was persuaded to accept office with a peerage; but he brought no additional strength to the Government. Though he went through the form of reconciliation, it was impossible for him to forget the past. While he remained in place he was jealous and punctilious; and he soon retired again. At another time Pitt renewed his efforts to overcome his master's aversion to Fox; and it was rumoured that the king's obstinacy was gradually giving way. But, meanwhile, it was impossible for the minister to conceal from the public eye the decay of his health and the constant anxiety which gnawed at his heart. His sleep was broken. His food ceased to nourish him. All who passed him in the park, all who had interviews with him in Downing Street, saw misery written in his face. The peculiar look which he wore during the last months of his life was often pathetically described by Wilberforce, who used to call it the Austerlitz look.

Still the vigour of Pitt's intellectual faculties and the intrepid haughtiness of his spirit remained unaltered. He had staked everything on a great venture. He had succeeded in forming another mighty coalition against the French ascendancy. The united forces of Austria, Russia, and England might, he hoped, oppose an insurmountable barrier to the ambition of the common enemy. But the genius and energy of Napoleon prevailed. While the English troops were preparing to embark for Germany, while the Russian troops were slowly coming up from Poland, he, with rapidity unprecedented in modern war, moved a hundred thousand men from the shores of the ocean to the Black Forest, and compelled a great Austrian army to surrender at Ulm. To the first faint rumours of this calamity Pitt would give no credit. He was irritated by the alarms of those around him. "Do not believe a word of it," he said; "it is all a fiction." The next day he received a Dutch newspaper containing the capitulation. He knew no Dutch. It was Sunday, and the public offices were shut. He carried the paper to Lord Malmesbury, who had been minister in Holland; and Lord Malmesbury translated it. Pitt tried to bear up, but the shock was too great; and he went away with death in his face.

The news of the battle of Trafalgar arrived four days later, and seemed for a moment to revive him. Forty-eight hours after that most glorious and most mournful of victories had been announced to the country came the Lord Mayor's Day; and Pitt dined at Guildhall. His popularity had declined. But on this occasion the multitude, greatly excited by the recent tidings, welcomed him enthusiastically, took off his horses in Cheapside, and drew his carriage up King Street. When his health was drunk, he returned thanks in two or three of those stately sentences of which he had a boundless command. Several of those who heard him laid up his words in their hearts; for they were the last words that he ever uttered in public: "Let us hope that England, having saved herself by her energy, may save Europe by her example."

This was but a momentary rally. Austerlitz soon completed what Ulm had begun. Early in December Pitt had retired to Bath, in the hope that he might there gather strength for the approaching session. While he was languishing there on his sofa arrived the news that a decisive battle had been fought and lost in Moravia, that the coalition was dissolved, that the Continent was at the feet of France. He sank down under the blow. Ten days later he was so emaciated that his most intimate friends hardly knew him. He came up from Bath by slow journeys, and on the 11th of January 1806 reached his villa at Putney. Parlia-

ment was to meet on the 21st. On the 20th was to be the parliamentary dinner at the house of the first lord of the treasury in Downing Street; and the cards were already issued. But the days of the great minister were numbered. The only chance for his life, and that a very slight chance, was that he should resign his office, and pass some months in profound repose. His colleagues paid him very short visits, and carefully avoided political conversation. But his spirit, long accustomed to dominion, could not, even in that extremity, relinquish hopes which everybody but himself perceived to be vain. On the day on which he was carried into his bedroom at Putney the Marquis Wellesley, whom he had long loved, whom he had sent to govern India, and whose administration had been eminently able, energetic, and successful, arrived in London after an absence of eight years. The friends saw each other once more. There was an affectionate meeting and a last parting. That it was a last parting Pitt did not seem to be aware. He fancied himself to be recovering, talked on various subjects cheerfully and with an unclouded mind, and pronounced a warm and discerning eulogium on the marquis's brother Arthur. "I never," he said, "met with any military man with whom it was so satisfactory to converse." The excitement and exertion of this interview were too much for the sick man. He fainted away; and Lord Wellesley left the house convinced that the close was fast approaching.

And now members of parliament were fast coming up to London. The chiefs of the Opposition met for the purpose of considering the course to be taken on the first day of the session. It was easy to guess what would be the language of the king's speech, and of the address which would be moved in answer to that speech. An amendment condemning the policy of the Government had been prepared, and was to have been proposed in the House of Commons by Lord Henry Petty, a young nobleman who had already won for himself that place in the esteem of his country which, after the lapse of more than half a century, he still retains.<sup>1</sup> He was unwilling, however, to come forward as the accuser of one who was incapable of defending himself. Lord Grenville, who had been informed of Pitt's state by Lord Wellesley, and had been deeply affected by it, earnestly recommended forbearance; and Fox, with characteristic generosity and good nature, gave his voice against attacking his now helpless rival. "Sunt lacrymæ rerum," he said, "et mentem mortalia tangunt." On the first day, therefore, there was no debate. It was rumoured that evening that Pitt was better. But on the following morning his physicians pronounced that there were no hopes. The commanding faculties of which he had been too proud were beginning to fail. His old tutor and friend, the bishop of Lincoln, informed him of his danger, and gave such religious advice and consolation as a confused and obscured mind could receive. Stories were told of devout sentiments fervently uttered by the dying man. But these stories found no credit with anybody who knew him. Wilberforce pronounced it impossible that they could be true; "Pitt," he added, "was a man who always said less than he thought on such topics." It was asserted in many after-dinner speeches, Grub Street elegies, and academic prize poems and prize declamations that the great minister died exclaiming, "Oh my country!" This is a fable, but it is true that the last words which he uttered, while he knew what he said, were broken exclamations about the alarming state of public affairs. He ceased to breathe on the morning of the 23rd of January 1806, the twenty-fifth anniversary of the day on which he first took his seat in parliament. He was in his forty-seventh year, and had been during near nineteen years first lord of the treasury, and undisputed chief of the administration. Since parliamentary government was established in England, no English statesman has held supreme power so long. Walpole, it is true, was first lord of the treasury during more than twenty years, but it was not till Walpole had been some time first lord of the treasury that he could be properly called prime minister.

It was moved in the House of Commons that Pitt should be honoured with a public funeral and a monument. The motion was opposed by Fox in a speech which deserves to be studied as a model of good taste and good feeling. The task was the most invidious that ever an orator undertook; but it was performed with a humanity and delicacy which were warmly acknowledged by the mourning friends of him who was gone. The motion was carried by 238 votes to 89.

The 22d of February was fixed for the funeral. The corpse having lain in state during two days in the Painted Chamber, was borne with great pomp to the northern transept of the Abbey. A splendid train of princes, nobles, bishops, and privy councillors followed. The grave of Pitt had been made near to the spot where his great father lay, near also to the spot where his great rival was soon to lie. The sadness of the assistants was beyond that of ordinary mourners. For he whom they were committing to the

dust had died of sorrows and anxieties of which none of the survivors could be altogether without a share. Wilberforce, who carried the banner before the hearse, described the awful ceremony with deep feeling. As the coffin descended into the earth, he said, the eagle face of Chatham from above seemed to look down with consternation into the dark house which was receiving all that remained of so much power and glory.

All parties in the House of Commons readily concurred in voting forty thousand pounds to satisfy the demands of Pitt's creditors. Some of his admirers seemed to consider the magnitude of his embarrassments as a circumstance highly honourable to him; but men of sense will probably be of a different opinion. It is far better, no doubt, that a great minister should carry his contempt of money to excess than that he should contaminate his hands with unlawful gain. But it is neither right nor becoming in a man to whom the public has given an income more than sufficient for his comfort and dignity to bequeath to that public a great debt, the effect of mere negligence and profusion. As first lord of the treasury and chancellor of the exchequer Pitt never had less than six thousand a year, besides an excellent house. In 1792 he was forced by his royal master's friendly importunity to accept for life the office of warden of the Cinque Ports, with near four thousand a year more. He had neither wife nor child; he had no needy relations; he had no expensive tastes; he had no long election bills. Had he given but a quarter of an hour a week to the regulation of his household, he would have kept his expenditure within bounds. Or, if he could not spare even a quarter of an hour a week for that purpose, he had numerous friends, excellent men of business, who would have been proud to act as his stewards. One of those friends, the chief of a great commercial house in the city, made an attempt to put the establishment in Downing Street to rights, but in vain. He found that the waste of the servants' hall was almost fabulous. The quantity of butcher's meat charged in the bills was nine hundredweight a week. The consumption of poultry, of fish, of tea, was in proportion. The character of Pitt would have stood higher if with the disinterestedness of Pericles and of De Witt he had united their dignified frugality.

The memory of Pitt has been assailed, times innumerable, often Estimates justly, often unjustly; but it has suffered much less from his of Pitt. assaults than from his eulogists. For, during many years, his name was the rallying cry of a class of men with whom, at one of those terrible conjunctures which confound all ordinary distinctions, he was accidentally and temporarily connected, but to whom, on almost all great questions of principle, he was diametrically opposed. The hnters of parliamentary reform called themselves Pittites, not choosing to remember that Pitt made three motions for parliamentary reform, and that, though he thought that such a reform could not safely be made while the passions excited by the French Revolution were raging, he never uttered a word indicating that he should not be prepared at a more convenient season to bring the question forward a fourth time. The toast of Protestant ascendancy was drunk on Pitt's birthday by a set of Pittites who could not but be aware that Pitt had resigned his office because he could not carry Catholic emancipation. The defenders of the Test Act called themselves Pittites, though they could not be ignorant that Pitt had laid before George III. unanswerable reasons for abolishing the Test Act. The enemies of free trade called themselves Pittites, though Pitt was far more deeply imbued with the doctrines of Adam Smith than either Fox or Grey. The very negro-drivers invoked the name of Pitt, whose eloquence was never more conspicuously displayed than when he spoke of the wrongs of the negro. This mythical Pitt, who resembles the genuine Pitt as little as the Charlemagne of Ariosto resembles the Charlemagne of Eginhard, has had his day. History will vindicate the real man from calumny disguised under the semblance of adulation, and will exhibit him as what he was—a minister of great talents, honest intentions, and liberal opinions, pre-eminently qualified, intellectually and morally, for the part of a parliamentary leader, and capable of administering with prudence and moderation the government of a prosperous and tranquil country, but unequal to surprising and terrible emergencies, and liable in such emergencies to err grievously, both on the side of weakness and on the side of violence. (31.)

PITTA, in Ornithology, from the Telegu *Pitta*, meaning a small Bird, Latinized by Vieillot in 1816 (*Analyse*, p. 42) as the name of a genus, and since adopted by English ornithologists as the general name for a group of Birds, called by the French *Brèrs*, and remarkable for their great beauty.<sup>2</sup> For a long while the Pittas were commonly supposed to be allied to the *Turdidæ*, and some English

<sup>1</sup> Henry Petty Fitzmaurice, third marquis of Lansdowne, was born in London, July 2, 1764, and died at Bowood, January 31, 1863. He entered parliament in 1801, and succeeded to the peerage in 1809. For a brief period in 1823 he was secretary of state for the home department, and again, in 1828-29, secretary for the colonies. From 1831 to 1841, and from 1846 to 1852, he was lord president of the council.]

<sup>2</sup> In Ornithology the word is first found as part of the native name, "Pon-nunky pitta," of a Bird, given in 1713 by Petiver, in the "Mantissa" in Ray's *Synopsis* (p. 125), on the authority of Buckley (see ORNITHOLOGY, vol. xviii, p. 5, note 1). This bird is the *Pitta bengalensis* of modern ornithologists, and is said by Jerdon (*Birds of India*, I. p. 503) now to bear the Telegu name of *Pona-lukki*.

funeral.

writers applied to them the name of "Water-Thrushes" and "Ant-Thrushes," though there was no evidence of their having aquatic habits or predilections, or of their preying especially upon ants; but the fact that they formed a separate Family was gradually admitted. Their position was at last determined by Garrod, who, having obtained examples for dissection, in a communication to the Zoological Society of London, printed in its *Proceedings* for 1876, proved (pp. 512, 513) that the *Pittidæ* belonged to that section of Passerine Birds which he named *Mesomyodi* (ORNITHOLOGY, vol. xviii. p. 41), since their syrinx, like that of the *Tyrannidæ* (KING-BIRD, vol. xiv. p. 80), has its muscles attached to the middle of its half-rings, instead of to their extremities as in the higher Passerines or *Acromyodi*. This in itself was an unexpected determination, for such a structure had been thought to be confined to Birds of the New World, to which none of the *Pittas* belong. But it is borne out by, and may even serve to explain, the sporadic distribution of the latter, which seems to point them out as survivors of a somewhat ancient and lower type of *Passeres*. Indeed except on some theory of this kind the distribution of the *Pittas* is almost unaccountable. They form a very homogeneous

*Pitta elegans*, male and female.

Family, not to say genus, which it is not easy to split up justifiably, for all its members bear an unmistakable and close resemblance to each other—though the species inhabit countries so far apart as Angola and China, India and Australia; and, to judge from the little that has been recorded, they are all of terrestrial habit, while their power of flight, owing to their short wings, is feeble. Nearly fifty species have now been described, most of them found in the Malay Archipelago, between the eastern and western divisions of which they are pretty equally divided; and, in Mr Wallace's opinion,<sup>1</sup> they attain their maximum of beauty and variety in Borneo and Sumatra, from the latter of which islands comes the species, *Pitta elegans*, represented in the accompanying woodcut. Few Birds can vie with the *Pittas* in brightly-contrasted coloration. Deep velvety black, pure white, and intensely vivid scarlet, turquoise-blue and beryl-green—mostly occupying a considerable extent of surface—are found in a great many of the species,—to say nothing of other composite or intermediate hues; and, though in some a modification of these tints is observable, there is scarcely a trace of any blending of shade, each patch of colour standing out distinctly.

<sup>1</sup> Owing to recent discoveries in Papuasia it is possible that this opinion may require some modification.

This is perhaps the more remarkable as the feathers have hardly any lustre to heighten the effect produced, and in some species the brightest colours are exhibited by the plumage of the lower parts of the body. *Pittas* vary in size from that of a Jay to that of a Lark, and generally have a strong bill, a thickset form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little or no external difference between the sexes. All the species then known were figured in Mr Elliot's *Monograph of the Pittidæ*, completed in 1863; but so many have since been described that this work but imperfectly represents the existing knowledge of the Family, and even Schlegel's revised catalogue of the specimens contained in the Leyden Museum (*Mus. des Pays-Bas*, livr. 11), published in 1874, is now out of date, so that a new synopsis is very desirable. Many of the lately-discovered species have been figured in Gould's *Birds of Asia* and *Birds of New Guinea*.

Placed by some authorities among the *Pittidæ* is the genus *Philepitta*, consisting of two species peculiar to Madagascar, while other systematists would consider it to form a distinct Family. This last is the conclusion arrived at by W. A. Forbes (*Proc. Zool Society*, 1880, pp. 387-391) from its syringeal characters, which, though shewing it to be allied to the *Pittas*, are yet sufficiently different to justify its separation as the type of a Family *Philepittidæ*. The two species which compose it have little outward resemblance to the *Pittas*, not having the same style of coloration and being apparently of more arboreal habits. The sexes differ greatly in plumage, and the males have the skin round the eyes bare of feathers and carunculated.

It may be advisable to remark that nomenclatorial purists, objecting to the names *Pitta* and *Philepitta* as "barbarous," call the former *Coloburis* and the latter *Paictes*. *Brachyurus* also has frequently been used for *Pitta*; but, having been previously applied in another sense, it is inadmissible. (A. N.)

PITTACUS of Mytilene in Lesbos, one of the seven sages of Greece, was born in 651 B.C. His father Hyrradius (or Caicus) was a Thracian, his mother was a Lesbian. About 611 B.C. Pittacus, along with the brothers of the poet Alcæus, overthrew Melanchrus, tyrant of Lesbos. In a war between the Mytilenians and Athenians for the possession of the town of Sigeum on the Hellespont, Pittacus, as general of the Mytilenians, slew the Athenian commander Phrynon in single combat, having entangled him in a net (606 B.C.). In 589 his fellow-citizens entrusted Pittacus with despotic power for the purpose of protecting them against the exiled nobles, at the head of whom were Alcæus and Antimenides. Pittacus effected this object, and, without introducing a new constitution, contrived by legislation to restore the existing constitution to regular working order. One of his laws enacted that offences committed during intoxication should be punished with double severity. For the historian of the law of inheritance some interest attaches to the enactment of Pittacus that father and mother should succeed, in equal shares, to the property of a deceased child. He resigned the government after holding it for ten years, and died ten years later (569 B.C.).

The stories which bring Pittacus and Croesus into connexion are probably mere legend, since Croesus was only twenty-five years of age at the date of Pittacus's death. Pittacus was regarded as a pattern of all the virtues, and this high character is borne out by what we know of him. When Alcæus, who had bitterly assailed him in his poems, fell into his hands, he let him go, saying that forgiveness was better than revenge. Of the lands which his grateful countrymen would have bestowed on him he accepted only a small part. Amongst the sayings attributed to him are these:—it is hard to be good; rule reveals the man; the best rule is that of law; speak ill neither of friend nor foe. Pittacus was also a poet; Diogenes Laërtius states that he composed six hundred elegiac verses.

PITTSBURGH, the second largest city of Pennsylvania, and the leading iron, steel, and glass manufacturing centre of the United States, lies at the confluence of the Allegheny and the Monongahela, which unite here to form the Ohio, 250 miles west by north of Philadelphia. The business quarter of the city is built on a nearly level triangular plain, between the two rivers, measuring about three quarters of a mile on each side back to the hills which rise to the east.

The manufacturing establishments stretch for a distance of 7 miles up the Allegheny, 7 up the Monongahela, and 2 down the Ohio, and occupy the strip of low ground usually a few hundred feet broad between the river banks and the hills which generally face them. The slope of the hills to the east of the business quarter is closely built with residences and retail stores for the distance of a mile and a half, but the summits, 400 or 500 feet high, are partially unoccupied. Beyond the hills extends a rolling country which, for a space of about 5 miles long by 2 wide is occupied by the villas of the citizens. The hills facing the rivers are generally precipitous, and vary in height from 300 to 600 feet, but at different points they recede from the river banks and afford sites for the

the city is obtained from a view of the suburban quarters of the East End and the parks and residence quarters of Allegheny. And, all disfigurement and dirtiness notwithstanding, it is full of interesting and striking sights. The interiors of its rolling-mills and glass-houses, and the views of the city from the surrounding hills, with the manufacturing quarters marked out by their smoke by day and their fires by night, are of a unique and picturesque character. Along the rivers are fleets of steamers towing barges laden with coal for consumption at this point and for shipment to the cities lower down. Joining the various quarters of the city are ten bridges for ordinary traffic and four railway viaducts, among which the Point Bridge and the Smithfield Street Bridge are fine examples of engineering in iron. Six inclined-plane railways afford access to the summits of the high hills.

Pittsburgh is of historical interest from the struggle (1755-1758) for its possession between England and France in the Seven Years' War, and the fact that the public and military career of George Washington was commenced with those campaigns (see WASHINGTON). With the termination of that struggle in the capture of the ruins of Fort Duquesne by the British, the history of the place becomes that of an ordinary frontier town. A new fort was erected and named Fort Pitt in honour of the prime minister whose energy

had urged the war forward to its capture, and wrested the Ohio valley and Canada from French control. After one or two Indian wars, in which the post was threatened, and on one occasion nearly taken, Fort Pitt lost its military character and became a trading town. The first streets were laid out near the fort in 1764, and in 1769 the first survey of the unsettled lands in the vicinity was made for the proprietors, the heirs of William Penn, under the name of the manor of Pittsburgh. After the termination of the revolution, the legislature of Pennsylvania incorporated Pittsburgh as a village on April 22, 1794, and on March 18, 1816, its charter as a city was granted. During the colonial period a dispute arose between Virginia and Pennsylvania as to the possession of the territory surrounding the town, and in the first few years of its history under the United States it attracted attention from its proximity to the famous "Whisky Insurrection" of Western Pennsylvania. After it had attained a population of 30,000 it was visited on the 10th of April 1845 by a disastrous conflagration in which the buildings in the business centre, covering a space of 56 acres, and valued at \$5,000,000 dollars, were consumed.

In the Pittsburgh of to-day there is little besides names of streets, hills, and suburbs to recall the struggle which decided the Anglo-Saxon character of the country. The locality known as the Point, where Fort Duquesne stood, is covered with thickly built factories and dingy tenements. In a squalid and obscure court a portion of the wall of a blockhouse erected in 1763 by Colonel Boquet, one of the British commandants of Fort Pitt, still forms a part of a building, and on the wall of the staircase of Municipal Hall is a stone bearing the inscription with which that officer commemorated its erection. Immediately across the Monongahela a range of precipitous hills some 500 feet high bears the names of Mount Washington and Duquesne Heights. On the first hill rising to the east of the level part of the city, a red granite courthouse, to cost \$2,000,000, is in process of construction near to the spot where Major Grant was defeated and slain, and the new building will replace the brown stone structure which for many years fronted on the street bearing that unfortunate officer's name. Twelve miles away, the suburb long known as Braddock's Field and now as Braddock's, attracts attention chiefly by the roar and glare of its great steel manufacturing establishment.

Deriving its early importance in commerce from its position at the head of the Ohio, which was until 1855 the principal route between the middle States and the west and south-west, Pittsburgh has since obtained its greatest growth from the coal which underlies nearly all Western Pennsylvania. This has made the city and its immediate suburbs the most important manufacturing district in America, in both pig and bar iron, steel, glass, and copper. In 1883 Allegheny county produced 11½ per cent. of the pig iron produced in the United States, and 21 per cent. of the rolled iron and steel. The iron industry consists of 16 blast furnaces, producing, in 1883, 592,475 tons; 32 rolling mills, producing 472,351

Plan of Pittsburgh.

suburbs of Lawrenceville (on the Allegheny), Hazelwood, and Birmingham (on the north and south banks respectively of the Monongahela), which are within the municipality of Pittsburgh, and (on the north bank of the Allegheny and Ohio) for the city of Allegheny, which, with its separate municipal government and population of 78,000 inhabitants, is commercially and socially a part of Pittsburgh. The two cities together cover an irregular space of 9 miles between the extreme eastern and western points, with a breadth varying from 2 to 4 miles.

From the character of its site Pittsburgh would naturally be very attractive, but the free use of the bituminous coal which has been the principal agent in its development has so spoiled its beauty as to give it the name of the Smoky City. Not only do the manufacturing quarters show long lines of smoke-stained buildings, but the business quarter, which is composed of rather narrow streets laid out early in the century, is mainly constructed of brick and iron, and in spite of the presence of some fine public buildings in granite and brown stone—the municipal hall, the petroleum exchange, the new United States post office and court-house (1881), the new county court-house (1881), &c.—has a generally grimy and unattractive appearance. A better opinion of the wealth and taste of

tons of finished iron; and 91 other establishments, turning out a large variety of other manufactures of iron, from boilers to safes and steam pumps. The steel industry comprises 20 large mills with an output for 1883 of 405,530 tons. The blast furnaces and rolling-mills of Pittsburgh employ a capital of \$23,910,000 and 21,190 workmen, the steel industry \$10,170,000 and 7080 workmen. Next in importance is the glass manufacture, in which 75 establishments are engaged, 21 making table ware, 24 window glass, 10 green glass bottles, and 9 lamp chimneys. The capital invested in them is \$5,935,000. They employ 6142 hands, and the value of their last reported annual production is \$5,832,653. The coal and coke industry of the district, which is controlled mainly by Pittsburgh, comprises a capital of \$26,406,500, employs 23,621 miners and other labourers, and makes an annual output of 7,729,099 tons of coal and 2,760,000 tons of coke, valued at \$16,600,000. The total of all the manufacturing industries of the city is 1380 establishments, with \$105,191,481 of capital, employing 85,936 workmen of all kinds, and producing to the value of \$119,721,619. The whole-sale trade of the city is much less important than its manufacturing industries, and with a few exceptions is confined to the immediate vicinity. It includes 90 firms with an aggregate capital of \$11,206,060 and total sales of \$125,390,472. Within the last year a new and unique industry has been developed. By drilling in the earth to a depth of 1200 to 2000 feet, what is practically the fire damp of the coal mine is tapped in such quantity that it comes to the surface in great force. It has been found to be useful as a fuel for all the purposes of coal except the smelting of ores in blast furnaces; and, as it is cheaper both for making steam and for the heating of the iron and glass furnaces, its adoption has been general among the manufacturers.

As the railway system has developed, the important boating interest of Pittsburgh has become confined to the transportation of coal from the Monongahela river mines to the down-river cities. The coal is only taken out when freshets have raised the river, and at that time fleets of steamers, each towing from eight to fifteen barges, covering acres in extent and carrying thousands of tons of coal, start down stream. The total steam tonnage of Pittsburgh is 36,815 tons with 163 vessels, but the addition of the barges brings the tonnage up to 1,359,972 and the number of vessels to 3203.

Pittsburgh is stated to be the origin of more railway freight than any other point in the country. There are a large number of lines, under the control of three great companies. The most important is the Pennsylvania Railroad, whose trunk lines pass through the city, and number among their feeders the West Pennsylvania; the Allegheny Valley; the Pittsburgh, Virginia, and Charleston; the Pittsburgh, Cincinnati, and St. Louis; the Pittsburgh, Fort Wayne, and Chicago; and the Cleveland and Pittsburgh Railroads. The Pittsburgh division of the Baltimore and Ohio Railroad gives a connexion with that trunk line, and by the Pittsburgh and Western, and the Pittsburgh, Cleveland, and Toledo, reaches the Chicago branch of the same system to the west. The Pittsburgh and Lake Erie affords the New York Central and the New York, Pennsylvania, and Ohio lines an access to Pittsburgh, while its extension under the name of the Pittsburgh, McKeesport, and Youghiogheny penetrates the coal and coke district to the south-east.

In 1796, by the first accurate census on record, the population of Pittsburgh was 1335. By 1810 it had increased to 4963; by 1820 to 7248; by 1830 to 12,152; by 1840 to 21,115; by 1850 to 36,601; by 1860 to 49,221; by 1870 to 86,076. In 1871 the consolidation of outlying boroughs made the population, according to the census of 1870, 121,799; and in 1880 this had increased to 156,389. These figures do not comprise the population of Allegheny, which was 23,792 in 1860, 53,150 in 1870, and 78,682 in 1880. Including the manufacturing and residential suburbs, the total population by the census of 1880 was 274,160; and, with the large extension of manufacturing and building that has gone on since then, it was estimated in 1884 at 325,000.

The municipal governments of Pittsburgh and Allegheny are each composed of a mayor, controller, and treasurer, with city councils in two branches styled respectively select and common. These are elected by the people, and appoint other administrative officials to take charge of the police and fire departments, assessments, and public works. The total assessed valuation of the city of Pittsburgh for purposes of taxation is \$101,508,603, on which a revenue is collected for all purposes of \$2,777,405. Allegheny has an assessed valuation of \$10,707,853, and spends \$650,000 annually. The total indebtedness of Pittsburgh is \$14,497,800, of which nearly \$10,000,000 was expended for water-works and street pavements. The debt of Allegheny is but \$1,400,000.

The school system of each city is governed by a central board of education and ward boards, both elected by popular vote. The Pittsburgh system comprises a fine stouck high school overlooking the city, and 52 ward schools, in which are 469 teachers and 23,629 scholars, the approximate annual expenditure being \$550,000. In the Allegheny system there are the high school

and 18 ward schools, with 207 teachers, 9392 scholars, and an annual expenditure of about \$200,000. The principal institutions established by public taxation are the Riverside State Penitentiary, completed in 1884 in the lower part of Allegheny; the Morgantza Reform School; the workhouse at Claremont, on the Allegheny river; and the Pittsburgh, Allegheny, and County poorhouses.

The churches and chapels in Pittsburgh and Allegheny number 237: 57 are Roman Catholic, including 13 monastic and conventual establishments; 53 represent the various branches of Presbyterianism; 39 are Methodist Episcopal, and 16 Protestant Episcopal. Among the leading examples of church architecture are St Paul's Cathedral (Roman Catholic), Trinity and St Peter's (Protestant Episcopal), the First and Third Presbyterian and the German Lutheran churches in Pittsburgh, and the North Presbyterian in Allegheny. Private charity has established the West Penn. Hospital with a large branch for the treatment of the insane at Dixmont, the Homeopathic Hospital, the Mercy Hospital, the Pittsburgh Infirmary, the Free Dispensary, the North Side Hospital, and St Francis Hospital; and 18 asylums for orphans and the aged and infirm are maintained throughout the two cities. The collegiate institutions comprise the Western University, the Western Theological Seminary (Presbyterian), the United Presbyterian Seminary, the Catholic College, the Pennsylvania Female College, and the Pittsburgh Female College. (J. F. H.)

PITTSFIELD, a borough and township of the United States, the shire town of Berkshire county, Massachusetts, lies at a height of from 1000 to 1200 feet above the sea on a plain between the Hoosacs on the east and the Taconics on the west. It is traversed by the headwaters of the Housatonic and Hoosac rivers, and derives its supply of drinking water from Lake Ashley, a romantic loch on the top of the Washington Hills, 7 miles to the south-east. As the northern terminus of the Housatonic Railroad, and a junction on the Boston and Albany and the Pittsfield and North Adams Railroads, it is an important centre of traffic. Most of the dwelling houses are built of wood. Among the public edifices are a court-house, in white marble; the Berkshire Athenæum, with a free library and reading-room; the Roman Catholic church of St Joseph, in marble; the Methodist church, a spacious edifice of brick; the First Congregational church (rebuilt in 1853), for thirty years under the charge of Rev. John Todd, author of the *Student's Manual*; and the Maplewood Institute for young ladies. The Berkshire Medical Institute (1822) ceased to exist in 1869. There is a small park with a fine soldiers' monument (1872) in the heart of the town, as well as a larger park with a race-course in the eastern suburb. Cotton and woollen goods, silk, knit goods, shoes, and tacks are among the local manufactures. The population in 1860 was 8045; in 1870, 11,132; in 1880, 13,361. Pittsfield, which once formed part of the Indian domain of Pontoosuc, and for a time was known as Boston Plantation, was incorporated in 1761, and received its present name in honour of the earl of Chatham. Oliver W. Holmes long resided on a small farm two miles south of Pittsfield.

PITTSTON, a borough of the United States, in Luzerne county, Pennsylvania, on the east bank of the Susquehanna, just below the confluence of the Lackawanna, 105 miles north by west of Philadelphia. It is the centre of the Wyoming anthracite region and the seat of the Pennsylvania Coal Company's operations, contains knitting mills, planing mills, terra cotta works, a stove factory, lumber yards, &c., and commands four distinct railway lines. The population was 6760 in 1870 and 7472 in 1880. If West Pittston (a borough on the other side of the Susquehanna, with which Pittston communicates by two bridges) were included, the total would be 10,016.

PIUS I. Hardly anything is known with certainty respecting Pius I., except that he was bishop of Rome from 158 to 167 A.D. He is said to have been born at Aquileia and to have been the son of a certain Rufinus; it is added that he suffered martyrdom, but, although

he is celebrated as a martyr in the breviary, there seems no other evidence for this assertion. A few letters extant under his name are spurious.

PIUS II. (Enea Silvio Piccolomini, commonly known in literature as Æneas Sylvius), pope from 1458 to 1464, "whose character reflects almost every tendency of the age in which he lived," was born at Corsignano in the Sienese territory, October 18, 1405, of a noble but decayed family. After studying at the universities of Siena and Florence, he settled in the former city as a teacher, but in 1431 accepted the post of secretary to Domenico Capranica, bishop of Fermo, then on his way to Basel to protest against the injustice of the new pope Eugenius IV. in refusing him the cardinalate for which he had been designated by Martin V. Arriving at Basel after numerous adventures, he successively served Capranica and several other masters. In 1435 he was sent by Cardinal Albergata, Eugenius's legate at the council, on a secret mission to Scotland, the object of which is variously related, even by himself. He visited England as well as Scotland, underwent many perils and vicissitudes in both countries, and has left a valuable account of each. Upon his return he sided actively with the council in its conflict with the pope, and, although still a layman, obtained a leading share in the direction of its affairs. But when in 1442 the council elected Amadeus, duke of Savoy, as an antipope under the name of Felix V., Æneas, perceiving that the step was generally disapproved, found a pretext for withdrawing to the emperor Frederick III.'s court at Vienna. He was there crowned imperial poet laureate, and obtained the patronage of the emperor's chancellor, Kaspar Schlick, a love adventure of whose at Siena he celebrated in his romance, *Eurialus and Lucretia*. His character had hitherto been that of an easy man of the world, with no pretence to strictness in morals or consistency in politics. He now began to be more regular in the former respect, and in the latter adopted a decided line by making his peace with Rome. Being sent on a mission to Rome in 1445, with the ostensible object of inducing Eugenius to convoke a new council, he was absolved from ecclesiastical censures, and returned to Germany under an engagement to assist the pope. This he did most effectually by the diplomatic dexterity with which he smoothed away differences between the court of Rome and the German electors; and he had a leading part in the compromise by which, in 1447, the dying Eugenius accepted the reconciliation tendered by the German princes, and the council and the antipope were left without support. He had already taken orders, and one of the first acts of Eugenius's successor Nicholas V. was to make him bishop of Trieste. In 1450 he was sent ambassador by the emperor Frederick to negotiate his marriage with the Princess Leonora of Naples, which object he successfully achieved; in 1451 he undertook a mission to Bohemia, and concluded a satisfactory arrangement with the Hussite chief George Podiebrad; in 1452 he accompanied Frederick to Rome, where the emperor wedded Leonora and was crowned king of the Romans. In August 1455 Æneas again arrived in Rome on an embassy to proffer the obedience of Germany to the new pope, Calixtus III. He brought strong recommendations from the emperor and King Ladislaus of Hungary for his nomination to the cardinalate, but delays arose from the pope's resolution to promote his own nephews first, and he did not attain the object of his ambition until December in the following year.

Calixtus III. died on August 6, 1458. On August 10 the cardinals entered into conclave. The wealthy cardinal of Rouen, though a Frenchman and of exceptionable character, seemed certain to be elected. Æneas has told us in a passage of his own history of his times, long

retrenched from that work but printed clandestinely in the *Conclavi de' Pontifici Romani*, by what art, energy, and eloquence he frustrated this false step. It seemed but meet that the election should fall upon himself: no other candidate appears to have been seriously thought of; nor, although the sacred college probably included a few men of higher moral standard, had it any on the whole so worthy of the tiara. It was the peculiar faculty of Æneas to accommodate himself perfectly to whatever position he might be called upon to occupy; it was his peculiar good fortune that every step in life had placed him in circumstances appealing more and more to the better part of his nature, an appeal to which he had never failed to respond. The party pamphleteer had been more respectable than the private secretary, the diplomatist than the pamphleteer, the cardinal than the diplomatist; now the unscrupulous adventurer and licentious novelist of a few short years ago seated himself quite naturally in the chair of St Peter, and from the resources of his versatile character produced without apparent effort all the virtues and endowments becoming his exalted station. After allying himself with Ferdinand, the Aragonese claimant of the throne of Naples, his next important act was to convene a congress of the representatives of Christian princes at Mantua for joint action against the Turks. His long progress to the place of assembly resembled a triumphal procession; and the congress, a complete failure as regarded its ostensible object, at least showed that the impotence of Christendom was not owing to the pope. On his return from the congress Pius spent a considerable time in his native district of Siena, and has described his delight and the charms of a country life in very pleasing language. He was recalled to Rome by the disturbances occasioned by Tiburzio de Maso, who was ultimately seized and executed. The papal states were at this time greatly troubled by rebellious barons and marauding condottieri, but these evils gradually abated. The Neapolitan war was also terminated by the success of the pope's ally Ferdinand. In July 1461 Pius canonized St Catherine of Siena, and in October of the same year he gained what at first appeared to be a most brilliant success by inducing the new king of France, Louis XI., to abolish the pragmatic sanction, by which the pope's authority in France had been grievously impaired. But Louis had expected that Pius would in return espouse the French cause in Naples, and when he found himself disappointed he virtually re-established the pragmatic sanction by royal ordinances. Pius was also engaged in a series of disputes with the Bohemian king and the count of Tyrol, and the crusade for which the congress of Mantua had been convoked made no progress. The pope did his best: he addressed an eloquent letter to the sultan urging him to become a Christian; he succeeded in reconciling the emperor and the king of Hungary, and derived great encouragement as well as pecuniary advantage from the discovery of mines of alum in the papal territory. But France was estranged; the duke of Burgundy broke his positive promise; Milan was engrossed with the attempt to seize Genoa; Florence cynically advised the pope to let the Turks and the Venetians wear each other out. Pius was unawares nearing his end, and his malady probably prompted the feverish impatience with which on June 18, 1464, he assumed the cross and departed for Ancona to conduct the crusade in person. It seemed certain that the issue of such an enterprise could only be ridiculous or disastrous. Pius II.'s good genius again stepped in, and rendered it pathetic. He was suffering from fever when he left Rome. The crusading army melted away at Ancona for want of transport, and when at last the Venetian fleet arrived the dying pope could only view it from a window. He expired two days afterwards, August

14, 1464, in his death as in his life a figure picturesque and significant far beyond the wont of Roman pontiffs. He was succeeded by Paul II.

Pius, indeed, regarded as a man and not merely as an historical personage, is the most interesting of all the successors of St Peter. It is easy to take his character to pieces, but the aroma of something exquisite lingers around every fragment. He had a healthy, sincere, loving nature, frank and naïve even in his aberrations and defects, which seem after all sufficiently venial. The failings of other popes have most frequently been those of the priest, and therefore in the true sense of the term inhuman. It is a refreshing transition to the faults of the adventurer, the diplomatist, the man of letters and pleasure. The leading trait of Pius's character was his extreme impressionableness. Chameleon-like he took colour from surrounding circumstances, and could always depend on being what these circumstances required him to be. As, therefore, his prospects widened and his responsibilities deepened, his character widened and deepened too; and he who had entered upon life a shifty adventurer quitted it a model chief shepherd. His virtues were not only great, but the most conspicuous were those especially characteristic of the finer natures. While he vied with any man in industry, prudence, wisdom, and courage, he excelled most men in simplicity of tastes, constancy of attachments, kindly playfulness, magnanimity, and mercy. As chief of the church he was able and sagacious, and showed that he comprehended the conditions on which its monopoly of spiritual power could for a season be maintained; his views were far-seeing and liberal; and he was but slightly swayed by personal ends. He is especially interesting as the type of the scholar and publicist who wins his way by intellectual strength, foreshadowing the age to come when the pen should be mightier than the sword; and no less as the figure in whom the mediæval and the modern spirit are most distinctly seen to meet and blend, ere the latter definitively gains the mastery.

Pius was a versatile and voluminous author, one of the best and most industrious of his period. His most important work is his *Commentaries of his own Times*, published in 1534 under the name of Gobelinus, to whom it has been ascribed, but who was in fact only the copyist. It appears to have been altered to some slight extent by his secretary Campanus. Numerous passages suppressed at the time of publication have been recently published in the *Transactions of the Accademia de' Lincei* by Signor Cugnone, together with other inedited works. Pius's *Commentaries* are delightful reading, and their historical value is very great. "Pius II.," says Creighton, "is the first writer who attempted to represent the present as it would look to posterity, who consciously applied a scientific conception of history to the explanation and arrangement of passing events." His *Epistles*, which were collected by himself, are also an important source of historical information. The most valuable of his minor historical writings are his histories of Bohemia and of the emperor Frederick III., the latter partly autobiographical. He sketched geographical treatises on Europe and Asia, and in early and middle life produced numerous tracts on the political and theological controversies of his day, as well as on ethical subjects. Pius was greatly admired as a poet by his contemporaries, but his reputation in belles lettres rests principally upon his *Eurialus* and *Lucretia*, which continues to be read to this day, partly from its truth to nature, and partly from the singularity of an erotic novel being written by a pope. He also composed some comedies, one of which alone is extant, and as yet only in MS. All these works are in Latin. Pius was not an eminent scholar: his Latin is frequently incorrect, and he knew little Greek; but his writings have high literary qualities, and will always be prized as vivid and accurate reproductions of the spirit of a very remarkable age.

All the chief authorities for Pius's life are sifted and condensed in the admirable biography by Voigt (3 vols., Berlin, 1856-63). Professor Creighton, in his *History of the Papacy during the Reformation* (vol. II., Lond. n, 1882), has given the English reader the substance of Voigt's narrative, while preserving a full independence of judgment. (R. G.)

PIUS III. (Francesco Todeschini), pope from September 22 to October 18, 1503, was born at Siena, May 9, 1439. As the nephew of Pius II. by his sister Laodamia, he was

received into favour by that pontiff, who permitted him to assume the name and arms of the Piccolomini, and raised him, when only twenty-two years of age, to the see of Siena and the cardinalate. He was employed by subsequent popes in several important legations, as by Paul II. at the diet of Ratisbon, and by Sixtus IV. to secure the restoration of ecclesiastical authority in Umbria. Amid the disturbances consequent upon the death of Alexander VI. he was, by the not wholly disinterested influence of Cardinal Rovera, elected pope on September 22, 1503, his installation taking place on the 8th October following. He at once took in hand the reform of the papal court and arrested Cæsar Borgia; but after a brief pontificate of twenty-six days he died (October 18, 1503) of an ulcer in the leg, or, as some have alleged, of poison administered at the instigation of Pandolfo Petrucci, governor of Siena. He was succeeded by Julius II.

PIUS IV. (Giovanni Angelo Medici), pope from 1559 to 1565, was born of humble parentage at Milan, March 31, 1499. His early career connects itself in some measure with the romantic rise of his elder brother from the position of bravo to that of Marchese di Marignano. After studying at Bologna and acquiring reputation as a jurist, he went in 1527 to Rome, and as the favourite of Paul III. was rapidly promoted to the governorship of several towns, the archbishopric of Ragusa, the vice-legateship of Bologna, and in April 1549 to the cardinalate. On the death of Paul IV. he was elected pope on December 28, 1559, and installed on the 6th January 1560. His first public acts of importance were to grant a general pardon to the participators in the riot which had closed the previous pontificate, and to bring to trial the nephews of his predecessor, of whom Cardinal Carlo Caraffa was strangled, and the duke Paliano, with his nearest connexions, beheaded. On the 18th January 1562 the council of Trent, which had been suspended by Julius III., was opened for the third time. Great skill and caution were necessary to effect a settlement of the questions before it, inasmuch as the three principal nations taking part in it, though at issue with regard to their own special demands, were prepared to unite their forces against the demands of Rome. Pius, however, aided by Morone and Borromeo, proved himself equal to the emergency, and by judicious management and concession brought the council to a termination satisfactory to the disputants and favourable to the pontifical authority. Its definitions and decrees were confirmed by a bull dated January 26, 1564; and, though they were received with certain limitations by France and Spain, the famous Creed of Pius IV., or Tridentine Creed, remained the authoritative expression of the Catholic faith. The more marked manifestations of stringency during his pontificate appear to have been prompted rather than spontaneous, his personal character inclining him to moderation and ease. Thus a monitory, issued in 1564, summoning the queen of Navarre before the Inquisition on a charge of Calvinism, was withdrawn by him in deference to the indignant protest of Charles IX.; and in the same year he published a bull granting the use of the cup to the laity of Austria and Bohemia. One of his strongest passions appears to have been that of building, which somewhat strained his resources in contributing to the adornment of Rome, and in carrying on the work of restoration, erection, and fortification in various parts of the ecclesiastical states. A conspiracy against him, headed by the Catholic fanatic Benedetto Accolti, was discovered and crushed in 1565. He died shortly afterwards, on December 9th of that year, and was succeeded by Pius V.

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born at Bosco in the duchy of Milan, January 17,

1504. At the age of fourteen he entered the Dominican order, passing from the monastery of Voghera to that of Vigevano, and thence to Bologna. Having been ordained priest at Genoa in 1528, he settled at Pavia, where he lectured for sixteen years. He soon gave evidence of the opinions which found a more practical expression in his pontificate, by advancing at Parma thirty propositions in support of the papal chair and against the heresies of the time. As president of more than one Dominican monastery he proved himself a rigid disciplinarian, and, in accordance with his own wish to discharge the office of inquisitor, received an appointment to that post at Como. His zeal provoking resentment, he was compelled in 1550 to return to Rome, where, after having been employed in several inquisitorial missions, he was elected to the commissariat of the Holy Office. Paul IV., who while still Cardinal Caraffa had shown him special favour, conferred upon him the bishopric of Sutri and Nepi, the cardinalate with the title of Alessandrino, and the honour—unique in one not of pontifical rank—of the supreme inquisitorship. Under Pius IV. he became bishop of Mondovì in Piedmont, but his opposition to that pontiff procured his dismissal from the palace and the abridgment of his authority as inquisitor.

Before Ghislieri could return to his episcopate, Pius IV. died, and on January 7, 1566, he was elected to the papal chair with duly attendant prodigies, his coronation taking place on his birthday, ten days later. Fully alive to the necessity of restoring discipline and morality at Rome to ensure success without, he at once proceeded to reduce the cost of the papal court, compel residence, regulate inns, expel prostitutes, and assert the importance of ceremonial. In his wider policy, which was characterized throughout by a stringency which tended to defeat its own ends, the maintenance and increase of the efficacy of the Inquisition and the enforcement of the canons and decrees of the Tridentine council had precedence over all other considerations. The prudence of Commendone alone saved him at the commencement of his pontificate from trouble with Germany, as in the general diet of the empire at Augsburg (March 26, 1566) Pius saw a threatened invasion of his own supremacy and was desirous of limiting its discussions. In France, where his influence was stronger, he directed the dismissal of Cardinal Odet de Coligny and seven bishops, nullified the royal edict tolerating the extra-mural services of the Reformers, introduced the Roman catechism, restored papal discipline, and strenuously opposed all compromise with the heretics—his exertions leading up in no small degree to the massacre of St Bartholomew. In the list of more important bulls issued by him the famous bull "In Cena Domini" (1568) takes a leading place; but amongst others throwing light on his character and policy there may be mentioned his prohibition of questuary (February 1567 and January 1570); the condemnation of Michael Baius, the heretical professor of Louvain (1567); the reform of the breviary (July 1568); the denunciation of the *dirum nefas* (August 1568); the banishment of the Jews from the ecclesiastical dominions except Rome and Ancona (1569); the injunction of the use of the reformed missal (July 1570); the confirmation of the privileges of the Society of Crusaders for the protection of the Inquisition (October 1570); the prohibition of discussions concerning the miraculous conception (November 1570); the suppression of the *Fratres Humiliati* for alleged profligacy (February 1571); the approbation of the new office of the Blessed Virgin (March 1571); the enforcement of the daily recitation of the canonical hours (September 1571); and the purchase of assistance against the Turks by offers of plenary pardon (March 1572). His antagonism to Elizabeth was shown, not only in the countenance lent by

him to Mary Stuart and those who sought in her name to deliver England "ex turpissima muliebris libidinis servitute," but in the publication of a bull, dated April 27, 1570, excommunicating Elizabeth and releasing her subjects from their allegiance. His energy was in no respect more favourably exhibited than in his persistent and successful endeavours to form a general league against the Turks, as the result of which the battle of Lepanto (Oct. 7, 1571) was won by the combined fleet under Colonna. Three national synods were held during his pontificate—at Naples under Cardinal Alfonso Caraffa (whose family had, after inquiry, been reinstated by Pius V.), at Milan under Carlo Borromeo, and at Mechlin. His death took place on May 1, 1572, and he was canonized by Clement XI. on May 24th 1712. He was succeeded by Gregory XIII.

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1799, was born at Cesena, December 27, 1717. After taking the degree of doctor of laws in 1735, he went to Ferrara and became the private secretary of Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753. His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV. who appointed him one of his secretaries and canon of St Peter's. In 1758 he was raised to the prelature and then to the treasurership of the apostolic chamber by Clement XIII., whose successor, Clement XIV. created him cardinal on the 26th April 1773. On the death of Clement XIV. and after protracted debate, Braschi was elected to the vacant see on the 15th February 1775. His assumption of the title Pius VI. even then recalled to the populace the verse current in the pontificate of Alexander VI. "*Semper sub Sextis perdita Roma fuit*," though his earlier acts gave fair promise of liberal rule and reform in the defective administration of the papal states. He showed discrimination in his benevolences, reprimanded Potenziari, the governor of Rome, for unsuppressed disorders, appointed a council of cardinals to remedy the state of the finances and relieve the pressure of imposts, called to account Nicolo Bischi for the expenditure of moneys intended for the purchase of grain, reduced the annual disbursements by the suppression of several pensions, and adopted a system of bounties for the encouragement of agriculture. The circumstances of his election, however, involved him in difficulties from the outset of his pontificate. He had received the support of the ministers of the crowns and the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief *Dominus ac Redemptor* (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the *zelanti*, who believed him secretly inclined towards Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. As the result of these complications, Pius was betrayed into a series of half measures which gave little satisfaction to either party. The case of Ricci and the other Jesuits imprisoned in the castle of St Angelo had scarcely been settled, by formal discountenance but informal relaxations and final release, before the question became an international one. Driven from devout Catholic countries, the members of the condemned society found an asylum under the rule of the heretic Frederick II. and the schismatic Catherine II., who welcomed them upon educational grounds. A long correspondence ensued in which both monarchs maintained their right, Catherine carrying the matter still further and wresting from Pius a series of important concessions. Even in countries acknowledging the papal authority practical protests arose which tended to its limitation. In Austria the social and ecclesiastical reforms undertaken by Joseph II. and his minister

Kaunitz touched the supremacy of Rome so nearly that in the hope of staying them Pius adopted the exceptional course of visiting Vienna in person. He left Rome on the 27th February 1782, and was magnificently received by the emperor, but his mission was unattended by any marked success. In Naples difficulties necessitating certain concessions in respect of feudal homage were raised by the minister Tannucci, and more serious disagreements arose with Leopold I. and Ricci, bishop of Pistoia and Prato, upon questions of reform in Tuscany. The outbreak of the French Revolution followed, and Pius in vain endeavoured to preserve the ecclesiastical discipline and property. The old Gallican Church was suppressed; the pontifical and ecclesiastical possessions in France were confiscated; and an effigy of himself was burnt by the populace at the Palais Royal. The murder of the Republican agent, Hugo Bassville, in the streets of Rome (January 1793) gave new ground of offence; the papal court was charged with complicity by the French Convention; and Pius threw in his lot with the league against France. In 1796 Napoleon invaded Italy, defeated the papal troops, and occupied Ancona and Loreto. Pius sued for peace, which was granted at Tolentino on the 19th February 1797; but on the 28th December of that year, in a riot created by some Italian and French revolutionists, General Duphot of the French embassy was killed and a new pretext furnished for invasion. General Berthier marched to Rome, entered it unopposed on February 10, 1798, and, proclaiming it a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on February 20th was escorted from the Vatican to Siena, and thence from place to place—in succession to Florence, Parma, Piacenza, Turin, Grenoble, and Valence, where he died six weeks later, on the night of the 28th August 1799. Pius VII. succeeded him.

The name of Pius VI. is associated with many and often unpopular attempts to revive the splendour of Leo X. in the promotion of art and public works,—the words "*Munificentia Pii VI. P.M.*," graven in all parts of the city, giving rise amongst his impoverished subjects to such satire as the insertion of a minute loaf in the hands of Pasquin with that inscription beneath it. He is best remembered in connexion with the establishment of the museum of the Vatican, commenced at his suggestion by his predecessor, and with the attempt to drain the Pontine Marshes. In the latter undertaking large sums were expended to such small purpose that the phrase "*Sono andate alle paludi Pontine*" passed into a proverb applied to funds employed in extravagant projects. The chief result was the restoration of the Appian Way by the removal of the additions of Trajan and Theodoric with later accumulations, and the erection of a new viaduct to Terracina upon the original road of Appius Claudius.

PIUS VII. (Gregorio Luigi Barnaba Chiaramonti), pope from 1800 to 1823, was born at Cesena on August 14, 1742. After studying at Ravenna, he entered the Benedictine monastery of St Mary in his native town, but was almost immediately sent by his superiors to Padua and to Rome for a further course of studies in theology. He then held various teaching appointments in the colleges of his order at Parma and at Rome. He was created an abbot of his order by Pius VI., who appointed him bishop of Tivoli on the 16th December 1782, and on February 14, 1785, raised him to the cardinalate and the see of Imola. At the death of Pius VI. the conclave met at Venice on the 1st December 1799, with the result that Chiaramonti was declared his successor on March 14, 1800, and crowned on the 21st of that month. In the following July he entered Rome, appointed Cardinal Consalvi secretary of state, and busied himself with administrative reforms. His attention was at once directed to the ecclesiastical anarchy of France, where, apart from the broad schism on the question of submission to the republican constitution, discipline had been so far neglected that a large pro-

portion of the churches were closed, dioceses existed without bishops or with more than one, Jansenism and marriage had crept into the ranks of the clergy, and indifference or hostility widely prevailed amongst the people. Encouraged by the intimation through Cardinal Martiniana of Napoleon's desire for the re-establishment of the Catholic religion in France, Pius appointed Caselli and Archbishop Spina to arrange a concordat with three nominees of Napoleon—Joseph Bonaparte, Cretet, and the Vendean priest Bernier. Difficulties having arisen, the aid of Consalvi was called in, and the concordat, signed at Paris on July 15th, was ratified by Pius on the 14th August 1801. Its value, however, from the pontifical point of view was considerably lessened by the "*Articles Organiques*" appended to it by the French Government on the 8th April 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months. He returned to Rome on the 16th May 1805 with many expressions of good will; but in the October following the French troops, in evacuating the kingdom of Naples, suddenly occupied Ancona upon the alleged necessity of protecting the Holy See. Resistance by force was out of the question, but to a requisition from the emperor that all Sardinians, English, Russians, and Swedes should be expelled from the pontifical states, and that vessels of all nations at war with France should be excluded from his ports, Pius replied by asserting the independence and neutrality of his realm. After negotiations had dragged on for two years, in the course of which the French occupied the chief Adriatic ports, Civita Vecchia was seized and the papal troops placed under French officers. On the 2d February 1808 Rome itself was occupied by General Miollis; a month later the provinces of Ancona, Macerata, Fermo, and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Vienna on May 17, 1809, the emperor declared the papal states reunited to France by resumption of the grant of Charlemagne. Pius retaliated by a bull, drawn up by Fontana and dated June 10, 1809, excommunicating the invaders; and, to prevent insurrection, Miollis—either on his own responsibility, as Napoleon afterwards asserted, or by order of the latter—employed General Radet to take possession of the pope's person. The palace on the Quirinal was broken open during the night of July 5th, and, on the persistent refusal of Pius to renounce his temporal authority, he was carried off, first to Grenoble, thence after an interval to Savona, and in June 1812 to Fontainebleau. There he was induced, on the 25th January 1813, to sign a new concordat, which was published as an imperial decree on the 13th February. On conference with the cardinals, however, Pius withdrew his concessions and proposed a concordat upon a new basis. At first no attention was paid to this, and, when after the French armies were driven from Germany Napoleon endeavoured to purchase a new concordat by offering to restore the papal possessions south of the Apennines, Pius refused to treat with him from any place other than Rome. The order for his departure thither reached him on the 22d January 1814, and after a brief delay at Cesena he entered Rome on the 24th May 1814. With his states restored to him by the congress of Vienna and freed from the Napoleonic terror, he devoted the remainder of his life to social and ecclesiastical reform in accordance with the modern spirit, suppressing many of the feudal survivals, abolishing torture, reconstituting civil and judicial procedure, and giving effect to many beneficial changes introduced by the French. His long and in many

respects admirable pontificate of more than twenty-three years' duration was brought to a close by an accident. His thigh having been broken by a fall in July 1823, acute inflammation supervened, and he died on the 20th August in that year. His successor was Leo XII.

PIUS VIII. (Francesco Xaviero Castiglioni), pope, was born at Cingoli near Ancona on November 20, 1761. After having been appointed bishop of Montalto in 1800, cardinal and bishop of Cesena in 1816, and bishop of Frascati in 1821, he was in 1829 declared successor of Leo XII. His unimportant pontificate was of little more than sufficient duration to enable him to give expression to convictions largely characterized by narrowness and intolerance in his choice of Cardinal Albani as head of affairs, and in his encyclical letter against the liberty of the press, civil marriage, and similar impious institutions. His death took place at Rome on the 30th November 1830. He was succeeded by Gregory XVI.

PIUS IX. (Giovanni Maria Mastai Ferretti), pope from 1846 to 1878, was born 13th May 1792 at Sinigaglia, near Ancona, the fourth son of Count Jerome and the Countess Catherine Vollazi of the same place. The family of Mastai is of ancient descent, and its representatives have frequently filled the office of mayor in Sinigaglia. The title of count was first given to its head by Prince Farnese, duke of Parma, towards the close of the 17th century. Somewhat later the elder branch, having become allied by marriage with the last representative of the family of Ferretti, assumed its second name. From the age of eleven to sixteen Giovanni received his education at the college of Piarists at Volterra, in Tuscany; a liability to epileptic fits precluded, however, much application to study. On one occasion, when thus attacked, he fell into a lake and was only saved from drowning by the intervention of a herdsman who observed the occurrence. A handsome lad, with a certain charm of expression and demeanour which characterized him throughout his life, he frequently attracted the attention of visitors to the college. On leaving Volterra, he conceived an attachment for a lady (afterwards a duchess), and the non-recital of his passion is said to have been a main cause of his resolution to enter the church. In 1818 he was invited to accompany Monsignor Odescalchi, a prelate attached to the pontifical court, on a visitation tour in his native province. On returning to Rome, he was encouraged by Pius VII. to persevere in his design of entering the church, was admitted (18th December 1818) to deacon's orders, and celebrated his first mass at the church of S. Maria del Falignani on Easter Sunday 1819. His benevolent disposition had led him about this time to interest himself in an orphanage, familiarly known by the name of "Tata Giovanni," and he was now appointed by Pius to preside over the establishment, and continued to fill the post for five years. In 1823 he accompanied the apostolic delegate, Monsignor Muzi, to the republic of Chili, and remained at Santiago for two years, actively engaged in missionary labours. In 1825 he returned to Rome, was made a canon of S. Maria in the Via Lata, and appointed to preside over the hospice of San Michele,—a vast charitable institution for destitute children. Here he remained somewhat less than two years, being promoted 21st May 1827, by Leo XII., to the archbishopric of Spoleto. His residence in that city was marked by many acts of benevolence, and especially by the foundation of a large orphanage where poor children were maintained and educated and also taught some mechanical art. Here, as at Rome, his genuine kindness and conciliatory disposition made him deservedly popular, but his defects were also not less apparent. He had allowed the hospice to become financially embarrassed, and after succeeding to the episcopal

office showed himself incapable of duly regulating his own expenditure.

During the insurrectionary movements which followed upon the election of Gregory XVI. to the papal chair, headed by Menotti and the two Napoleons—Charles Louis (afterwards emperor of the French) and his brother—Archbishop Mastai did his best to protect the insurgents. He disapproved of the reactionary policy of the new pope, and strongly resented the oppressive rule of the Austrians. When Napoleon (against whom sentence of death had been pronounced) fled to Spoleto, the archbishop, to whom he applied for help, obtained for him the services of an officer who conducted him beyond the frontier to a place of safety. In the following year (1832) he was translated to the bishopric of Imola, and a few years later was elected a cardinal, being reserved *in petto* in the consistory of 23d December 1839, and proclaimed cardinal 14th December 1840. It was not until overcome by the persuasion of others that Gregory XVI. consented to bestow this dignity on his future successor. He is said to have expressed his conviction that Mastai's liberal tendencies and impulsive disposition unfitted him for power, and that if he should ever become pope he would be the ruin of the church. During the tenure of his bishopric at Imola, Mastai gained additional reputation by the foundation of various philanthropic institutions and marked simplicity of life.

On the death of Gregory XVI., he repaired to Rome, and on the evening of 16th June 1846 was elected to the papal chair as Pius IX., having chosen this name out of respect for his predecessor in the see of Imola, Pius VII. His election, at the final scrutiny, proved to be unanimous, the cardinals Patrizzi and De Angelis throwing all their influence in his favour. On the following morning, when it was too late, the Austrian ambassador received instructions from his Government to veto the new pope's election.

Pius's first act in his new capacity was to proclaim a general amnesty for political offences, whereby thousands of unhappy beings who had dragged out weary years in prison or in exile, ignorant, many of them, even of the offences with which they were charged, were restored to society. With genuine catholicity of feeling he visited and relieved even the poor Jewish population in the city. He authorized the construction of railways, organized a civil guard, and considerably modified the restrictions on the press. In order to develop further reforms he instituted a commission largely composed of laymen; and in 1847 he brought forward his scheme of a *Consulta*, or council of state, designed to assist him in the general temporal government. But, notwithstanding these concessions, the supreme power remained in the hands of ecclesiastics, and no measure passed by the council could acquire validity until it had been examined and approved in a conclave of cardinals. Hence, although both MAZZINI (*q.v.*) and Garibaldi were among his avowed supporters, the liberal party were still far from satisfied. His policy was regarded, on the one hand, with extreme dissatisfaction by Austria, and on the 17th July 1847 that power sent a force of 1500 men into Ferrara, where she was entitled by the treaty of 1815 to maintain a garrison. To this direct menace Pius replied by counter demonstrations and an indignant protest, but hostilities were ultimately averted. His policy was viewed with not less dislike at the court of Naples, but by the rest of Italy and throughout Europe he was at this time regarded as the champion of the national rights of his countrymen. Such was the posture of affairs when the revolution in Paris (February 1848) fanned into flames the already smouldering elements of insurrection throughout Europe. The Austrians were driven out of Milan; a republic was proclaimed in Venice

(see ITALY, vol. xiii pp. 488-89); and a "free Italy" became the general cry. At first Pius, who felt but little sympathy with the views represented by the son of Philippe Égalité, seemed disposed to head the movement. He dismissed his state-secretary, Gizzi, an irresolute and timorous politician, and appointed Cardinal Ferretti in his place. On 14th March 1848 appeared the *Statuto Fondamentale*, a more complete scheme for the reorganization of the temporal government of the papal states. By this two deliberative assemblies were created,—the first, the high council, the members of which were to be nominated by the pope himself for life; the second, the council of deputies, to be elected by the people, and to be entrusted with the chief voice in all questions relating to taxation. Over both these bodies, however, the college of cardinals retained the supreme authority; without its consent no measure could acquire legal validity. Liberty of the press was promised, but the ecclesiastical censorship was to be retained. A new ministry was formed, which, with two exceptions (Antonelli and Morichini), was composed of laymen. But at this juncture Pius began to waver. Although he had hitherto shown no sympathy with the Jesuits, he endeavoured to protect them against the measures now brought forward with a view to their expulsion, and when his general, Durando, crossed the Po without his orders, and denounced the Austrians as "the enemies of the cross of Christ," he disowned, in an allocution (29th April), all intention of participating in an offensive war for the purpose of rectifying the boundaries of Italy, and at the same time disavowed all complicity in the schemes then in agitation for creating an Italian federal republic, with himself as the nominal head. This apparent desertion of the national cause, at a time when the public mind had been roused to the highest pitch of excitement by the course of events at other centres, created an irreparable breach between Pius and the people. His new chief minister, Mamiani, who wished to see him a constitutional monarch, advocated further concessions—the handing over of the political government to the new assemblies and a responsible ministry. But after the Austrian successes in the north and Radetsky's entry into Milan (5th August), Mamiani was dismissed, and his place was filled by Count Rossi, the French ambassador, a statesman of signal ability and intrepid character, but of conservative views. On the 15th November 1848, as Rossi was alighting at the steps of the house of assembly, he was assassinated in broad daylight. It was an ominous symptom of the prevailing temper of the capital that this atrocious act elicited no expression of disapproval in the assembly, and drew forth no marks of sympathy with the victim's family. Two days later a numerous mob, largely composed of disbanded soldiers, assembled in the square of the Quirinal, and proffered fresh demands, at the same time intimating their intention, if these were not conceded, of commencing a general massacre of the inmates, excepting only the pope himself. After his secretary, Palma, had been shot by a bullet, Pius, in order to avert further bloodshed, made the requisite concessions, and assented to the formation of a new ministry, while he himself was made a virtual prisoner. On the 24th November he effected his escape, with the connivance of the French Government, to Gaeta, disguised as a dependant of Count Spaur, the Bavarian minister. Thus terminated what has been described as "the first and only attempt of a pope to govern in a liberal spirit."

From Gaeta he published a formal protest against the violence to which he had been subjected, and whereby his latest enactments had been extorted from him, at the same time declaring all measures decreed in Rome during his absence null and void. Gioberti, the Sardinian

minister, endeavoured without success to gain his concurrence in a new scheme for the formation of an Italian federation of princes. In the following February it was resolved in a consistory of cardinals to appeal to the chief Catholic powers (France, Austria, Spain, and Naples) for their aid in bringing about the re-establishment of the temporal sovereignty. About the same time (3d February 1849), as if to mark his undisturbed sense of his spiritual supremacy, Pius himself addressed an encyclic to the superior Catholic clergy throughout the world, enjoining that on appointed days of the year the doctrine of the Immaculate Conception B.V.M. should be preached throughout their dioceses. The decisive defeat of the Sardinian forces at Novara by Radetsky (23d March 1849) encouraged the papal party now to demand that Pius should be reinstated at Rome without any conditions being attached to his restoration. This demand created a divergence of opinion among the above-named powers; eventually General Oudinot landed at Civita Vecchia with 10,000 French soldiers, and De Tocqueville, the French minister for foreign affairs, sought to induce Pius to resume his sovereignty on the basis of the *Statuto Fondamentale*. This he resolutely refused to do, and after the occupation of Rome by Oudinot's forces he was permitted to return (12th April 1850) unfettered by any condition whatever.

Pius returned an altered man in relation to his state policy, in which, in fact, he was from this time guided almost entirely by Antonelli. A certain profession of a design to reform abuses was indeed made, but the former ecclesiastical ascendancy in the government was re-established, while the pope entered into the closest relations with the Jesuit party. Notwithstanding his specious disclaimers of any desire to take revenge for the past, the *Documenti Officiali*, published in 1860, prove that little mercy was shown to those who were suspected of disaffection. As, however, the continuance of the French occupation relieved him from any anxiety with respect to the maintenance of order, Pius was enabled to devote his attention chiefly to the objects which undoubtedly lay nearest to his heart,—the more complete definition of Roman dogma and the enhancement of the prerogatives of his office. In this direction his views had never been characterized by any liberality, as is sufficiently shown by his encyclic of 9th November 1846, his letter to the archbishop of Cologne (3d July 1847), and his allocution of 17th December 1847, in which all the modern tendencies to a more philosophic interpretation of doctrine are visited with unqualified condemnation. He now proceeded skilfully to avail himself of the reaction that began to set in, especially in Germany and in England, after the repression of the revolutionary movements, by taking, as the burden of his allocutions, the essential connexion between political innovation and freedom of scientific or religious thought. The activity of the Jesuits was studiously encouraged; the "beatification" of several eminent deceased members of their order was proclaimed; and lives of the saints, full of marvellous and legendary incidents, were widely circulated among the poorer laity. A combination of circumstances, at this period, largely contributed to the success of these efforts both in Europe and in America. By the bull "Ineffabilis Deus" (8th December 1854) the doctrine of the immaculate conception was formally "defined," as a dogma binding on the acceptance of all the faithful, and in pamphlets favourable to the assumptions of the curia it was pointed out that the supreme pontiff had thus defined the doctrine *without recourse to any council*. In 1862 the canonization of six hundred and twenty missionaries, who had met with martyrdom in Japan some two centuries and a half before, was made the occasion of an imposing ceremonial. In a letter (11th December 1862) to

the archbishop of Munich, the teaching of Frohschammer, a distinguished professor of philosophy in the university in that city, was singled out for severe reprobation. The famous encyclic *Quanta cura*, and the *Syllabus*, or list of prevalent errors calling for especial reprobation, appeared in December 1864.

The war between France and Austria and the treaty of Villafranca (8th July 1859; see ITALY, vol. xiii. p. 490) seemed at one time likely to result in placing the temporal power on a basis somewhat resembling that indicated in Gioberti's pamphlet of 1843, and the ultramontane party waited with lively expectation the assembling of the congress. Among the inhabitants of the Romagna themselves, however, discontent with the political administration was intense. The papal rule had become almost as oppressive as that at Naples; and the prisons of Rome were filled with inmates against whom no more definite charge could be brought than that of suspected disaffection towards the Government. The manner in which the currency had been tampered with was alone sufficient to produce the gravest discontent, and the *lira papalina* was eventually accepted at the money-changers' only at a heavy loss to the holder. When, in the spring of 1857, Pius visited central Italy, it was observed that, while in other provinces he was greeted with enthusiasm as the pope, in his own dominions he was received with sullen coldness. A pamphlet published at Paris in December 1859 (ascribed to imperial inspiration), after describing the condition of the Romagna, openly raised the question of the continuance of the temporal power, and suggested that it would at least be desirable that it should be restricted to the capital itself. Pius replied in an encyclic issued on the 19th of the ensuing January—a document since widely known as his *Non Possumus*. His obstinacy proved of no avail. The Romagna was occupied by Sardinia, and the Central-Italian states shortly afterwards formed themselves into a league to prevent its reoccupation by the pontifical forces. Antonelli rejoined by raising a motley force, composed of French, Belgians, Bavarians, and Irish, who were placed under the command of Lamoricière, an able French officer who had seen active service in Algiers. There can be no doubt that, in making this apparently hopeless effort, the curia was deluded by the belief that, if matters proceeded to extremities, France would intervene in its behalf. After a stubborn resistance at Ancona, the superior forces of Sardinia prevailed, and in September 1860 the whole of the States of the Church, with the exception of the *patrimonium Petri* (see POFEDOM), were annexed to the kingdom of Victor Emmanuel.

From the reduction of Ancona to the year 1870 Pius was maintained in Rome only by a French garrison. The emperor of the French was reluctant to appear altogether to desert the papal cause, while Cavour was unwilling, in like manner, to proceed to extremities. After the capture of Garibaldi at Aspromonte, however, Victor Emmanuel felt himself strong enough to put in a formal claim for Rome; and it was eventually arranged, by the convention of 15th September 1864, that the French should withdraw from the city before the end of 1866. This stipulation was duly observed, and on the 11th December 1866 the last of the French forces quitted the capital. The engagement was, however, virtually violated by the entry, in the following year, of the Antibes legion, and for some time longer the French soldiery continued to ward off both the daring assaults of Garibaldi and the more insidious approaches of Ratazzi. In this manner, at the outbreak of the war of 1870, France had come again to be looked upon as the ally of the papacy; and the overweening claims put forward by Pius in convening a general council to proclaim the dogma of Papal Infallibility were generally

interpreted as in a certain sense correlative with the aggressive designs of France on Protestant Germany. The dogma was decreed in the Vatican on the 18th July, but not without strenuous opposition on the part of some of the most distinguished members of the Catholic episcopal order, who, at the same time, were staunch supporters of the temporal power (see OLD CATHOLICS). At nearly the same time the occupation by the French came definitively to an end. Their forces were withdrawn from Civita Vecchia at the outbreak of the war, when the Duc de Gramont announced that his Government relied on the convention of 1864, whereby Italy was bound not to attack the papal territory. That territory being now, however, again exposed to the dangers of revolution, Victor Emmanuel, on receiving the tidings of the battle of Gravelotte, notified to Pius that "the responsibility of maintaining order in the peninsula and the security of the Holy See" had devolved upon himself, and that his army must enter the pontifical dominions. This intimation was received by Pius with demonstrations of the liveliest indignation, but the appearance of the Sardinian troops was hailed by his own subjects with enthusiasm. On arriving outside Rome, General Cadorna summoned the garrison to surrender, and after a short bombardment the white flag was hoisted. On the following day (21st September 1870) the Zouaves, some nine thousand in number, after receiving, as they stood massed in the square of St Peter's, the pontifical blessing, marched out of Rome, and the temporal power of the pope had ceased to exist.

For the rest of his days Pius IX. remained unmolested at the Vatican, while the king resided at the Quirinal. The pontiff was virtually a prisoner; and his position, although viewed with comparative indifference in Rome, was regarded with not a little sympathy by the Catholic world at large. The tribute of Peter's Pence was revived in order to supply, in some measure, the loss of his alienated revenues; and numerous pilgrimages, in which distinguished and wealthy individuals took part, were made to St Peter's from all parts of Catholic Christendom, and especially from England. His advanced years, fine presence, dignified demeanour, and elasticity of spirits (unbroken by his adverse fortunes) combined to invest both the person and the office of the pope with a kind of fascination for devout minds, which those about him well understood how to turn to the best advantage. Occasionally, however, his naturally impetuous temper still manifested itself. The complicity of the Roman Catholic clergy with the Polish insurrection of 1863 had been punished by Russia with excessive rigour, and, on receiving the Russian deputies who came to offer the customary felicitations on New Year's Day 1866, Pius so far forgot the proprieties of the occasion as to himself address them in terms of reproach. A suspension of diplomatic relations ensued; and Russia now eagerly availed herself of the pretext afforded by the promulgation of the new dogmas to aim a severe blow at Roman Catholic influence within her dominions, by annexing to the Russian Church the bishopric of Chelm, with a population of over 300,000 souls. Pius showed his resentment by espousing the side of Turkey in the struggle of that country with the Russian power. On the 3d June 1877 he celebrated the fiftieth anniversary of his consecration to the archbishopric of Spoleto, and the event was made singularly memorable by the spectacle of numerous deputations, bearing costly offerings, from all parts of the world. Pius died on the 8th of the following February, and was succeeded by Cardinal Pecchi as Leo XIII.

The life of Pius has been written by the late J. F. Maguire (2d ed., 1878), and by Leopold Wappmannsperger, *Leben und Wirken des Papstes Pius des Neunten* (Ratisbon, 1878). Both

authors write from the ultramontane point of view, but the latter much more in detail, giving original documents and information respecting events subsequent to 1870 not to be found in English sources. Nippold's *Handbuch der neuesten Kirchengeschichte*, vol. ii., supplies an outline of the papal policy in connexion with other contemporaneous religious movements; and a concise but more impartial sketch will be found in Ranke, *Die römischen Päpste* (7th ed.), ii. 162-203. The literature connected with the Vatican Council is given under OLD CATHOLICS. (J. B. M.)

PIZARRO, FRANCISCO (c. 1471-1541), discoverer of Peru, and the principal hero of its conquest, born at Truxillo in Estremadura, Spain, about the year 1471, was an illegitimate son of Gonzalo Pizarro, who as colonel of infantry afterwards served in Italy under Gonzalvo de Cordova, and in Navarre, with some distinction. Of Pizarro's early years hardly anything is known; but he appears to have been only poorly cared for, and his education was certainly neglected. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence found his way across the Atlantic; there he is first heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá under Alonzo de Ojeda, by whom, in his absence, he was entrusted with the charge of the unfortunate settlement at San Sebastian. Afterwards he accompanied Balboa to Darien; and under Balboa's successor, Pedrarias, he received a "repartimento," and became a cattle farmer at Panama, where in 1522 he entered into a partnership with a priest named Hernando de Luque and a soldier named Diego de Almagro for purposes of exploration and conquest towards the south. An expedition along the coast of New Granada (November 1524) was unfortunate, but supplied various confirmations of rumours previously heard as to the existence of a great and opulent empire farther to the south. On March 10, 1526, Pizarro, Almagro, and Luque renewed their compact, but in a much more solemn and explicit manner, to conquer and divide equally among themselves this empire still undiscovered, and Pizarro and Almagro, with a force of about one hundred and sixty men, again sailed from Panama. The force was too small to effect much at the time, and was at length recalled by the governor, but Pizarro was not to be shaken, and, though he was left for months with but thirteen followers on a small island without ship or stores, persisted in his enterprise till at length he had coasted as far as to about 9° S. lat., and obtained distinct accounts of the Peruvian empire. The governor still showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain in the spring of 1528, reaching Seville in early summer. After long and tedious delays, the queen, in Charles's absence, executed at Toledo on 26th July 1529 the famous *capitulacion* by which Pizarro was upon certain conditions made governor and captain-general of the province of "New Castile" for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy. One of the conditions of the grant was that within six months he should raise a sufficiently equipped force of two hundred and fifty men, of whom one hundred might be drawn from the colonies; but this he had some difficulty in fulfilling. Sailing from San Lucar clandestinely (for his due complement was not yet made up) in January 1530, Pizarro was afterwards joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, one hundred and eighty men, and twenty-seven horses. A footing was established on the mainland at Tumbes, whence Pizarro set out for the interior in May 1532. San Miguel de Piura was founded a few weeks afterwards, and Caxamarca entered on November 15th. The subsequent movements

of Pizarro belong to the history of PERU (see vol. xviii. p. 677; and, for authorities, comp. p. 679).

PLAGUE (λαμὸς, *Pestis*, *Pestilentia*). This name has been given to any epidemic disease causing a great mortality, and in this sense was used by Galen and the ancient medical writers, but is now confined to a special disease, otherwise called Oriental, Levantine, or Bubonic Plague, which may be shortly defined as a specific febrile disease, transmissible from the sick to healthy persons, accompanied usually by buboes and sometimes by carbuncles. This definition excludes many of the celebrated pestilences recorded in history,—such as the plague of Athens, described by Thucydides; that not less celebrated one which occurred in the reign of Marcus Aurelius and spread over nearly the whole of the Roman world (164-180 A.D.),<sup>1</sup> which is referred to, though not fully described, by the contemporary pen of Galen; and that of the 3d century (about 253), the symptoms of which are known from the allusions of St Cyprian (*Sermo de Mortalitate*). There is a certain resemblance between all these, but they were very different from Oriental plague.

*Symptoms*.—There are two chief forms:—(1) mild plague, *pestis minor*, larval plague (Radcliffe), *peste fruste*, in which the special symptoms are accompanied by little fever or general disturbance; and (2) ordinary epidemic or severe plague, *pestis major*, in which the general disturbance is very severe. Cases which are rapidly fatal from the general disturbance without marked local symptoms have been distinguished as fulminant plague (*pestis siderans*, *peste foudroyante*).

1. In the minor form of the disease spontaneous swellings of the glands occur, chiefly in groins and armpits, but also in neck or other parts, which either undergo resolution or suppurate. There is a certain amount of fever; the temperature is rarely high, but has been known to be 104° Fahr. The duration of the disease is ten to twenty days usually, but may be eight weeks, for most of which time the general health is little impaired and the patient able to go about as usual. It rarely, if ever, causes death, the only fatal case at Astrakhan in 1877 having been so through a complication. The disease is not obviously contagious; whether it is propagated by infection or not is unknown. It is possibly rather of a miasmatic character. This form of disease has sometimes preceded or followed severe epidemics, as in Mesopotamia (Iraq) on several occasions, 1873-78, and in Astrakhan, 1877; its importance in relation to the origin of plague has only lately been appreciated.<sup>2</sup>

It might be expected that gradations would be found connecting this form with the severe epidemic form; but this appears to be not usually the case, the latter form appearing somewhat suddenly and abruptly. Hence the minor form has probably often been regarded as a distinct disease, even when observed in plague countries.

2. As regards *pestis major*, or severe plague, the symptoms appear to have been nearly the same in all great epidemics for several centuries, if not for two thousand years, but will be best given from modern observations, such as those of Surgeon-Major Colvill, Dr Cabiadis, and others in Iraq, and recent observers in India. The early symptoms are sometimes like those of ague (shivers, often long continued, and pains in the limbs), but combined with nervous symptoms. The patient becomes distracted, tosses about in constant fear of something he cannot describe,

<sup>1</sup> Amm. Marcell., xliii. 7; see Hecker, *De Peste Antoniana*, Berlin, 1835.

<sup>2</sup> Payne, *Trans. Epidem. Soc. of Lond.*, iv. 362; Tholozan, *La Peste en Turquie*, Paris, 1880; J. N. Radcliffe, *Report of Local Government Board*, 1879-80 (Supplement, pp. 24, 49), and article "Plague," in Quain's *Dictionary of Medicine*, London, 1882.

has a difficulty in understanding the questions put to him, and is slow in answering. He is often described as staggering like a drunken man. There is severe headache, intense thirst, and severe pain in the epigastrium. The eyes are red and turbid; the tongue swollen, dry, and fissured, sometimes black, sometimes remarkably white (Colvill). This condition may pass into coma even before fever sets in. In other cases bilious vomiting is the earliest symptom. The fever which sets in may last twenty-four to thirty hours, or more. The temperature may be 100° to 107° Fahr., or even higher; but in the most rapidly fatal cases there may be little or no fever. Generally there is obstinate constipation, but sometimes diarrhoea. Besides these symptoms there are certain special ones especially characteristic of plague.

(a) Buboes or glandular swellings are observed in all except very rapidly fatal cases. They occur in 45 or 50 per cent. of the cases in the groin, in 35 per cent. in the axilla, also less frequently in the neck or other parts. These swellings may occur before the fever, simultaneously with it, or some hours after it has set in. A sudden pain like that of a stab is felt in some region of the body, which has given rise to the superstition that the unfortunate victim was wounded by the arrow of an invisible demon,—a belief recorded in Constantinople in the 6th century, and said still to survive in Mohammedan countries. The buboes may suppurate, and free discharge of matter from them has in all times been held to be a favourable sign and conducive to recovery.

(b) Carbuncles were observed in about 2½ or 3 per cent. of the cases in recent epidemics in Irak. They are always an unfavourable sign.

(c) Petechiæ or hæmorrhagic spots on the skin have always been regarded as signs of the worst omen. Under the name of "tokens" they were considered in the English epidemics of the 16th century as the infallible signs of approaching death. "They appear generally only a few hours before death" (Colvill). Hodges (1665) noticed hardness which showed the existence of hæmorrhage under the skin. The skin is sometimes so covered with petechiæ as to become of a dark livid hue after death, recalling the name Black Death (Cabiadis).

The occurrence of the above symptoms, especially the first, in an idiopathic fever attacking many persons at one time is sufficient to make the diagnosis of plague.

A very notable and fatal form of the disease is that in which hæmorrhages from the lungs, stomach, bowels, nose, &c., occur. These are of the worst omen, and are seen in some cases where there are no buboes, and which are rapidly fatal. This was observed in Irak in recent epidemics, in the outbreak on the Volga in 1878-79, and in the plague of India. It was a noticeable symptom in the black death, and was observed even in the plague of the 6th century. The bleeding is mostly from the lungs, and is sometimes associated with other symptoms of lung affection. This form of the disease appears, however, to have no distinct historical or geographical limit. A similar hæmorrhagic form has been observed in small-pox and scarlet fever, and is always extremely fatal.

In all plague epidemics cases occur in which death takes place very rapidly, even within twenty-four hours, without the development of the special symptoms of the disease. Such cases are reported by Diemerbroek, Hodges, and others in the 17th century, and have been observed in recent epidemics in Irak, as well as in the recent plague on the Volga. Some are more like cases of poisoning than of infection, and much resemble the instances of death from the exhalations of dead bodies (cadaveric poisoning) which are met with from time to time. It is these which have given rise to the expression fulminant plague.

*Duration.*—The duration of an attack of plague may be from some hours to a month. Three-fifths of the cases observed by Mr Colvill were fatal on the third day, and the majority of cases in India had the same termination (Francis). Five-sixths of fatal cases end by the fifth day. Most of those who survive the fifth day get well; after the seventh day a patient in Baghdad was considered by his friends safe; and in Mr Colvill's cases only 4 per cent. of fatal cases died after the tenth day. In non-fatal cases with suppurating buboes the disease may be protracted to two or three weeks or a month.

*Mortality.*—Plague is the most fatal of all known diseases which affect large numbers of people. The mortality, according to official registers in Baghdad, was 55·7 per cent. of those attacked. Dr Cabiadis thinks this too high, owing to many cases of recovery not being reported. But in some epidemics the proportion of fatal cases is much higher. In Vetlanka it was about 90 per cent., and in some other villages on the Volga every person who took the disease died. The older accounts do not give the proportion of deaths and attacks.

*Morbid Anatomy.*—Examinations after death have not done much to elucidate the nature of plague, except negatively. The appearances are those of death from an acute infective disease, and resemble those of typhus, except for the special affection of the lymphatic glands. The brain and the lungs are found to contain excess of blood; the right side of the heart distended, the blood dark-coloured and undergoing rapid decomposition.<sup>1</sup> The spleen is found enlarged, and in a less degree the liver. The stomach and intestinal canal often show signs of inflammation and hæmorrhage, sometimes ulceration. The characteristic swelling of the lymphatic glands, both external and internal, is often accompanied by inflammation of the cellular tissue around. Petechial patches are sometimes found on the internal organs.<sup>2</sup>

*Pathology of Plague.*—All that is known of plague goes to show that it is a specific febrile disease depending on the reception into the body of a specific organic contagion, which becomes multiplied in the body of the patient. Analogy makes it very probable that this contagion is a living organism of the class *Bacteria*, but the suspected organism has not yet been discovered. The nearest ally of plague is typhus fever, so that some authorities have spoken of it as the typhus of hot climates, modified by temperature, &c., but this opinion does not appear to have ever been held by any competent physician who has examined the disease at first hand. It appears to be as distinct from typhus as this is from enteric fever, or other so-called typhoid diseases. It has also been thought that plague is related to intermittent or remittent malarious fevers; but the most recent observations show that there is no real connexion between these diseases. In India, says Dr Francis, neither intermission nor remission has ever been observed in plague. It is quite distinct from and in no way modified by the types of fever that are caused by malaria. Dr Cabiadis speaks to the same effect of plague in Irak, and insists that the physical conditions which favour the production of marsh poison are not necessarily favourable to plague.

*External Conditions of Plague.*—The nature of the soil

<sup>1</sup> This post-mortem decomposition of the blood is doubtless the cause of some appearances described with great particularity in the older accounts.

<sup>2</sup> Our knowledge of the morbid anatomy of plague is derived almost entirely from the observation of the French physicians in Egypt during the epidemic in 1835-36. Earlier observations are of no value, and in later epidemics of Irak and Russia none have been made. In India Drs Pearson and Francis made a few autopsies. Clot-Bey, *De la Peste en Égypte*, Paris, 1840; Bulard, *De la Peste Orientale*, Paris, 1839; Francis, *Indian Annals of Medical Science*, vol. i., 1854.

has little influence on plague. It may flourish in alluvial deltas, on calcareous ridges or granitic mountains. Moisture in the soil has generally been thought to be an important factor in its production, but, though often found in marsh situations, such as the banks of the Nile, the Euphrates, or even the Volga, it also occurs in India at elevations approaching 7000 feet, and in Kurdistan at 5000 to 6000 feet above the sea.

The temperature most favourable to plague is a moderately high one. The disease is unknown in the tropics. When prevalent in Egypt it was said never to penetrate farther south than Assouan. It has not crossed the plains of India within historic times. Where the disease does occur, a temperature of 80° to 85° or more, combined with absence of moisture, usually stops the epidemic. In Egypt it was observed to cease as an epidemic almost suddenly about the 22d to 24th of June, and not to begin again till September. In Irak it dies out suddenly during the summer. When the temperature rises above 86° it begins to diminish; and it ceases abruptly at a temperature of 113°. In India it has been observed by Dr Francis when the temperature of his tent was 83° to 95°, or in a grass hut to 105°, while the air was moist; but he thinks a lower temperature with dryness renders the poison inert.

On the other hand, in northern countries, the disease is usually checked by the cold of winter, starts up in the spring, and is most active in August and September. To this rule there have been some remarkable exceptions, such as the epidemic on the Volga in 1878-79, which raged during severe winter weather, and the great plague of Moscow in 1770.

*Sanitary Conditions.*—Of all the co-operating causes of the plague, *uncleanliness* is the most powerful,—meaning by this the accumulation of decaying animal matter around human bodies or dwellings. The saturation of the soil with filth is perhaps the most important point. A plague seat in Mesopotamia is thus described by Colvill:—"The ground is so saturated with moisture that the refuse of the village is neither absorbed nor evaporated, but . . . acquires the form of a bluish-black oily fluid, which surrounds the huts and covers the paths, and stains the walls 2 feet from the ground; and in fact the village is in such a state of filth that it requires to be seen to be believed." Of the people among whom the Pali plague of India raged it is said "they were filthy beyond conception" (Francis). There can be little doubt that European cities in the Middle Ages, and down to the 17th century, presented very similar conditions. These conditions may be considered to act by supplying a suitable environment for the life and growth of the organized poison (or bacterium) outside the human body. Where these are wanting one of the main factors in the spread and permanence of the disease will be absent, a fact which makes it probable that increased cleanliness is the chief cause of the disappearance of plague from Europe.

Overcrowded dwellings, especially with deficient ventilation, greatly favour the spread of the disease; but this is not necessarily correlative with density of population, and plague may flourish in thinly-peopled countries.

Of social conditions *poverty* has by far the most powerful influence on the spread and development of plague. Many plague epidemics have followed on years of famine, or been connected with destruction of crops and cattle. The races among which the disease is endemic are almost without exception under-nourished, if not destitute. In the villages on the Volga there appeared to the writer, in 1879, to be little destitution, though the diet of the people was very meagre. In all city epidemics the poor are the chief or almost the only sufferers. This is as true of Baghdad in the 19th century as it was of London in the

17th. Those of the upper classes who have been attacked have been chiefly doctors, clergy, officials, and others whose occupations take them among the sick.

*Origin and Spread of Plague.*—Although the above-mentioned conditions are those in which plague originates, and may be considered in a general way essential to its continued existence, it is plain that they do not account for its origin. Poverty, overcrowding, filth, and marsh soil, with a temperature suited to plague, occur in many parts of the world where this disease has never been heard of or has ceased to exist. The geographical distribution of diseases cannot, any more than the distribution of plants or animals, be explained by climatic causes alone. With regard to plague it is quite clear that there are some parts of the world where it is at home, or, as the phrase is, "endemic." In other parts it is probable (or, as some think, certain) that its existence, and even its periodical recurrence, depend on importation from an endemic centre. Although it is not always easy to distinguish between these cases, they must be considered separately.

In the case of an endemic disease we suppose that the poison is either kept in existence by continued transmission from one case to another, or that it can subsist outside the human body in soil, water, or otherwise. The first mode of existence is that of a pure contagious disease, such as small-pox; and it is plain that this mode of continued existence obtains in the case of plague also. It is not, however, clear that the second may not also be one of the modes of existence of plague, which would then be a so-called "miasmatic" disease like ague, as well as a contagious one. In India, for instance, the disease appears as if it depended on a poison in the soil, since it returns years after to the same spot, appearing in many villages simultaneously; and some morbid influence causes the death of animals (rats) which live under ground. Similar facts have been observed in China; and, if further inquiry should confirm the hypothesis, it would show that plague is (like anthrax or the "steppe murrain" of cattle) both miasmatic and contagious. If so, there is no difficulty in supposing the disease to be carried by contagion to a distant part, and there to be established in the soil, for a longer or shorter period, as the conditions are more or less favourable. The adoption of this hypothesis would remove many of the difficulties attending the explanation of plague epidemics, and to some extent reconcile the controversies of the last three centuries between the "contagionist" and "non-contagionist" schools. It has been maintained by the former that European epidemics have always been caused by the importation of the disease from its home in the East, by the latter that it arose on European soil in the same way as in Egypt or Syria.

In the case of an imported non-endemic disease, the only question which arises is how the importation is effected,—whether the disease may be brought by the air alone, whether by infected persons only, or whether also by objects which have been in close relation to infected persons. Transmission of the disease by the air cannot be pronounced impossible; and there are facts to show that it is even probable with distances measured by yards, or possibly even hundreds of yards; but there is no evidence whatever that the disease has ever been carried by the air over distances measured by miles. Transmission of the disease by infected persons over longer or shorter distances, and from one country to another, is an established fact. Transmission by infected objects over great distances and from one country to another seems less clearly established. The last two cases must be separately considered.

1. It is clear that the first necessary condition to such transmission is *contagion*, or transference of the disease from the sick to the healthy. The existence of contagion

is shown by such facts as these:—when a case of plague breaks out in a house the other inmates are extremely likely to take the disease; and even in severe forms the plague does not cease till it has affected all or nearly all the household. This is indisputably an almost universal law. In the plague of London in 1603 it was said the disease entered hardly any house but it seized all that lived in it. And in 1879, on the Volga, in one village, as was ascertained by Mr Colvill and the present writer, the plague attacked five houses containing thirty-three persons, all of whom except two took the disease and died. In this respect plague resembles typhus. In the next place the disease will spread from an infected house to persons who have close relations with it. Thus in the villages on the Volga it was noticed that after one family was affected cousins and relations by marriage were the next to be attacked. Doctors and those visiting the house are also exposed to the risk, though in a less degree. In Vetlanka on the Volga three physicians and six surgical assistants died. On the other hand, doctors in some instances have singularly escaped from being attacked by the disease. In Egypt, in 1835, out of ten French physicians engaged one only died, nor was this immunity secured by any precautions. These experiences do not prove that the disease is not contagious, but they modify the exaggerated notions which have been held on the subject. The facts appear to be expressed by saying that it may undoubtedly be communicated from one person to another, but chiefly by breathing the air of the sick room, and this generally from prolonged not from momentary exposure,—so that the possibility of communication by chance meetings and similar contingencies may be disregarded. This view is that of Dr Cabiadis and others who have studied plague in Irak where no doctor or assistant, with one exception, suffered from the disease. It is not inconsistent with the experience recorded in Egypt. But it is clear that the intensity of contagion varies greatly in different epidemics. Modern experience contradicts the belief formerly entertained that contact with plague patients was the only or even the chief means of acquiring the disease. Everything tends to show that the atmosphere immediately surrounding the patient is the most effectual conveyer of contagion, and more effectual in proportion as the poison is concentrated. Precisely the same relations are observed with regard to typhus.

It has been disputed whether dead bodies convey infection of plague. Formerly the contagion from this source was greatly dreaded, and the task of burying thought to be specially dangerous. But the French in Egypt made more than a hundred post-mortem examinations without precautions and without harm. In Mesopotamia and in Russia no autopsies were made, but in the latter country some striking instances were noted of those engaged in burying the dead themselves dying of the plague. On the whole both facts and analogy lead to the belief that the disease may be derived from touching or being near a dead body, but not that there is any special danger of infection from this source.

2. It is a very momentous question whether the contagion is capable of being conveyed by clothes and other objects which have been in contact with the sick. The very general belief that this is so has been controverted only by the French physicians in Egypt, one of whom, Bulard, himself wore a shirt, taken direct from the body of a plague patient, for two days. They also state that in Egypt it was customary, when a plague epidemic was over, to sell the clothes and effects of those who had died of plague, without, as is affirmed, communicating the disease. In Constantinople they were customarily sold at once; and it is alleged that the dealers in old clothes did

not specially suffer. In 1835 the hospital at Cairo, where 3000 plague patients had been treated, was used, without even changing the bed coverings, immediately after the epidemic for other patients, without harm. Negative instances of this kind might be multiplied, but their importance is diminished by the consideration that the communicability of plague, by whatever means, is always found to become spontaneously weak at the decline of the epidemic, till it is extinct altogether. While the epidemic influence lasts there is abundant evidence that infected clothes, &c., are among the means by which the disease spreads. In Egypt, in 1835, two criminals condemned to death were for the sake of experiment placed in the clothes and beds of those who had died of plague, and both took the disease, one dying. Instances are given by White (*Treatise on the Plague*, p. 161, London, 1847) of the disease spreading "like wildfire" through the distribution of infected garments, and of those engaged in disinfecting clothes and other objects being suddenly seized with the complaint, *e.g.*, on opening a box containing infected garments. While the reality of this mode of communication cannot reasonably be doubted, it admits of some question whether the plague has ever been thus conveyed over great distances, or from one country to another. The best known instance in England is the alleged transmission of plague from London to the village of Eyam in Derbyshire in 1665 by an infected parcel of clothes,—a story which cannot be criticized at this distance of time, but which presents some weak points.<sup>1</sup> Dr Cabiadis states that he has seen plague thus conveyed in Irak to places outside the existing focus of infection, but gives no details. On the whole we must consider the exportation of plague by clothes over great distances, and into countries not subject to the same epidemic conditions as the infected country, "not proven."

The communication of plague by merchandise or objects not personal, coming from an infected country, rests upon still more defective evidence, though at one time generally believed. In virtue of this belief all goods, especially those regarded as susceptible (as wool, furs, raw cotton, &c.), were, when coming from an infected or suspected country, subjected to disinfection under special regulations. But there is really no evidence that plague was ever thus transmitted or that these regulations kept it out. On the contrary there are numberless instances of this supposed cause having failed to operate when it might have been most expected to do so.

During the plague at Alexandria in 1835, which destroyed 9000 persons in that city, the exportation of cotton from the Government warehouses was never interrupted, though the plague was most destructive in those very buildings. It was loaded on English and other ships without any precautions whatever. Twenty-five ships, eight of which were infected with plague, conveyed cotton amounting to 31,000 bales to England. Nevertheless no case of plague is known to have occurred among the quarantine officers or others engaged in unloading these ships or disinfecting their cargoes in quarantine. Equally large quantities were exported to Marseilles and Trieste, and smaller quantities to other ports, with the same result. Further, no case of infection has occurred among quarantine officers or persons employed to disinfect goods, from this cause alone, either at Marseilles since 1720, or at any European lazaretto.<sup>2</sup> The conclusion is that the fear of importation of plague by merchandise coming from an infected country rests on no solid foundation.

By whatever means, there is no doubt that plague is

<sup>1</sup> See W. Wood, *History of Eyam*, London, 1848.

<sup>2</sup> Laidlaw, quoted in Prus, *Rapport*, p. 479.

diffused or "spreads" from one place to another, and that its spread is connected mediately or immediately, in most cases at least, with human intercourse. But this diffusion appears to take place as a rule slowly, and to be effected by the formation of new foci of contaminated atmosphere. Such foci on land will be inhabited houses, and the disease will creep in a gradual though irregular manner from house to house and street to street. It was so in London in 1665; and in Russia in 1878, as has been said, the disease was confined to one village for two months, though for great part of the time communication was perfectly open. In 1834 plague existed eight months at Alexandria before passing to Damietta and Mansoorah, though traffic was quite uninterrupted. These new foci of disease are doubtless mostly produced by persons infected with the disease, actually or in incubation, who form a contaminated atmosphere around them in a place previously healthy.

Transmission of the disease by sea may take place in the same manner,—a ship forming a focus of disease as easily as a house, and being obviously specially liable to concentrate the poison. It is by a floating atmosphere of plague, and not by casual contaminated objects, that the disease has been conveyed, when it has been, from one port to another of the Mediterranean. The reality of the mode of transmission is shown by the fact that between 1720 and 1845 twenty-five ships arrived at French and Italian ports with the plague among their crews; and in the case of those arriving at Marseilles (ten in number), which were carefully observed, there were several instances of plague being communicated in the lazaretto to surgeons and others, or to those placed in charge of the ships. Of these persons several died,—without, however, any extension of the disease to the town. From this it is clear that plague may be transmitted by ships, and may spread at the point to which it is conveyed, if the surrounding circumstances are favourable. In all these cases the ships had left the infected ports at a time when an epidemic of plague, and not merely sporadic cases, prevailed there. No similar facts are on record as to the importation of plague by ships to England,—the probable cause of this difference being the greater length of the voyage from the Levantine ports, and the precautions taken at those ports to prevent the shipment of infected persons or goods. Plague has never been brought to an English quarantine station.<sup>1</sup>

In such cases it must remain undetermined whether the disease would have spread, had it not been interrupted by the quarantine. As we have seen, plague will often die out in the cases which convey it without spreading; and hence some have supposed (with Sydenham) that an "epidemic constitution" is necessary at any particular time and place in order that the disease should become general, but the practical value of this law is diminished by the fact that there is no means of recognizing the epidemic constitution except by the actual production of an epidemic.

Plague, like all similar diseases, and in a specially high degree, is subject to the law of periodicity. Even when it is most strictly endemic it seldom prevails continuously, but appears in definite outbreaks, or epidemics, with intervals in which there are either no cases of plague or only so-called sporadic cases. This may be partly due to the general law that the susceptibility of the population to a special disease is exhausted by an epidemic, partly to the immensely increased transmissibility of the disease caused by the increased number of cases, so that when once a certain stage of severity has been reached the disease progresses in a far more rapid ratio. In most epidemics of plague there is at one time a sudden and alarming increase

in mortality; but, by a law not yet understood, each epidemic is liable to a spontaneous decline, which is sometimes sudden. This may be connected with rise or fall in the temperature of the air, but is not always so. The disease may be dormant during the cold or hot weather (as the case may be) and reappear when the temperature is favourable again, but not necessarily. It is generally agreed that plague is transmissible to another country only when it is epidemic, and not from sporadic cases.

*Incubation.*—It is a very important question what time may elapse between a person receiving the poison and showing symptoms of the disease. The usual time of incubation appears to be from three to five days. In certain very malignant epidemics this period may be shortened, and, it is thought, reduced to even less than a day. In rare cases incubation may be prolonged to eight days. There are doubtful accounts of ten days' incubation. Generally a week's observation<sup>2</sup> would show whether a suspected person was really affected or no. It has been thought that articles contaminated by contact with plague patients may retain the power of communicating the disease for weeks, months, or even years; but of this there is no adequate proof.

*Treatment.*—No special line of treatment has proved efficacious in checking the disease once established. Special symptoms are treated in accordance with the ordinary rules of practice, and need not here be considered. Free ventilation appears to be of the greatest service in preventing the spread of the disease, and probably in promoting recovery.

*Prevention.*—There can be no doubt whatever of the efficacy of hygienic measures in rendering a locality unsuitable for the spread of plague. Such measures include, not only personal cleanliness, but especially the removal of all foul organic matters, good drainage, and prevention of overcrowding; all such measures might be looked upon by our readers generally as matters of course, but are quite unknown in most of the homes of plague. Since there is no doubt that plague may be carried from places where it prevails epidemically, measures to prevent such importation cannot be neglected. The best known of such measures is the system of quarantine first produced about 1480. See QUARANTINE. The efficiency of quarantine has been much discussed, and very strong opinions have been expressed for and against it. The subject is too large for discussion here; but it would appear that, while the system as originally applied in the Mediterranean, when traffic was comparatively slow and infrequent, and when European cities presented an extremely favourable soil for plague if introduced, was a real protection, the regulations have long ceased to correspond to the actual state of medical knowledge; and, in addition, it would be impossible to apply them to our crowded traffic. The alternative is a system of medical inspection of all arrivals in our ports, and strict isolation of ships in which plague has occurred or is suspected. Such a ship should then be treated as an infected house.

*Prevention of the Spread of Plague.*—When cases of plague have once occurred in a town or on board a ship in port, the house or ship should be emptied of its inhabitants, the sick removed to a hospital, the sound placed in an isolated building and subjected to observation for at least a week, or, better, ten days. The clothes of sick persons had better be burnt, their bedding and furniture completely disinfected. The house should in the meantime be rigidly closed until it has been disinfected. If these measures are taken in time, there can be no objection to allowing free emigration of the population. Isolation of the place by a "sanitary cordon" would only be possible

<sup>2</sup> Prus, *Rapport*, p. 196.

in very exceptional positions, and as a rule would aggravate, by overcrowding, the intensity of the disease within.

*History of the Plague.*—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the *Collections of Oribasius*.<sup>1</sup> Rufus speaks of the buboes called pestilential as being specially fatal, and as being found chiefly in Libya, Egypt, and Syria. He refers to the testimony of a physician Dionysius, who lived probably in the 3d century B.C. or earlier, and to Dioscorides and Pedanius, who fully described these buboes in a work on the plague which prevailed in Libya in their time. Whatever the precise date of these physicians may have been, this passage shows the antiquity of the plague in northern Africa, which for centuries was considered as its home. The great plague referred to by Livy (11, Epitome), and more fully by Orosius (*Histor.*, iv. 11) was probably the same, though the symptoms are not recorded. It is reported to have destroyed a million of persons in Africa, but is not stated to have passed into Europe.

It is not till the 6th century of our era, in the reign of Justinian, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, accompanied by extraordinary natural phenomena, which lasted fifty years, and is described with a singular misunderstanding of medical terms by Gibbon in his forty-third chapter. The descriptions of the contemporary writers Procopius, Evagrius, and Gregory of Tours are quite unmistakable.<sup>2</sup> The plague of Justinian began at Pelusium in Egypt in 542 A.D.; it spread over Egypt, and in the same or the next year passed to Constantinople, where it carried off 10,000 persons in one day, with all the symptoms of bubonic plague. It appeared in Gaul in 546, where it is described by Gregory of Tours with the same symptoms as *lues inguinaria* (from the frequent seat of buboes in the groin). In Italy there was a great mortality in 543, but the most notable epidemic was in 565, which so depopulated the country as to leave it an easy prey to the Lombards. In 571 it is again recorded in Liguria, and in 590 a great epidemic at Rome is connected with the pontificate of Gregory the Great. But it spread in fact over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said; but it is possible the pestilence in England chronicled by Bede in the years 664, 672, 679, and 683 may have been of this disease, especially as in 690 *lues inguinaria* is again recorded in Rome. For the epidemics of the succeeding centuries we must refer to more detailed works.<sup>3</sup>

It is impossible, however, to pass over the great cycle of epidemics in the 15th century known as the Black Death. Whether in all the pestilences known by this name the disease was really the same may admit of doubt, but it is clear that in some at least it was the bubonic plague. Contemporary observers agree that the disease was introduced from the East; and one eye-witness, Gabriel de Mussis, an Italian lawyer, traced, or indeed accompanied, the march of the plague from the Crimea (whither it was said to have been introduced from Tartary) to Genoa, where with a handful of survivors of a Genoese expedition he landed probably at the end of the year 1347. He narrates how the few that had themselves escaped the pest transmitted the contagion to all they met.<sup>4</sup> Other accounts, especially old Russian chronicles, place the origin of the disease still further to the east in Cathay or China, where, as is confirmed to some extent by Chinese records, pestilence and destructive inundations are said to have destroyed the enormous number of thirteen millions. It appears to have passed by way of Armenia into Asia Minor and thence to Egypt and northern Africa. Nearly the whole of Europe was gradually overtaken by the pestilence. It reached Sicily in 1346, Constantinople, Greece, and parts of Italy early in 1347, and towards the end of that year Marseilles. In 1348 it attacked Spain, northern Italy and Rome, eastern Germany, many parts of France including Paris, and England; from England it is said to have been conveyed to the Scandinavian countries. In England the western counties were first invaded early in the year, and London in November. In 1349 we hear of it in the midlands; and in 1350, at least till 1357, it prevailed in parts of the country, especially in the towns. In 1352 Oxford

lost two-thirds of her academical population. The outbreaks of 1361 and 1368, known as the second and third plagues of the reign of Edward III., were doubtless of the same disease, though by some historians not called the black death. Scotland and Ireland, though later affected, did not escape.

The nature of this pestilence has been a matter of much controversy, and some have doubted its being truly the plague. But when the symptoms are fully described they seem to justify this conclusion, one character only being thought to make a distinction between this and Oriental plague, viz., the special implication of the lungs as shown by spitting of blood and other symptoms. Guy de Chauliac notes this feature in the earlier epidemic at Avignon, not in the later. Moreover, as this complication was a marked feature in certain epidemics of plague in India, the hypothesis has been framed by Hirsch that a special variety of plague, *pestis Indica*, still found in India, is that which overran the world in the 14th century. But the same symptoms (hæmoptysis) have been seen, though less notably, in many plague epidemics, even in the latest, that in Russia in 1878-79, and, moreover, according to the latest accounts, are not a special feature of Indian plague. According to Surgeon-General Francis (*Trans. Epidem. Soc.*, vol. v. p. 398) "hæmorrhage is not an ordinary accompaniment" of Indian plague, though when seen it is in the form of hæmoptysis. It seems, therefore, impossible to make a special variety of Indian plague, or to refer the black death to any such special form. Gabriel de Mussis describes it even in the East, before its arrival in Europe, as a bubonic disease.

The mortality of the black death was, as is well known, enormous. It is estimated in various parts of Europe at two-thirds or three-fourths of the population in the first pestilence, in England even higher, but some countries were much less severely affected. Hecker calculates that one-fourth of the population of Europe, or 25 millions of persons, died in the whole of the epidemics. It is hardly necessary to dwell upon the social results of this terrible mortality. In England great part of the country remained untilled, and the deficiency of labourers was such as to cause a sudden rise of wages, which, in spite of attempts to check it by legislation, is thought to have effected the final emancipation of the labouring class. On the other hand a great transfer of property to the church took place, with what results is well known.

In the 15th century the plague recurred frequently in nearly all parts of Europe. In the first quarter it was very destructive in Italy, in Spain (especially Barcelona and Seville), in Germany, and in England, where London was severely visited in 1400 and 1406, and again in 1428. In 1427 80,000 persons died in Dantzic and the neighbourhood. In 1438-39 the plague was in Germany, and its occurrence at Basel was described by *Æneas Sylvius*, afterwards Pope Pius II. In 1448-50 Italy (Kircher), Germany (Lersch, from old chronicles), France, and Spain were ravaged by a plague supposed to have arisen in Asia, scarcely less destructive than the black death. England was probably seldom quite free from plague, but the next great outbreak is recorded in 1472 and following years. In 1466 40,000 persons died of plague in Paris; in 1477-85 the cities of northern Italy were devastated, and in 1485 Brussels. In the fifteenth year of Henry VII. (1499-1500) a severe plague in London caused the king to retire to Calais.

The 16th century was not more free from plague than the 15th. Simultaneously with a terrible pestilence which is reported to have nearly depopulated China, plague prevailed over Germany, Holland, Italy, and Spain in the first decade of the century, and revived at various times in the first half. In 1529 there was plague in Edinburgh; in London in 1537-39, and again 1547-48; and also in the north of England, though probably not absent before. Some of the epidemics of this period in Italy and Germany are known by the accounts of eminent physicians, as Voets, Fracastor, Mercurialis, Borgarucci, Ingrassia, Massaria, Amici, &c.,<sup>5</sup> whose writings are important because the question of contagion first began to be raised, and also plague had to be distinguished from typhus fever, which began in this century to appear in Europe.

The epidemic of 1563-64 in London and England was very severe, a thousand dying weekly in London. In Paris about this time plague was an everyday occurrence, of which some were less afraid than of a headache (Borgarucci). In 1570 200,000 persons died in Moscow and the neighbourhood, in 1572 50,000 at Lyons; in 1563 and 1574 plague was at Edinburgh, and in 1570 at Newcastle. When, however, in 1575 a new wave of plague passed over Europe, its origin was referred to Constantinople, whence it was said to have spread by sea to Malta, Sicily, and Italy, and by land through the Austrian territories to Germany. Others contended that the

The works of English physicians of this period are of little medical value; but Lodge's *Treatise of the Plague* (London, 1603) deserves mention.

disease originated locally; and, indeed, considering previous history, no importation of plague would seem necessary to explain its presence in Europe. Italy suffered severely (Venice, in 1576, lost 70,000); the north of Europe not less, though later: London in 1580-82. In 1585 Breslau witnessed the most destructive plague known in its history. The great plague of 1592 in London seems to have been a part of the same epidemic, which was hardly extinguished by the end of the century, and is noted in London again in 1599. On the whole, this century shows a decrease of plague in Europe.

In the first half of the 17th century plague was still prevalent in Europe, though considerably less so than in the Middle Ages. In the second half a still greater decline is observable, and by the third quarter the disease had disappeared or was disappearing from a great part of western Europe. The epidemics in England will be most conveniently considered in one series. From this time onwards we have the guidance of the "Bills of Mortality" issued in London, which, though drawn up on the evidence of ignorant persons, are doubtless roughly true. The accession of James I. in 1603 was marked by a very destructive plague which killed 35,000 in London. In this and subsequent years the disease was widely diffused in England—for instance, Oxford, Derbyshire, Newcastle. It prevailed at the same time in Holland, and had done so some years previously in northern Germany. In the same year (1603) one million persons are said to have died of plague in Egypt. This plague is said to have lasted eight years in London. At all events in 1609 we have the second great plague year, with a mortality of 11,755. After this there is a remission till about 1620, when plague again began to spread in northern Europe, especially Germany and Holland, which was at that time ravaged by war. In 1625 (the year of the siege of Breda in Holland) is the third great London plague with 35,417 deaths, though the year 1621 was remarkably exempt, and 1626 nearly so. In 1630 was the great plague of Milan, described by Ripamonti.<sup>1</sup> In 1632 a severe epidemic, apparently plague, was in Derbyshire. 1636 is the fourth great plague year in London with a mortality of 10,460, and even in the next year 3022 persons died of the same disease. The same year 7000 out of 20,000 inhabitants of Newcastle died of plague; in 1635 it was at Hull. About the same time, 1635-37, plague was prevalent in Holland, and the epidemic of Nimeguen is celebrated as having been described by Diemerbroeck, whose work (*Tractatus de peste*, 1640, 1641-65) is one of the most important on the subject. The English epidemic was widely spread and lasted till 1647, in which year, the mortality amounting to 3597, we have the fifth epidemic in London. The army diseases of the Civil Wars were chiefly typhus and malarial fevers, but plague was not unknown among them, as at Wallingford Castle (Willis, "Of Fevers," *Works*, ed. 1681, p. 131) and Dunstar Castle. From this time till 1681 little was heard of plague in England, though it did not cease on the Continent. In Ireland it is said to have been seen for the last time in 1659.<sup>2</sup>

In 1656 one of the most destructive of all recorded epidemics in Europe raged in Naples; it is said to have carried off 300,000 persons in the space of five months. It passed to Rome, but there was much less fatal, making 14,000 victims only—a result attributed by some to the precautions and sanitary measures introduced by Cardinal Gastaldi, whose work, a splendid folio, written on this occasion (*Tractatus de urticula et pręliganda peste politica*, Bologna, 1654) is historically one of the most important on the subject of quarantine, &c. Genoa lost 60,000 inhabitants from the same disease, but Genoa remained untouched. The comparatively limited spread of this frightful epidemic in Italy at this time is a most noteworthy fact. Minorca is said to have been depopulated. Nevertheless the epidemic spread in the next few years over Spain and Germany, and a little later to Holland, where Amsterdam in 1663-64 was again ravaged with a mortality given as 50,000, also Rotterdam and Haarlem. Hamburg suffered in 1664.

*The Great Plague of London.*—The preceding enumeration will have prepared the reader to view the great plague of 1664-65 in its true relation to others, and not as an isolated phenomenon. The preceding years had been unusually free from plague, and it was not mentioned in the bills of mortality till in the autumn of 1664 (November 24) a few isolated cases were observed in the parishes of St Giles and St Martin's, Westminster, and a few occurred in the following winter, which was very severe. About May 1665 the disease again became noticeable, and spread, but somewhat slowly. Boghurst, a contemporary doctor, notices that it crept down Holborn and took six months to travel from the western suburbs (St Giles) to the eastern (Stepney) through the city. The mortality rapidly rose from 43 in May to 590 in June, 6137 in July, 17,036 in August, 31,159 in September, after which it began to decline. The total number of deaths from plague in that year, according to the bills of mortality was 68,596, in a population estimated at 150,000.<sup>3</sup>

out of whom two-thirds are supposed to have fled to escape the contagion. This number is likely to be rather too low than too high, since of the 6433 deaths from spotted fever many were probably really from plague, though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter; but in 1666 nearly 2000 deaths from plague are recorded.

According to some authorities, especially Hodges, the plague was imported into London by bales of merchandise from Holland, which came originally from the Levant; according to others it was introduced by Dutch prisoners of war; but Boghurst regarded it as of local origin. It is in favour of the theory that it spread by some means from Holland that plague had been all but extinct in London for some seventeen years, and prevailed in Holland in 1603-64. But from its past history and local conditions, London might well be deemed capable of producing such an epidemic. In the bills of mortality since 1603 there are only three years when no deaths from plague are recorded. The uncleanliness of the city was comparable to that of Oriental cities at the present day, and, according to contemporary testimony (Garencières, *Angliae Flagellum*, London 1617, p. 85), little improved since Erasmus wrote his well-known description. The spread of the disease only partially supported the doctrine of contagion, as Boghurst says:—"The disease spread not altogether by contagion at first, nor began only at one place and spread further and further as an eating sore doth all over the body, but fell upon several places of city and suburbs like rain." In fact dissemination seems to have taken place, as usual, by the conversion of one house after another into a focus of disease, a process favoured by the fatal custom of shutting up infected houses with all their inmates, which was not only almost equivalent to a sentence of death on all therein, but caused a dangerous concentration of the poison. The well-known custom of marking such houses with a red cross and the legend "God have mercy upon us!" was no new thing: it is found in a proclamation in the possession of the present writer dated 1611; and it was probably older still. Hodges testifies to the utility and injurious effects of these regulations. The lord mayor and magistrates not only carried out the appointed administrative measures, but looked to the cleanliness of the city and the relief of the poor, so that there was little or no actual want; and the burial arrangements appear to have been well attended to. The college of physicians, by royal command, put forth such advice and prescriptions as were thought best for the emergency. But it is clear that neither these measures nor medical treatment had any effect in checking the disease. Early in November with colder weather it began to decline; and in December there was so little fear of contagion that those who had left the city "crowded back as thick as they fled." As has often been observed in other plague epidemics, sound people could enter infected houses and even sleep in the beds of those who had died of the plague "before they were even cold or cleansed from the stench of the diseased" (Hodges). The symptoms of the disease being such as have been generally observed need not be here considered. The disease was, as always, most destructive in squalid, dirty neighbourhoods and among the poor, so as to be called the "poor's plague." Those who lived in the town in barges or ships did not take the disease; and the houses on London Bridge were but little affected. Of those doctors who remained in the city some eight or nine died, not a large proportion. Some had the rare courage to investigate the mysterious disease by dissecting the bodies of the dead. Hodges implies that he did so, though he left no full account of his observations. Dr George Thomson, a chemist and a disciple of Van Helmont, followed the example, and nearly lost his life by an attack which immediately followed.<sup>4</sup>

The plague of 1665 was widely spread over England, and was generally regarded as having been transmitted from London, as it appeared mostly later than in the metropolis, and in many cases the importation by a particular person could be traced. Places near London were earliest affected, as Brentford, Greenwich, Deptford; but in July or August 1665 it was already in Southampton, Sunderland, Newcastle, &c. A wider distribution occurred in the next year. Oxford entirely escaped, though the residence of the court and in constant communication with London. The exemption was attributed to cleanliness and good drainage.

After 1668 there was no epidemic of plague in London or any part of England, though sporadic cases appear in bills of mortality up to 1679; and a column filled up with "0" was left till 1703,

when it finally disappeared. The disappearance of plague in London was attributed to the Great Fire, but no such cause existed in other cities. It has also been ascribed to quarantine, but no effective quarantine was established till 1720, so that the cessation of plague in England must be regarded as spontaneous.

But this was no isolated fact. A similar cessation of plague was noted soon after in the greater part of western Europe. In 1666 a severe plague raged in Cologne and on the Rhine, which was prolonged till 1670 in the district. In the Netherlands there was plague in 1667-69, but there are no definite notices of it after 1672. France saw the last plague epidemic in 1668, till it reappeared in 1720. In the years 1675-84 a new plague epidemic appeared in North Africa, Turkey, Poland, Hungary, Austria, and Germany, progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 was very severe, causing 76,000 or probably more deaths. Prague in 1681 lost 83,000 by plague. Dresden was affected in 1680, Magdeburg and Halle in 1682,—in the latter town with a mortality of 4397 out of a population of about 10,000. Many North German cities suffered about the same time; but in 1683 the plague disappeared from Germany till the epidemic of 1707. In Spain it ceased about 1681; in Italy certain cities were attacked till the end of the century, but not later (Hirsch).

*Plague in the 18th Century.*—At the beginning of this period plague was very prevalent in Constantinople and along the Danube. In 1703 it caused great destruction in the Ukraine. In 1704 it began to spread through Poland, and later to Silesia, Lithuania, Prussia, and a great part of Germany and Scandinavia. In Prussia and Lithuania 233,000 persons perished; Dantzic, Hamburg, and other northern cities suffered severely. Copenhagen was attacked in 1710. In Stockholm there was a mortality of 40,000. Certain places near Brunswick (10° E. long.) marked the western limit of the epidemic; and cholera was arrested at the same spot in later years (Haeser).

At the same time the plague spread westward from the Danube to Transylvania and Styria, and (1713) appeared in Austria and Bohemia, causing great mortality in Vienna. Thence it passed to Prague and Ratisbon—to the former, possibly to the latter, almost certainly conveyed by human intercourse. This city (12° E. long.) was the western limit reached in this year. Haeser states that the plague disappeared everywhere in Europe after the great hurricane of February 27, 1714.

In 1717 plague raged severely in Constantinople; and in 1719 it made a fresh progress westwards into Transylvania, Hungary, Galicia, and Poland, but not farther (about 20° E. long.). It thus appears that each successive invasion had a more easterly western limit, and that the gradual narrowing of the range of plague, which began in the 17th century, was still going on.

This process suffered a temporary interruption by the outbreak of plague of southern France in 1720-22. In 1720 Marseilles became affected with an epidemic plague, the origin of which was attributed by some to contagion through the ship of a Captain Chataud which arrived, May 20, 1720, from Syria, where plague at that time prevailed, though not epidemically when he sailed. Six of the crew had died on the voyage to Leghorn, but the disease was declared not to be plague. Cases of plague occurred, however, on the ship, and on June 22 among porters unloading the cargo. Hence, according to believers in contagion, the disease passed to families in the "old town," the poorest and unhealthiest quarter. In the meantime other ships had arrived from Syria, which were put in quarantine. According to others the plague arose in Marseilles from local causes; and recently discovered data show that suspicious cases of contagious disease occurred in the town before the arrival of Chataud's ship.<sup>1</sup> Opinions were divided, and the evidence appears even now nearly balanced, though the believers in contagion and importation gained the victory in public opinion. The pestilence was fearfully severe. Thousands of unburied corpses filled the streets, and in all 40,000 to 60,000 persons were carried off. In December 1721 the plague passed away, though isolated cases occurred in 1722. It passed to, or at least broke out in, Arles and Aix in 1720, causing great mortality, but in Toulon not till 1721, when it destroyed two-thirds of the population. The epidemic spread generally over Provence, but not to other parts of France, notwithstanding that, as confessed by D'Antrehaus, consul of Toulon, a believer in the exclusive power of contagion, there were abundant opportunities. The disease was in fact, as in other cases, self-limited. In all 87,659 persons are said to have died out of a population of nearly 250,000.<sup>2</sup>

This great epidemic caused a panic in England, which led to the introduction (under Mead's advice) of quarantine regulations, never previously enforced, and also led to the publication of many

pamphlets, &c., beside Mead's well-known *Discourse on Pestilential Contagion* (London, 1720).

*Plague in Sicily in 1743.*—An outbreak of plague at Messina in 1743 is important, not only for its fatality, but as one of the strongest cases in favour of the theory of imported contagion. Messina had been free from plague since 1624, and the Sicilians prided themselves on the rigour of the quarantine laws which were thought to have preserved them. In May 1743 a vessel arrived from Corfu, on board of which had occurred some suspicious deaths. The ship and cargo were burnt, but soon after cases of a suspicious form of disease were observed in the hospital and in the poorest parts of the town; and in the summer a fearful epidemic of plague developed itself which destroyed 40,000 or 50,000 persons, and then became extinct without spreading to other parts of Sicily.

*Spread of Plague from the East.*—Independent of the episodes of Marseilles and Messina, the spread of plague from the East continued to exhibit the above-mentioned law of limitation. In 1738-44 the disease was in the Ukraine, Hungary, the borders of Carniola, Moravia, and Austria, extending along the Carpathians as far as Poland (20° E. long.), and also in Bukowina (25° E. long.). It lasted till 1745, and then disappeared from those parts for fifteen years. In 1755-57 plague prevailed in parts of European Turkey, whence it on one occasion extended into Transylvania, in the neighbourhood of Cronstadt, where it was checked (25° 5' E. long.).<sup>3</sup>

In 1770 a destructive plague arose in Moldavia during the Russo-Turkish War, and shortly afterwards in Wallachia, apparently endemic in the former country at least. It affected also Transylvania and part of Hungary, and still more severely Poland, but was confined to Podolia, Volhynia, the Ukraine, and the eastern part of Galicia (25° E. long.), not even penetrating as far as Warsaw. After destroying, it is said, 300,000 persons, and without being checked by any quarantine regulations, the plague died out finally in March 1771, being remarkable for its short duration and spontaneous limitation (Haeser).

In another direction the plague spread over Little Russia in 1770, and desolated Kieff, while in the next year it broke out in Moscow and produced one of the most destructive epidemics of modern times. More than 50,000 persons, nearly one-fourth of the population, were carried off.<sup>4</sup>

The remaining European plague-epidemics of the 18th century were inconsiderable, but on that very account noteworthy. Transylvania was again affected in 1785, Slavonia and Livonia (a district of eastern Galicia) in 1795-96 (25° E. long.), Volhynia in 1798. The disease, while reappearing in the seats of the terrible earlier epidemics, was more limited in its range and of shorter duration.<sup>5</sup> An epidemic in Dalmatia in 1783-84 is noteworthy in connexion with later outbreaks in the same region. In the last years of the century (1799-1800) there was a new epidemic in Syria and Egypt, where it affected the French and afterwards the English army.

*Plague in the 19th Century.*—This history divides itself naturally into two periods—1800-1845, and 1853 to the present time.

1800-1845.—Plague appeared at Constantinople in 1802-3, about the same time in Armenia (Kars), and in 1801 in Baghdad. It had prevailed since 1793 in Georgia and the Caucasus, and in 1803-6 began to spread from the north of the Caucasus into Russia, till in 1806 it was established at or near Astrakhan, and in 1807 reached Zareff, 200 miles higher up the Volga. These localities are interesting as being near those where plague appeared in 1877-78. It is also said to have entered the government of Saratoff, but probably no great distance.<sup>6</sup> The plague remained in the Caucasus and Georgia till 1819 at least. In 1828-31 it was in Armenia, and again in 1840-43, since which time it has not been heard of in that country.

In 1808 plague was at Constantinople, in 1809 at Smyrna. In 1812 was a more general epidemic affecting these places and also Egypt. An outbreak at Odessa is supposed to have been brought from Constantinople and thence to have passed to Transylvania. In 1813 a severe plague at Bucharest is supposed to have been brought from Constantinople. About the same time plague prevailed in Bosnia, and is supposed to have passed thence to Dalmatia in 1815. In 1814-15 it again appeared in Egypt, and once more invaded the continent of Europe in Albania and Bosnia. Two insular outbreaks, Malta in 1813 and Corfu in 1815, attracted much attention as being both thought to be cases of importation by sea-traffic,<sup>7</sup> and there seems good reason for this opinion.

A panic spread through Europe in 1815 in consequence of an outbreak in Noja on the eastern coast of Italy, its last appearance

villages, terrified at the accounts from Vetlanka, strictly isolated the sick, and thus probably checked the spread of the disease. But it evidently suffered a spontaneous decline. By the end of January there were no cases left in the district except at one village (Selitrannoje), where the last occurred on the 9th February. The total number of cases in Vetlanka, out of a population of about 1700, was 417, of whom 362 died. In the other villages there were about 62 deaths from plague, and not more than two or three cases of recovery. In consequence of the alarm excited by this last appearance of plague upon European soil, most European Governments sent special commissions to the spot. The British commissioners were Surgeon-Major Colvill and the present writer, who, like all the foreign commissioners, reached the spot when the epidemic was over. With respect to the origin of this epidemic, the possibility of its having originated on the spot, as in Resht and on the Euphrates in very similar situations, is not to be denied. An attempt was made to show that the contagion was brought home by Cossacks returning from the Turkish War, but on absolutely no evidence. In the opinion of the writer the real beginning of the disease was in the year 1877, in the vicinity of Astrakhan, and the sudden development of the malignant out of a mild form of the disease is no more than has been observed in other places. The Astrakhan disease may have been imported from Resht or Baku, or may have been caused concurrently with the epidemics of these places by some cause affecting the basin of the Caspian generally. But the conditions under which these mild or miasmatic forms of plague are spread are as yet unknown.

*Plague in India.*—It used to be held as a maxim that plague never appeared east of the Indus; nevertheless it has been observed during this century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar, and Cutch, "after three years of severe famine." It reappeared early next year, in the same locality, when it extended to Sind as far as Hyderabad, and in another direction south-east as far as Ahmedabad and Dholerah. But it disappeared from these parts in 1820 or early in 1821, and was not heard of again till July 1836, when a disease broke out into violence at the town of Pali in Marwar in Rajpootana. It spread from Pali to the province of Meywar, but died out spontaneously in the hot season of 1837, and has never been heard of again in that part of India. The origin of these two epidemics was obscure. No importation from other countries could be traced.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Gurwhal, a sub-district of Kumaon on the south-west of the Himalayas, on a high situation. In 1834 and 1836 other epidemics occurred, which at last attracted the attention of Government. In 1849-50, and again in 1852, the disease raged very severely and spread southward. In 1853 Dr Francis and Dr Pearson were appointed a commission to inquire into the malady. In 1876-77 another outbreak occurred, since which time no accounts of the epidemic have been received. The symptoms of this disease, called *maha murree* by the natives, are precisely those of Oriental plague. The feature of blood-spitting, to which much importance has been attached, appears to be not a common one. A very remarkable circumstance is the death of animals (rats, and more rarely snakes), which occurs at the outbreak of an epidemic. The rats bring up blood, and the body of one examined after death by Dr Francis showed an affection of the lungs. *Maha murree* is intensely communicable, but does not show much tendency to spread, since pilgrims who visit the mountain shrines are not affected and do not convey the disease. It is doubtless connected with uncleanness and poverty, but Dr Francis believes that the poison exists in the soil, which becomes more and more contaminated with it. The disease is pretty clearly endemic, not imported.<sup>1</sup>

It is remarkable that of late years reports have come of the occurrence of Oriental plague in China. It has been observed in the province of Yunnan since 1871, and also at Pakhoi, a port in the Tong-king Gulf, as lately as 1882,—but said to have prevailed there at least fifteen years. In Yunnan it appears to be endemic, though there are rumours of its having been brought from Burmah, and become more noticeable after the suppression of a rebellion in that province. The climate is temperate and the country partly mountainous. Some regard the disease as being conveyed from Pakhoi to Yunnan. In both places the symptoms were the same, of undoubted bubonic plague. It has always been noticed, as in India, that rats leave their holes and die at the beginning of an epidemic; and the same mortality has been observed among cats, dogs, cattle, ponies, deer, &c. At Pakhoi it recurs nearly every year.<sup>2</sup> Uncleanly habits have much to do with fostering the disease.

<sup>1</sup> On Indian plague, see Francis, *Trans. Epidem. Soc. Lond.*, vol. iv. pp. 407-8; John Murray, *ibid.*, vol. iv. part 2; J. N. Radcliffe, *Reports of Local Government Board*, 1873, 1876, 1877, and for 1879-80; *Parliamentary Papers*, 1879; Frederick Forbes, *On Plague in North-West Provinces of India*, Edinburgh, 1860 (Dissertation); Hirsch, *Handbuch der historischen-geogr. Pathologie*, vol. i. p. 209, 1860 (Eng. trans. by Creighton, London, 1883); Hecker's *Folkkrankheiten des Mittelalters*, Berlin, 1858, p. 101; Webb, *Pathologia Indica*, 2d ed., Calcutta, 1848.  
<sup>2</sup> See J. N. Radcliffe's *Report for 1879-80*, p. 45; Manson in *Reports of Imperial*

It thus appears that at the present time plague exists, or has existed within ten years, in the following parts of the world:—(1) Benghaz, Africa; (2) Persian Kurdistan; (3) Irak, on the Tigris and Euphrates; (4) the Asir country, western Arabia; (5) on the lower Volga, Russia; (6) northern Persia and the shores of the Caspian; (7) Kumaon and Gurhwal, India; (8) Yunnan and Pakhoi, China. Except Benghaz all these places show an eastward recession as compared with the old seats of plague known to us.

Benedictus, *De Observatione in Pestilentia*, 4to, Ven., 1493; Nicolaus Massa, *De Febre Pestilentiali*, 4to, Ven., 1556, &c.; (Floravanti, *Regimento della Peste*, 8vo, Ven., 1565); John Woodall, *The Surgeon's Mate*, folio, London, 1659; Van Helmont, *Tumulus Pests*, 8vo, Cologne, 1644, &c.; (Muratori, *Trattato del Governo della Peste*, Modena, 1714); John Howard, *An Account of Lazarettos in Europe*, &c., 4to, London, 1769; Patrick Russell, *A Treatise of the Plague*, 4to, London, 1791; Thomas Hancock, *Researches into the Laws of Pestilence*, 8vo, London, 1821; (Fodéré, *Leçons sur les Epidémies*, &c., 4 vols. 8vo, Paris, 1822-24); (Séguin Duperron, *Recherches Historiques, &c., sur la Peste*, 1837); Bulard, *La Peste Orientale*, 8vo, Paris, 1839; Griesinger, *Die Infectiouskrankheiten*, 2d ed., 8vo, Erlangen, 1864.

(J. F. P.)

**PLAICE.** (*Pleuronectes platessa*), a species of Flat-fish, common on the coasts of northern Europe from Iceland to the Bay of Biscay. It is readily recognized by the yellow or orange-coloured spots which are placed in a row along the dorsal and anal fins, and scattered over the body. The eyes are on the right side, and the teeth in the jaws compressed and truncate. The scales are minute and smooth. In the dorsal fin from sixty-seven to seventy-seven rays may be counted, in the anal from fifty to fifty-seven. Plaice, like other flat-fishes, prefer a sandy flat bottom to a rocky ground, and occur in suitable localities in great abundance; and, as they belong to the better class of fishes for the table, immense quantities are brought to the market. They spawn early in spring, and are in finest condition in the month of May. Individuals of seven or eight pounds weight are considered fish of large size, but specimens of double that weight have been caught. Plaice grow quickly and are tenacious of life; and, as they thrive in brackish water, their culture in littoral back-waters would seem to be deserving of every attention.

**PLAINFIELD**, a city of the United States, in Union county, New Jersey, lies at the foot of Mount Orange, and on the left side of the Green Brook, a tributary of the Raritan. It may to some extent be regarded as a residential suburb of New York, from which it is distant 24 miles by the Central Railroad. The local manufactures—hats and clothing—are comparatively trifling. Laid out in 1735 and made a city in 1869, Plainfield had 5095 inhabitants in 1870 and 8125 in 1880. A railroad consisting of narrow iron bands nailed down to wooden logs was constructed between Plainfield and Elizabeth as early as 1838. Two miles to the south-west is Washington's Rock, a coign of vantage from which the general used to watch the British movements.

**PLAIN SONG, or PLAIN CHANT** (*Gregorian Music*; Lat. *Cantus planus*; Ital. *Canto Gregoriano*; Fr. *Plain Chant*), a style of music, easily recognizable by certain strongly-marked characteristics, some very ancient fragments of which are believed to have been in use under the Jewish dispensation from a remote period, and to have been thence transferred to the ritual of the Christian church.

The theories advanced as to the origin of this solemn form of ecclesiastical music are innumerable. The most widely-spread opinion is that the older portion of it originated with the Psalms themselves, or at least sprang from the later synagogue music. Another theory traces the origin of plain song to the early Greeks; and the supporters of this view lay much stress on the fact that the scales in which its melodies are composed are named after the old Greek "modes." But, beyond the name,

*Chinese Customs*, special series No. 2, for half-year ended 31st March 1878, 15th issue, Shanghai; Lowry, "Notes on Epidemic Disease at Pakhoi," 1882, *ibid.*, 24th issue, p. 31.

<sup>3</sup> Those in square brackets [ ] have not been seen by the writer.

no connexion whatever exists between the two tonalities, which bear not the remotest resemblance to each other. Less reasonable hypotheses attribute the origin of plain song to the Phœnicians, to the Egyptians, to the early Christian converts, and to the musicians of the Middle Ages. These divergent views, however, though entirely hypothetical, are defended by arguments so voluminous that for the elucidation of the subject we must content ourselves with referring the reader to the works of Gerbert, P. Martini, P. Kircher, Mersennus, P. Lambillotte, the Abbé Raillard, Coussemaker, Kiesewetter, Jakob, Ambros, and other authors, who have treated it at great length.

The earliest important fact upon which we can rest with absolute confidence is that towards the close of the 4th century Ambrose of Milan, fearing the loss or corruption of the venerable melodies which up to that time had been preserved to the church by means of oral tradition only, endeavoured to restore them as nearly as possible to their primitive purity, and at the same time to teach the clergy to sing them with greater precision than had previously been attempted. A still more extensive work of the same nature was undertaken, two centuries later, by Pope Gregory the Great. And thus arose two schools of ecclesiastical music, still known as the "Ambrosian" and the "Gregorian chant,"—the first of which is now practised only in the diocese of Milan, while the latter is universally accepted as the authorized "Roman use." In order to explain the essential differences existing between these two schools, we must here describe in detail some of the peculiar characteristics of plain song to which allusion has been made.

The melodies which collectively form the *repertoire* of plain chant are not written in modern major and minor scales, but in certain tonalities bearing names analogous to those of the early Greek "modes," though constructed on very different principles. Of these "modes," fourteen exist in theory, though twelve only are in practical use. The intervals of each "mode" are derived from a fundamental sound, called its "final."<sup>1</sup> The compass of each mode comprises eight sounds,—that of the first, third, fifth, seventh, ninth, eleventh, and thirteenth "modes," extending to the octave above the "final," and that of the second, fourth, sixth, eighth, tenth, twelfth, and fourteenth, extending from the fourth note below the final to the fifth note above it. Consequently, the "finals" of the first series, called the "authentic modes," occupy the lowest place in each system of sounds, and those of the second series, called the "plagal modes," the middle place,—the same "final" being common to one "authentic" and one "plagal mode." The following table exhibits the entire system, expressed in the alphabetical notation peculiar to modern English music,—the "final" being indicated in each case by an asterisk, and the position of the semitones, from which each mode derives its distinctive character, by brackets.

## Authentic Modes.

1. Doian, \*D, E, F, G, A, B, C, D.
3. Phrygian, \*E, F, G, A, B, C, D, E.
5. Lydian, \*F, G, A, B, C, D, E, F.
7. Mixolydian, \*G, A, B, C, D, E, F, G.
9. Æolian, \*A, B, C, D, E, F, G, A.
11. Locrian, \*B, C, D, E, F, G, A, B.
13. Ionian, \*C, D, E, F, G, A, B, C.

## Plagal Modes.

2. Hypodorian, A, B, C, \*D, E, F, G, A.
4. Hypophrygian, B, C, D, \*E, F, G, A, B.
6. Hypolydian, C, D, E, \*F, G, A, B, C.
8. Hypomixolydian, D, E, F, \*G, A, B, C, D.
10. Hypoæolian, E, F, G, \*A, B, C, D, E.
12. Hypolocrian, F, G, A, \*B, C, D, E, F.
14. Hypoionian, G, A, B, \*C, D, E, F, G.

Nos. 11 and 12 in this series are rejected, for technical reasons into which we have not space to enter; they are practically useless.<sup>2</sup>

Of these modes Ambrose used four only—the first four

"authentic modes," now numbered 1, 3, 5, and 7. Gregory acknowledged, and is said by some historians of credit to have invented, the first four "plagal modes,"—Nos. 2, 4, 6, and 8. The use of the remaining "modes," except perhaps the ninth, was not formally authorized until the reign of Charlemagne, who published an official decision upon the subject. In one or other of the twelve "modes" recognized by this decision, every plain-chant melody is composed. The number of such melodies preserved to us the genuineness of which is undoubted is immensely large; and the collection is divided into several distinct classes, the most important of which are the melodies proper to the *Psalm-Tones* and *Antiphons*; the *Ordinarium Missæ*, the *Introits*, *Graduals*, and *Offertoria*; the *Præfationes*, *Versiculi*, and *Responsoria*; the *Hymns* and *Sequences*; and the *Lamentationes*, *Exultet*, and other music used in Holy Week.

Of these classes the most interesting by far is that which includes the psalm-tones, or psalm-tunes, called by modern English historians, the "Gregorian tones." The oldest of these are tones 1, 3, 5, and 7, as sung by Ambrose. The antiquity of tones 2, 4, 6, and 8 is less firmly established, though there is no doubt that Gregory the Great sanctioned their use on strong traditional evidence. In addition to these, a peculiarly beautiful melody in mode 9, known as the *Tonus peregrinus*, has been sung from time immemorial only to the psalm *In exitu Israel*. The oldest version of this melody now extant is undoubtedly to a certain extent impure; but tradition imputes to it a very high antiquity, and even our doubts as to the authenticity of the now generally accepted reading extend only to one single note. A widely-accepted tradition points out this melody as the tune sung to *In exitu Israel*, as part of the Great Hallel (see *PSALMS*), which is generally (but hardly rightly) identified with the hymn sung by our Lord and His apostles immediately after the institution of the Last Supper.

One very powerful argument in favour of the Jewish origin of the psalm-tones lies in the peculiarity of their construction. We are not aware that this argument has ever been previously brought forward; but it is impossible to subject the venerable melodies to minute examination without observing their perfect adaptation to the laws of Hebrew poetry, as opposed to those which governed Greek and Latin verse. The division of the tune in every case, without exception, into two distinct strains, exactly balancing each other, points assuredly to the intention of singing it to the two contrasted phrases which, inseparable from the constitution of a Hebrew verse, find no place in any later form of poetry. And it is very remarkable that this constructional peculiarity was never imitated, either in the earliest hymns or antiphons we possess or in those of the Middle Ages,—evidently because it was found impossible to adapt it to any mediæval form of verse—even to the *Te Deum*, which, though a manifest reproduction of the Hebrew psalm, was adapted by Ambrose to a melody of very different formation, and naturally so since so many of its phrases consist of a single clause only, balanced in the following verse. This peculiarity now passes for the most part unnoticed; and the *Te Deum* is constantly sung to a psalm-tone, very much to the detriment of both. But in the Middle Ages this abuse was unknown; and so it came to pass that, until the "School of the Restoration" gave birth, in England, to the single chant, avowedly built upon the lines of its Gregorian predecessor, and a somewhat later period to the double one, so constructed as to weld two verses of the psalm into one, often with utter disregard to the sense of the words, the venerable psalm-tones stood quite alone—the only melodies in existence to which the psalms could

<sup>1</sup> Analogous to the tonic or key-note of the modern scale.

<sup>2</sup> For fuller information on the subject see the article "Modes, the Ecclesiastical," in Sir G. Grove's *Dictionary of Music*.

be chanted. And so intimate is the adaptation of these plain-chant melodies to the rhythm as well as to the sense of the sacred text, even after its translation into more modern languages, so strongly do they swing with the one and emphasize the other, that it is difficult to believe that the composition of the music was not coeval with that of the poetry.

Next in antiquity to the psalm-tones are the melodies adapted to the antiphons, the offertoria, the gradualls, and the introits, sung at high mass. Those proper to the *Ordinarium Missæ* are probably of later date. Those belonging to hymns and sequences are of all ages. Among the latest we possess—perhaps the very latest of any great importance—is that of *Lauda Sion*,—a very fine one, in modes 7 and 8, adapted to the celebrated sequence written by Thomas Aquinas about 1261.

To the melodies adapted to the *Lamentationes* and the *Exultet*, as sung in the Church of Rome during Holy Week, it is absolutely impossible to assign any date at all. All we know is that they are of extreme antiquity, and beautiful beyond all description. The melody of *Exultet* is, indeed, very frequently cited as the finest example of plain song in existence.

To assert that melodies so old as these have been handed down to us in their original purity would be absurd. But the presence of corruption rarely passes undetected by the initiated; and vigorous efforts have been made from time to time to purify the received text by reference to the oldest and most trustworthy MSS. attainable. Such an effort was made on a very extensive scale by the "Congregation of Rites," at the instigation of Pope Pius IX., in the year 1868; and the labours of that learned body, still in active progress, are doing all that can now be done towards the restoration of plain chant to the highest state of purity possible in the present stage of its existence.

(W. S. R.)  
**PLANARIANS.** The name *Planaria* was first applied by O. F. Müller in his *Prodromus Zoologiæ Danicæ* (1776) to a group of worms, inhabitants of fresh and salt water, characterized, so far as was then known, by a flattened leaf-like form. Ehrenberg in 1831 changed this name to *Turbellaria* on account of the cilia with which the body is furnished, by means of which the worms create a whirlpool in the surrounding water. The extent of this group was subsequently more restricted, and at present the name *Turbellaria* is applied to all those (mainly free-swimming) Platyhelminths whose body is clothed externally with a ciliated epidermis (fig. 9), and which possess a mouth and (with the exception of one division) an alimentary canal, but are without an anus. The Turbellarians, excluding the NEMERTINES (*q.v.*), which until recently were classed with them, form an order of the class *Platyhelminthes*, and the old name *Planaria* is now confined to a group of the fresh-water representatives of this order.

**Size and External Characters.**—Many forms of the Turbellarians are so minute as to be hardly visible with the naked eye, while others attain to a length of several inches, and a land Planarian of no less than 9 inches in length has been described by Moseley. The freshwater forms are generally small, the largest representatives of the order being marine or terrestrial. The smaller species are mostly cylindrical, or convex dorsally and flat ventrally; the anterior extremity is commonly truncated and the posterior extremity pointed (fig. 1, *a*, *b*). The larger aquatic forms are thinner in proportion to the increasing surface of the body, so that they come to resemble thin leaf-like lamellæ (*d*), while the large land Planarians instead of increasing in superficies grow in length (*e* and *f*), so that they may be best compared to leeches. The larger aquatic forms are frequently provided

with tentacles in the shape of paired finger-like processes or ear-like folds of the anterior part of the body (*d* and *g*); sometimes the tentacles are papillary outgrowths of the dorsal surface; the

land Planarians are often to be distinguished by a crescent-shaped area at the fore end of the body, which is separated off from the rest (*f*). In many cases the whole dorsal surface is beset with papillæ (*d*). The aperture of the mouth varies greatly in its position; sometimes it is situated at the anterior extremity, sometimes in the middle of the ventral surface of the body, occasionally quite close to the posterior extremity; the single common or distinct male and female generative apertures are also situated upon the ventral surface of the body, and the former in rare cases open in common with the mouth; the genital apertures always lie behind the mouth. Many Turbellarians have a sucker which serves to attach the animal to surrounding objects, or to another individual during copulation.

**Integument.**—The integument is composed of a single layer of ciliated epithelium; between the cilia there are often long flagella and stiff tactile hairs and even (in a single instance) chitinous spines; these latter must be regarded as local thickenings of the firm cuticle which covers the epidermic cells. The epidermic cells are flat or columnar, and are united to each other by smooth opposed margins or by denticulate processes which fit into similar processes in the adjacent cells (fig. 2). Sometimes the epidermic cells are separated by an interstitial nucleated tissue. The structure and functions of the cells of the epidermis differ, and four varieties are to be found:—(*a*) indifferent ciliated cells; (*b*) cells containing certain definite structures (rhabdites, nematocysts); (*c*) gland cells; and (*d*) glutinous cells (Klebzellen). The rhabdites are refracting homogeneous rod-like bodies, of a firm consistency, which are met with in most Turbellaria, and often fill all the cells of the epidermis; they are not always found entirely within the cells, but the extremity often projects freely on to the exterior of the body. They are readily extruded from the cells by pressure, and are often found in great abundance in the mucus secreted by the glandular cells (many Turbellarians, like snails, deposit threads of mucus along their track); in this case the epidermic cells become perforated like a sieve. In many Turbellarians the rhabdites are chiefly massed in the anterior part of the body; frequently there are several varieties of rhabdites in one and the same species,—some being pointed at both ends, others cylindrical with truncated extremities. These structures are either formed directly in the ordinary epidermic cells as a kind of secreted product of the cell, or in special formative cells which lie beneath the integument and are connected with the epidermic cells by protoplasmic filaments, by means of which the rhabdites reach the surface of the body. These cells must be regarded as epidermic

FIG. 1.—*a*, *Conrotula paradoxa*, Oe.; *b*, *Vortex viridis*, M. Sch.; *c*, *Monotus fuscus*, Gff.; *d*, *Thysanozoon brochii*, Gr., with elevated anterior extremity (after Joh. Schmidt); *e*, *Rhynchodemus terrestris*, O. F. Müller (after Kennel); *f*, *Dipatium ceres*, Moe. (after Moseley); *g*, *Polycelis cornuta*, O. Sch., attached by the pharynx (*ph*) to a dead worm (after Johnson). All the figures of natural size, and viewed from the dorsal surface.

cells which have become disconnected with the epidermis itself, and wandered into the subjacent parenchyma. The function of the rhabdites seems to be to support the tactile sense. In rare instances nematocysts are present which in structure and development entirely resemble those of the *Calentaria* (see vol. xii. p. 550). Very commonly structures known as pseudo-rhabdites are present; these have a rod-like form, but instead of being homogeneous are finely granular; they are an intermediate step between the rhabdites proper and a granulated secretion occasionally thrown off by the gland cells. The unicellular glands are either situated among the epidermic cells or in the parenchyma, in which case they are connected with the exterior only by the excretory duct. A peculiar modification of the epidermic cells are the so-called "glutinous cells," which occur on the ventral surface or at the hinder end of the body of many Turbellarians, and compensate for the suckers; the surface of these cells is furnished with numerous minute processes by means of which and a sticky secretion the animals can attach themselves to surrounding objects. Sometimes the epidermic cells contain calcareous concretions, and very commonly pigment is found either in the cells themselves or within the interstitial tissue. The colours of Turbellarians are, however, not always due to the pigment of the epidermis but to pigment contained in the parenchyma. Beneath the epidermis is a basement membrane (fig. 2, *bm*) which is in

FIG. 2.—Integument of *Mesostoma isigla*, O. Sch. On the right hand is the epidermis (*e*) with perforations (*p*) through which the rhabdites (*st*) project. Beneath this the basement membrane (*bm*), and beneath this again the muscular layers consisting of circular (*rm*), diagonal (*dm*), and longitudinal (*lm*) fibres.

some cases very delicate and structureless, and in other cases much thicker and enclosing branched cells; this membrane is attached more firmly to the subjacent tissue than to the epidermis. Since this tissue is the strongest in the body, and serves as a surface of attachment for the muscles, it has been termed by Lang a skeletal membrane.

The third section of the integument is formed by the muscular layers. These form a continuous covering to the rest of the body, but their arrangement and thickness are very different in different forms. In the smaller species (*Rhabdocelida*) there are two layers, an outer circular and an inner longitudinal, only in a few cases the circular layer is external to the longitudinal; sometimes there are three distinct layers, as in fig. 2, where a diagonal layer is interposed. The larger forms (*Dendrocalida*) have a much more complicated muscular system: in the most differentiated forms there are six separate layers (two circular, two diagonal, and two longitudinal), which are, however, always less developed upon the dorsal than upon the ventral surface in that the thickest layer of the ventral surface (the innermost longitudinal) is absent or very feebly developed upon the dorsal side. Besides the

integumentary muscular system, there are also found dorso-ventral muscular bands which traverse the whole body from the dorsal to the ventral basement membrane, being branched at both extremities, and the special muscles of the pharynx, genital organs, and suckers.

The perivisceral cavity, bounded by the integument and traversed by the dorso-ventral muscles, contains the organs of the body—alimentary canal, excretory system, nervous system, and genital glands. The space left between these organs is filled with parenchyma; the latter varies much in appearance and is very difficult to study. Generally it consists of a network of fibres and trabeculae, which contain nuclei, and between which is a system of cavities filled during life with the perivisceral fluid. These cavities are generally but few in number and vary with the stronger or feebler development of the reticulum; they occasionally contain free cells.

**Alimentary Canal.**—All Turbellarians are furnished with a mouth, which, as there is no anus, serves both to take in nutriment and expel the undigested remains of food. The alimentary canal consists of a muscular pharynx and an intestine. The pharynx (figs 3, 5 to 8, *ph*) is cylindrical in form, rather complicated in structure, and surrounded by a muscular sheath, which opens on to the exterior by the mouth (*m*). Often the pharynx consists merely of a circular fold lying within the pharyngeal pouch (fig. 8); it can be protruded through the mouth and acts like a sucker, so that the animal can fasten itself upon its prey and draw it into the intestine by suction. At the junction of the pharynx with the intestine open the salivary glands, which are frequently large and well-developed (fig. 5, *s*). The intestine (*i*) has a very characteristic form in the different sections, and has long served to divide the *Turbellaria* into two groups:—(1) *Rhabdocelida*, with a straight unbranched intestine (figs. 5, 6), and (2) *Dendrocalida*, with a branched intestine (figs. 7, 8). In the latter group Lang has recently called attention to further differences that exist in the form of the intestine: in the *Tricladida* (fig. 7) there is no central "stomach," but three equally-sized intestinal branches (which have secondary ramifications) unite together to open into the pharynx; in the second group, the *Polycladida* (fig. 8), there is a median stomach (*st*), from which numerous intestinal branches arise; this stomach communicates directly with the pharynx; the branches of the intestine are much ramified and often form an anastomosing network. The epithelium of the intestine is a single layer of cells generally not ciliated, capable of protruding amoeboid processes by which the food is absorbed; the digestion of these animals is intracellular. Sometimes a muscular coat surrounds the intestine, the lumen of which is thus capable of being totally or partially contracted. To the above-mentioned divisions of the group, distinguished from each other by the varying form of the alimentary tract, another has been added, viz., the *Acala* (Ulianin), which are characterized by the entire absence of any intestine. In these forms (fig. 4) the mouth leads directly into the parenchyma of the body by a short tube which is merely an invagination of the integument; the parenchyma is a syncytium, consisting of a soft protoplasmic mass with scattered nuclei, which represents the elements of the intestine and the body parenchyma (ento- and mesoderm) completely fused and without any traces of differentiation. This fact, as well as the disappearance of a nervous and excretory system, reduces the *Acala* to the lowest position not only among the *Turbellaria*, but among the whole group of the *Vermes*.

**Excretory System.**—The excretory system of the Turbellarians is quite similar to that of the Trematodes and Cestoids; it consists of (1) the main trunks with their

external aperture, (2) the secondary branches of these, and (3) the excretory cells with the fine tubules leading from them. Rarely is there but a single main excretory trunk present opening at the hinder end of the body (*Stenostoma*); generally there are a pair of such trunks which open in common at the hinder end of the body, or separately (most *Rhabdocoela*), or by the mouth (fig. 3).

In the *Tricladida* there are two or four lateral trunks present which open by a number of pores arranged in pairs upon the dorsal surface of the body; the same appears to be the case in the *Polycladida*. The main trunks of the excretory system are generally much twisted in their course, and anastomose with each other; they receive the fine tubules either directly or, as in the *Rhabdocoela*, there is a network of secondary tubules interposed. The excretory cells are pear-shaped; they are branched and furnished with a nucleus and a large vacuole which is directly continuous with the lumen of the tubule; from the boundary wall of the vacuole springs a single flagellum, which depends into the lumen of the tubule and is capable of active movement. Lang discovered in a marine form of the *Tricladida* (*Gunda*) similar vacuolated cells with a single flagellum among the epithelial cells of the intestine, and came to the conclusion that the excretory cells were on that account derived from the epithelium of the intestine. The movements of the excretory fluid towards the external pore are directed by this flagellum as well as by cilia developed upon the walls of the fine tubules; the motion of all these cilia is such as to drive the contents of the tubules towards the excretory pore. The main trunks of the excretory system are either sparsely (*Tricladida* according to Jijima) or completely (*Polycladida* according to Lang) lined with cilia.

**Nervous System.**—The central organ of the nervous system, the brain (*cn*), is a double ganglion at the anterior end of the body, and has been noticed in all the known forms with the exception of the *Acoela*. It is situated in front of or above the pharynx; in those species in which a process of the intestine extends beyond the region of the brain (*cf.* figs. 7 and 8 viewed from the ventral surface) it is placed below this. In such cases there is sometimes a commissure encircling the prolongations of the intestine. Each of the two ganglia gives off a strong longitudinal nerve cord (figs. 5-8, *ln*) from which arise branches going to the various organs of the body. The structure of the nervous system is somewhat different in the *Rhabdocoela*, *Tricladida*, and *Polycladida*. In the first group (figs. 5, 6) the two longitudinal cords and their branches are the most feebly developed, and there is but rarely (*Monostoma*, *Monetus*) a transverse commissure uniting the longitudinal cords. These cords are very large in the *Tricladida*, where the brain is to be regarded as a simple thickening of them; in this group there are numerous transverse commissures between the longitudinal nerve cords (fig. 7), and the nerves arising from them and passing to the periphery form a subcutaneous nerve plexus within the muscular coat. Lang has observed a similar nerve plexus in the *Polycladida*, the central nervous system of which differs from that of the *Tricladida* in that a number of stout nerve cords radiate outwards from the brain as well as the

two longitudinal cords; they are all united together by

FIG. 3.—Main trunks of the excretory system of *Mesostoma ehrenbergii*, O. Sch. Open on to the exterior through the mouth. *ph*, pharynx.

FIG. 4.

FIG. 5.—Plan of a Rhabdocoelous Turbellarian. *bc*, bursa copulatrix; *cn*, brain; *e*, eye; *g*, germarium; *i*, intestine; *ln*, longitudinal nerve trunk; *m*, mouth; *ph*, pharynx; *rs*, receptaculum seminis; *s*, salivary gland; *t*, testis; *u*, uterus (containing an egg); *v*, yolk gland; *vs*, vesicula seminalis; *δ*, male copulatory organ; *♀*, common sexual aperture; *bc*, bursa copulatrix.

numerous commissures, and a network is thus formed which extends throughout the body.

FIG. 6.

FIG. 6.—Plan of an Allocoelous Turbellarian. Lettering as in fig. 5.

FIG. 7.

FIG. 7.—Plan of a Tricladid. *i*<sub>1</sub>, anterior, and *i*<sub>2</sub>, *i*<sub>3</sub>, paired posterior branches of intestine; *od*, oviduct; *te*, tentacle; *vd*, vas deferens; *δ*, male, and *♀*, female copulatory organ. Other letters as in fig. 5.

**Sense Organs.**—These are represented by tactile organs,

auditory organs (otoliths), and eyes. The whole surface of the body is very sensitive and (e.g., in the *Polysadida*) contains cells which end in tufts of fine hairs, so that certain regions thus become specially sensitive and serve as tactile organs. The anterior pointed extremity of the body in the *Rhabdonela* is characterized by an abundant development of rhabdites and tactile hairs, and thus becomes a special tactile organ; in other cases this region of the body is transformed into a conical tactile proboscis which can be retracted into a sheath (*Proboscida*). In the freshwater *Tricladida* the anterior margin of the head is richly innervated, and is beset with a special row of tactile cells which contain no rhabdites; in the terrestrial forms of the same family (*Bipalium*) Moseley has described a row of papillae along the crescent-shaped anterior extremity which can be

scattered over the whole of the anterior margin of the body and upon the tentacles. The eyes are always situated beneath the integument within the parenchyma, sometimes directly upon the brain or connected with it by special optic nerves. In its simplest form the eye is a pigmented spot with or without a refractory lens-like body; the more complicated eyes consist of a pigmented sheath containing a number of refracting rods which are connected at their outer extremity with a series of retinal cells, one to each rod; the retinal cells are prolonged into a nerve thread running to the brain; the arrangement of the visual elements is therefore precisely the same as in the vertebrate eye. Of great interest is the fact that in the *Polychadida* the number of eyes increases with the growth of the animal, and Lang has shown that the eyes increase in number by actual division. On the other hand Carrière has discovered by experimenting with certain freshwater *Tricladida* that the compound eyes (those containing a number of rods) are formed by the coalescence of several simple eyes. Only a single eye is found in the *Monotida*, which has the form of a simple pigment spot in front of the ocellus.

Auditory organs are found in the shape of vesicles filled with fluid and containing circular, lenticular or spindle-shaped otoliths formed of carbonate of lime. Otolithic vesicles of this kind are found in many *Rhabdonulidæ* (*Aicula*, *Monotida*, fig. 4, c) embedded in a depression on the anterior surface of the brain. In the *Dendrocnidæ* these organs are but rarely present.

As a sensory organ of unknown function must be mentioned the paired lateral ciliated grooves which are met with on either side of the brain in many *Rhabdo* (fig. 9, c): they are also found commonly in *Nemertines* (q. v.).

[illegible]

extended and form tactile organs; between the papillae are peculiar ciliated grooves connected with nerves. In the *Polychadida* there are tactile cells with stiff hair-like processes on the summit of the dorsal papillae and the various tentacular structures; the tentacles in this family also serve to support the eyes.

The majority of the Turbellarians possess eyes; the *Rhabdonolida* commonly have two or four, as also have the *Tridacnida*; the latter, however, are in some instances furnished with a greater number arranged in a continuous row round the anterior end of the body; in the *Polycladida* there are from fourteen to several hundred eyes arranged in two symmetrical groups round the brain or;

until fertilization is accomplished. A further division of labour is brought about by the presence of two diverticula of the atrium genitale, one of which serves as a bursa copulatrix (fig. 5, bc) and the other as a receptaculum seminis (rs) in the same sense as the equivalent organs of insects. In the place of a special receptaculum seminis the efferent duct of the ovary is often (*Mesostomida*) metamorphosed into a chamber to contain the semen. In the *Tricladida* and *Polycladida* the female efferent duct is often differentiated into a muscular vagina which closely resembles the penis (figs. 7, 8, ♀).

Finally, the female generative apparatus is furnished with a number of glands which have been termed cement glands, albuminiparous glands, and shell glands.

The male sexual glands (figs. 4-8, ♂) resemble the ovaries in being either compact tubular (fig. 5) or follicular (figs. 4, 6, 7, 8) structures. The vasa deferentia (vd) are often widened out into vesiculae seminales (figs. 4, 6, rs); or there are special vesiculae seminales present, formed by a portion of the penis (fig. 5, rs). In the male organ of copulation there is frequently found in addition to the spermatozoa an accessory granulated secretion produced by special glands, but of unknown function.

The muscular penis, especially in the *Rhabdocela*, has a number of chitinous spines and hooks which serve to assist the animal in maintaining a firm hold during copulation, but also in capturing and retaining its prey. In *Macrorhynchus helgolandicus*, Giff., there is a peculiar poison dart connected with the male copulatory organ which only serves the latter purpose. Very remarkable is the opening of the penis into the mouth cavity in *Stylostomum* (*Polycladida*) and *Prorhynchus* (*Rhabdocela*), and also the existence of several (2-15) pairs of male copulatory organs and genital apertures in certain *Polycladida*.

The spermatozoa vary much in form, especially in the *Rhabdocela*, where frequently the species of one and the same genus are distinguished by the different form of the spermatozoa. Copulation in the Turbellarians is generally reciprocal; only in those cases where both summer and winter ova (see above) are formed do the former arise from self-fertilization; the latter are the result of the copulation of two individuals. The fertilization of the ova always takes place in the atrium genitale. Many Turbellarians, especially the *Acala*, display the phenomenon known as "successive hermaphroditism," the male organs of an individual attain to maturity first, and the female organs become ripe subsequently. During copulation, therefore, one individual is physiologically a male and the other a female.

Asexual generation is met with only in the *Microstomida*; it takes the form of transverse division accompanied by budding. The posterior third of the body becomes separated off by a septum running from the gut to the integument and an external furrow corresponding to this; this part of the body grows in length until it equals the anterior portion. By further repetition of this double procedure of separation and equalization there, chains of 4, then 8, 16, and 32 buds are formed, which remain attached (fig. 9), and, although fresh mouth apertures ( $m'$ ,  $m''$ ,  $m'''$ ) have been formed, are still in communication by the intestinal lumen; this becomes closed before or after the several buds break off from their connexion with each other. Throughout the whole summer chains of zooids are met with; in autumn this asexual division probably ceases to occur; the several individuals become sexually mature, separate from each other, and lay eggs which remain quiescent during the winter and in the spring develop into fresh individuals reproducing asexually.

**Development.**—The study of the development of the Turbellarians is unfortunately not very far advanced, particularly among the small *Rhabdocelida*, which are extremely difficult to investigate, and about which hardly any developmental facts are known. The larger freshwater *Tricladida* and the *Polycladida* on the contrary have been recently very fully investigated. The *Rhabdocela* and the *Tricladida* appear to develop directly without any metamorphosis, while a great part of the *Polycladida* undergo a metamorphosis and pass through a larval condition, during which they are furnished with provisional ciliated processes (fig. 10); the *Acala* have also a free larval form; pelagic larvae with a coat of long cilia apparently belonging to this group have been observed by Ulianin. The segmentation of the ovum is total, but unequal; an epibolic gastrula is formed and the aperture of invagination becomes the permanent mouth of the adult.

**Systematic Arrangement and Mode of Life.**—Order Turbellaria.—Platyhelminths with a ciliated integument, a mouth and pharynx, but no anus; with paired cerebral ganglia and two lateral nerve cords; sexual organs hermaphrodite; chiefly free-swimming.

Sub-order A. *Rhabdocelida*.—Of small size; body cylindrical or depressed; without an intestine, or with a simple unbranched intestine; the female genital glands always compact, not follicular; genital apertures single or distinct.

Tribe I. *Acala* (fig. 1, a).—With a digestive parenchyma not differentiated into intestine and parenchyma proper; with no nervous system or excretory organs; sexual organs hermaphrodite, with follicular testes and paired ovaries: generally without a

pharynx, but having otoliths; all the forms marine. Many quite flat, with the lateral margins bent down towards the ventral surface (*Convoluta*), frequently with brown or green parasitic algae in the parenchyma.

Tribe II. *Rhabdocela* (fig. 1, b).—Intestinal tract and parenchyma separate; nervous system and excretory organs present; with compact testes and female generative glands (ovaries or separated germarium and yolk glands); with a complicated pharynx, but generally without otoliths. Numerous forms, freshwater and marine; the genus *Prorhynchus* (two species) also in damp earth. The *Microstomida* (fig. 9) propagate asexually.

Fig. 9.

FIG. 9.—*Microstoma lineare*, Oc., undergoing division. There are 16 individuals, 8 with mouth apertures, showing the buds of the first ( $m$ ), second ( $m'$ ), third ( $m''$ ), and fourth ( $m'''$ ) generation. The fifth generation has not yet acquired a mouth aperture. c, ciliated g-ovoes; e, eye spots; i, intestine.

Fig. 10.

FIG. 10.—Larva of *Xungia aurantica*, L. (*Polycladida*), with provisional ciliated processes (after A. Lang).

Freshwater forms mostly belong to the families *Mesostomida* and *Vorticida*, some of which contain green parasitic algae. Marine forms include representatives of these two families and of the *Proboscida* (with a tactile proboscis). Of the family *Vorticida*, the genera *Graffia* and *Anoplocladus* are parasitic, the former in Gastropods the latter in Echinoderms (Holothurians).

Tribe III. *Alloioceles* (fig. 1, c).—Intestinal tract and parenchyma separate; nervous system and excretory organs present; with follicular testes and compact female glands (as in the *Rhabdocela*); pharynx similarly developed as a shorter or longer sac. One family (*Monotida*), with otoliths. All the species marine, with one exception, *Plagiostoma lemani*, which lives in the deep water of the Alpine lakes.

Sub-order B. *Dendrocelida*.—Large forms, with a flattened body, branched intestine, follicular testes and follicular yolk glands or ovaries; without otoliths.

Tribe I. *Tricladida*.—Body elongate; intestine with three main branches uniting to open into a cylindrical retractile pharynx; with follicular testes, two round germariums, and numerous yolk follicles, with a single sexual aperture. *Planaria*, *Dendrocelum*, *Polycelis* (fig. 1, g) are inhabitants of fresh water (with great power of reproduction). Terrestrial forms (fig. 1, e, f) of leech-like shape, especially met with in the tropics (only two European species *Rhynchodemus terrestris* and *Geodesmus bilineatus*); marine forms *Gunda* (characterized by a metameric structure), *Bdelloura* (external parasite of *Limulus*).

Tribe II. *Polycladida* (fig. 1, d).—Body leaf-like, thin, and broad, with numerous branched or retiform intestinal coeca which unite to form a central tube (stomach); with follicular testes and follicular ovaries, with two separated genital apertures, the male in front of the female; without (*Acotylea*) or with (*Cotylea*) a sucker situated behind the female generative opening. All marine.

**Literature.**—The most recent works, which also contain a full account of what has gone before, are the following:—*Rhabdocela*.—L. v. Graff, *Monographie der Turbellarien*, 1. *Rhabdocelida*, Leipzig, 1882, with 20 plates. *Marine and Freshwater Tricladida*.—A. Lang, "Der Bau von *Gunda segmentata* und die Verwandtschaft der Platyhelminthen mit Coelenteraten und Hirudineen," in *Mitt. Zool. Stat. Neapel*, vol. III, 1881; El. Metschnikoff, "Die Embryologie von *Planaria polychoa*," in *Zeitschr. f. wiss. Zool.*, vol. xxxviii, 1883; Isao Jijima, "Untersuchungen über den Bau und die Entwicklungsgeschichte der Süßwasser-Dendrocoelen," in *Zeitschr. f. wiss. Zool.*, vol. xl, 1884. *Land Planarians*.—

H. N. Moseley, "On the Anatomy and Histology of the Land Planarians of Ceylon, with some Account of their Habits, and with a Description of Two New Species, and with Notes on the Anatomy of some European Aquatic Species," in *Phil. Trans.* (London, 1874), and "Notes on the Structure of several Forms of Land Planarians, with a Description of Two New Genera and Several New Species, and a List of all Species at present known," in *Quart. Jour. Micro. Sci.*, vol. xiv., 1877; J. v. Kennel, "Die in Deutschland gefundenen Landplanarien *Rhynchodemus terrestris* und *Geodinus bilineatus*," in *Arb. Zool.-Zootom. Instit. Würzburg*, v., 1879. *Polycladida*.—A. Lang, "Die Polycladen," in *Fauna und Flora des Golfes von Neapel*, No. 11, 39 plates, Leipzig, 1884-85. (L. v. G.)

PLANCK, GOTTLIEB JAKOB (1751-1833), theologian and church historian, was born at Nürtingen in Württemberg, where his father was a notary, on November 15, 1751. He was educated for the Protestant ministry at Blaubeuren, Bebenhausen, and Tübingen, and from 1774 to 1784 held successive appointments as repetent, preacher, and professor in Tübingen and Stuttgart. In 1781 he published anonymously the first volume of his *Geschichte des Protestantischen Lehrbegriffs*; the second, also anonymous, appeared in 1783; and in 1784 he was chosen to succeed Walch at Göttingen. Here in the course of a long and useful professional career he enjoyed a large number of academical and ecclesiastical honours. His death took place on August 31, 1833.

The *Geschichte des Protestantischen Lehrbegriffs* was completed in 6 vols. in 1800. It was followed by an extensive *Geschichte der Kirchenverfassung*, in 5 vols. (1803-1809). Both are works of considerable importance, and are characterized by abundant learning and acuteness, the most conspicuous fault in the eyes of his least favourable critics being a tendency, which cannot be wholly denied, to "subjective pragmatism."

PLANTAGENET. This surname, distinctive of a line of kings who ruled in England for more than three hundred years, was first adopted by Geoffrey, count of Anjou, in reference to a sprig of broom (*planta geniste*) which he is said to have worn in his bonnet. He is described by early writers as a very handsome man, but there was certainly nothing very striking in his character. He was the son of Fulk, count of Anjou, king of Jerusalem, who, before his departure for the Holy Land, placed him in possession of the counties of Anjou and Maine. This made him in the eyes of Henry I. of England, who was anxious to protect Normandy, an eligible husband for his widowed daughter, the empress Maud, whom he proposed to make his heiress, both in England and beyond sea. It was a purely political marriage, and the couple immediately afterwards had violent quarrels. Nor was either of them popular in England, where a female sovereign would at that time have been an innovation, and Geoffrey was disliked as a foreigner—although the same objection might have seemed to apply to Stephen of Blois, whose superior activity gained possession of the throne before Maud could make good her pretensions. In a long war with the usurper, though recognized as "lady of England" and virtual sovereign by one part of the country, she was only able in the end to secure the succession for her son. Stephen ended his days in peace, and the house of Plantagenet succeeded to the throne in the person of Henry II. by virtue of a compact.

Henry, the son of Geoffrey of Anjou and the empress Maud, was born at Le Mans in the year 1133, and was just twenty-one years of age when he attained the crown. But his youth had been well spent in preparation for it. When eight years old he was brought to England to be trained in arms. At sixteen he was knighted by his great-uncle David of Scotland. In 1151 his father put him in possession of Normandy, and, dying soon after, left him also the succession to Anjou. These advantages he improved next year by his marriage with Eleanor of Aquitaine, which, by adding Poitou and Guienne to his dominions, gave him the lordship over the whole western side of France from north to south, with the exception of Brittany, which also some time afterwards came under his power.

Having thus, even before he was twenty, become master of so many fair provinces, he then sailed to England, and, though he did not dethrone Stephen, compelled him to acknowledge him as his successor. Next year he was king. It is a new era in the history of England as well as in the fortunes of his house. The country, which was lately so impatient of the rule of a foreigner—fearing, doubtless, that English interests would be sacrificed to those of Anjou—now yields an easy submission to the ruler of all western France from Picardy to the Pyrenees. And, though Henry is in fact one of the greatest of Continental potentates, greater really than his feudal superior the king of France, there is no great cause for anxiety. Henry devotes himself to the interests of his island kingdom, takes steps to secure the succession there to his issue, causing his eldest son even to be crowned king during his own lifetime, and is much more intent on the subjugation of Wales and Ireland and the recognition of his fental superiority over Scotland than upon any extension of his responsibilities abroad. Personally a man of fiery temperament and strong passions, his patience as a politician is remarkable. Bit by bit he is building up a strong empire, and even keeping the pretensions of the church within definite and reasonable bounds. But a single angry word undoes the work of years. He is responsible for Becket's murder. He must do penance and make his peace with the church. He must humiliate himself before Becket's grave.

His dynastic policy seemed almost an equal failure, but was productive of wide and far-reaching consequences. His ungrateful sons rebelled against him, and when he heard that even John had joined the confederacy he felt that he had nothing more to live for. The eldest, Henry, whom he had been so anxious to make a king during his own life, sickened and died in France after flagrant acts of ingratitude and impiety. Geoffrey, to whom he had secured the duchy of Brittany, soon followed his brother; and there remained but Richard and John, besides three daughters, who were all disposed of in marriage to Continental princes. As Richard, though he came to the crown, also died without legitimate issue, the male line was continued in the two sons of John, Henry III. and Richard, king of the Romans, and the issue of the latter became extinct in the next generation.

It is remarkable how the prosperity of England seemed to keep pace with the stability of the succession. The short reigns of Richard I. and John were times of peculiar misery, which was only brought to a climax by the war of the Great Charter and by the dauphin being called in to enforce it. Matters improved under Henry III., even during the minority; but he, too, had a war with his barons in the latter part of his reign. He, too, like his father, had but two sons who grew up to manhood; and, while the elder, Edward I., succeeded him on the throne and was the ancestor of all the following kings, the younger, Edmund Crouchback, became progenitor of the house of Lancaster by the marriage of his great granddaughter Blanche to John of Gaunt, fourth son of Edward III. Edward I. had three sons who came to man's estate; Edward II. only two, or more properly only one, for the second, John of Eltham, died in Scotland at the age of nineteen. Finally the time of Edward III. with his great family was the climax in the fortunes of the house of Plantagenet. Nor need we pursue the family history further, as the story of its descent after the days of Edward III. will be found sufficiently treated elsewhere (see LANCASTER, HOUSE OF, and YORK, HOUSE OF).

Of the alliances of this great dynasty the most important after the days of Henry II. were those of the house of Lancaster. Henry III. married his daughter Margaret to Alexander III. of Scotland, and another daughter to the

duke of Brittany. Edward I. had for his sons-in-law Gilbert de Clare, earl of Gloucester, the duke of Brabant, and the earl of Holland. A daughter of Edward II. married a duke of Gueldres. But "the aspiring blood of Lancaster" spread itself over Europe by alliances with Castile and Portugal, Navarre and Denmark, Bavaria and other foreign states. It has reigned in Portugal to the present day, and it continued to reign in Spain till the end of the 17th century. (J. GA.)

PLANTAIN (Lat. *plantago*), a name given to plants with broad palm-like leaves. This is the case with certain species of *Plantago*, *Alisma*, and *Musa*, to all of which the term is popularly applied. Of the *Plantago* little need be said here, the species being for the most part mere weeds, though one species, *P. lanceolata*, is eaten by cattle, and the seeds of another, *P. major*, are collected for the food of birds. Of far greater general importance is the genus *Musa*, to which belong the Plantain, and the BANANA (*q.v.*). These are gigantic herbs, now diffused by cultivation throughout the tropics of both hemispheres, and sending up from a short thick underground stem shoots with a number of very large leaves whose long, thick leaf-stalks are wrapped one round another. The blades are usually oblong-obtuse, like the blade of an oar, with a very thick midrib from which diverge on each side numerous parallel densely arranged secondary ribs. The flowers are borne in huge pendulous spikes provided with large boat-shaped, often coloured, bracts, in whose axils the whorls of flowers are produced; the lower ones

*Musa sapientum.*

are usually female or hermaphrodite, those at the apex of the spike are male only. These flowers consist of a perianth of six divisions partly united below, slightly two-lipped above, and enclosing five perfect and one imperfect stamen. The ovary is inferior and three-celled—ripening into a long oblong fruit filled with spongy pulp, in which the numerous seeds are embedded. The accumulation of starch and sugar in this pulp renders the fruit of vast importance as an article of diet in the tropics. Corenwinder, cited by Pavy, says that, while starchy matter forms more than 19 per cent. of the ripe fruit—there is also nearly 5 per cent. of nitrogenous matter, about double that of the potato. The plant requires but little attention, and the produce from a relatively small area is enormous; hence it is one of the most valuable of all food-plants. After fruiting, the stem dies down, but provision for new growth is made by the production from the underground stock of numerous offsets. The number of varieties is very great, a circumstance which in itself testifies to the long period during which the plant has been cultivated. It is also the more remarkable in that perfect seeds are comparatively rarely produced, the inference being that the different forms have arisen from bud-variations or "sports." In spite of the vast number of varieties grown in the tropics of both hemispheres—varieties mostly dependent on diversities in the size, form, and flavour of the fruit—the general opinion among botanists is that they have all sprung from one species, the *Musa sapientum* of Brown. Were it otherwise, it is presumed that the varieties found in

America would be different from the Asiatic ones, and these again from those found in the South Sea Islands, &c.; but, as a matter of fact, there are no geographic limitations, the same varieties being found in different quarters of the globe. The varieties are arranged under two heads by Desvieux according to the size of their fruit—the bananas, with fruit 7–15 inches in length, and the fig bananas, with fruit from 1–6 inches long; but these variations are not constant, and Schomburgk has recorded a case in which a spike of the fig banana bore numerous fruits proper to that variety, and in addition a large number of fruits like those of the Chinese dwarf-plantain, *Musa chinensis*, the Cavendish banana of gardens—a case analogous to, but even more remarkable than, the not infrequent occurrence of peaches and nectarines on the same branch. The plantain and the banana are sometimes spoken of as distinct. The former has a green stem and yellow angular fruit not fit for eating till cooked. The banana (*M. sapientum*) has the stem marked with purple spots, and a shorter more cylindric fruit which may be eaten without cooking, but the two run one into the other so that no absolute distinction can be drawn between them. The species have been found in a wild state in Chittagong and Khasia, in the Philippine Islands, in Siam, and in Ceylon, but nowhere truly wild on the American continent.

Throughout tropical and subtropical Asia the plant has numerous and diverse native names; and it was mentioned by old Greek and Latin authors. On the other hand, there are no native names for the plant in Mexico, Peru, or Brazil. From such considerations as these Alphonse de Candolle, in his *Origine des Plantes Cultivées*, sums up the evidence by asserting the Asiatic origin of the plantain and its early introduction into America by the Spaniards or Portuguese. If it should turn out that the banana or the plantain existed in America before the discovery of that continent, then M. de Candolle would attribute that circumstance to some fortuitous introduction at no very remote date rather than to the simultaneous existence of the banana as an indigenous plant in both hemispheres.

It is not only for their fruit that these plants are valuable. The leaves are used for thatching, and the abundant fibre they contain forms a good substitute for hemp. *Musa textilis* is of special value from this point of view. The Abyssinian banana, *M. Ensete*, has dry capsular fruit, and very handsome foliage.

PLANTAIN-EATER. See TOURAKOO.

PLANTIN, CHRISTOPHE (1514–1589), born in a village near Tours (probably Saint-Avertin) in 1514, learned book-binding and book-selling at Caen, and, having married in that town, settled in 1549 as bookbinder in Antwerp, then the principal commercial town of the Netherlands, where he was soon known as the first in his profession. A bad wound in the arm, which unfitted him for this occupation, seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was *La Institutione di una fanciulla nata nobilmente*, by J. M. Bruto, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an heretical pamphlet, which caused his movables to be seized and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business on a larger scale. Among them were two grand-nephews of Dan. Bomberg, who furnished him with the fine Hebrew types

of that renowned Venetian printer. He was now in a position to spare no expense in printing his books with all the care he deemed necessary; and his editions of the Bible in Hebrew, Latin, and Dutch, his *Corpus Juris*, Latin and Greek classics, and many other works produced at this period are renowned for their beautiful execution and accuracy. A much greater enterprise was planned by him in those years—the publication of a *Biblia Polyglotta*, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II. king of Spain, who sent him the learned Benedictus Arias Montanus to take the leading part in the work of editorship. With his zealous help the work was finished in five years (1569–73, 8 vols. fol.). Plantin earned much renown by it, but little profit, or rather less than none; but in compensation he received the privilege of printing all liturgical books for the states of King Philip, and the office of “prototypographus regius,” which carried with it the oversight over all printers in the Netherlands, a charge of which Plantin seems to have acquitted himself indifferently. This need not surprise us, when we know that Plantin, though outwardly a faithful son of the church, was till his death the partisan of a mystical sect of heretics; and it is now proved that many of their books published without the name of a printer came from his presses together with the missals, breviaries, &c., for the Roman Catholic Church.

Besides the polyglott Bible, Plantin published in those years many other works of note, such as editions of St Augustine and St Jerome, the botanical works of Dodonæus, Clusius, and Lobelius, the description of the Netherlands by Guicciardini, &c. In 1575 his printing-office reckoned more than twenty presses and seventy-three workmen, besides a similar number that worked for the office at home. But soon there came bad times for Antwerp. In November 1576 the town was plundered and in part burnt by the Spaniards, and Plantin had to pay an exorbitant ransom. A great many inhabitants of the once flourishing city emigrated, and Plantin also thought of settling elsewhere. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leyden, and invited him to occupy this place, he left his much reduced business in Antwerp to his son-in-law John Moerentorf (Moretus) and Francis van Ravelinghen (Raphelengius), and settled at Leyden. But he could not thrive, it seems, in Holland. When in 1585 Antwerp was taken by the prince of Parma and affairs became there more settled, he left the office in Leyden to Raphelengius and returned to Antwerp, excusing himself for having served the states of the revolted provinces by the difficulties of his situation. In Antwerp he laboured till his death on the 1st July 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note “in officina Plantiniana,” but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left all the old things in the office untouched, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 francs, the authorities were able with little trouble to create one of the most remarkable museums in existence (Musée Plantin, opened 19th August 1877).

PLANTING. See ARBORICULTURE.

PLASENCIA, a city of Spain and an episcopal see, in the north of the province of Caceres (Estremadura), is

pleasantly situated on the right bank of the Xerte or Jerte, a sub-tributary of the Tagus, and at the foot of the sierras of Bejar and Vera, continuations of the Guadarrama range. Industrially and commercially insignificant, the place has some interest for the artist and ecclesiologist on account of its fine walls, built in 1197 by Alphonso VIII. of Castile, and of its cathedral, begun in 1498, which is a favourable specimen of the ornate Gothic of its period, and also shows good examples of the workmanship of Berruguete, Aleman, and other artists. The population of the ayuntamiento was 7090 in 1877. The Hieronymite convent of Yuste, the scene of the last years of the emperor Charles V., lies about 2½ miles to the eastward, and is most conveniently reached from Plasencia.

PLASTER OF PARIS. See GYPSUM.

PLATA, LA. See ARGENTINE REPUBLIC.

PLATA, RIO DE LA. See PLATE RIVER, p. 187.

PLATÆA, or PLATÆE, a celebrated city of ancient Greece, lay at the foot of the northern slope of Mount Cithæron in Bœotia, about 6½ miles by road south of Thebes, or a little over 5 geographical miles in a direct line. Its territory was separated from that of Thebes by the river Asopus. The Thebans claimed to have founded Platæa, but, however this may have been, Platæa was always at feud with its more powerful neighbour. In 519 B.C. the Platæans, being hard pressed by Thebes, applied for help to the Spartan king Cleomenes, who advised them to place themselves under the protection of Athens. They did so, and Athens and Platæa were thenceforward fast friends. It was perhaps on this occasion that the Platæans were granted that restricted citizenship of Athens which we know that they enjoyed at a later time. When Athens faced the Persians alone at Marathon, the Platæans to a man marched out to their help and shared in the victory (490 B.C.). From that day the names of Athens and Platæa were always associated in solemn prayers at Athens. Though dwellers in an inland town, and therefore ignorant of seamanship, the Platæans helped to man the Athenian ships at the sea fight with the Persians off Artemisium (480). In revenge the Persians burned Platæa. The great battle of Platæa, which finally secured the freedom of Greece against the Persians, was fought on the uneven and broken ground to the east and north of the town (September 479). After the battle the Greeks declared the city and territory of Platæa to be independent and inviolable. The Platæans undertook to bring annual offerings of food and raiment to the graves of those who had fallen in the battle; and a festival of liberation (Eleutheria) was celebrated every fifth year. These offerings continued to be brought, and the festival to be held, as late as the 2d century of our era. With the spoils of the Persian wars the Platæans raised a temple of Athene the Warlike.<sup>1</sup> The Peloponnesian War began with an attempt of the Thebans to seize Platæa (431 B.C.). The attempt failed, but in 427, after a siege of about two years, the city was taken by the Peloponnesians and the garrison put to the sword. The bulk of the population had previously taken refuge in Athens. A year afterwards the Thebans razed the city to the ground, and built a large hospice close to the old temple of Hera, to whom they erected a new temple 100 feet long. In 421 the surviving Platæans received from the Athenians the town of Scione in Macedonia as a residence, but they had no doubt to quit it at the end of the war (404). When the peace of Antalcidas was concluded between Greece and Persia (387) Platæa was restored, but a few years afterwards it was surprised and destroyed, except the temples, by the Thebans (about 373). The Platæans were again received

<sup>1</sup> It was built, according to Plutarch (*Arist.* 20), after the battle of Platæa; according to Pausanias (*ix.* 4, 1), after the battle of Marathon.

at Athens, where they were now admitted to full citizenship, except that they were not eligible for the priesthood and the archonship. After the battle of Chæronea (338) Philip of Macedon brought back the Plataeans as a counterpoise to the power of Thebes, but the walls were not fully restored till some years later. Alexander the Great, then monarch of Asia, contributed to rebuild them, in recognition, he declared, of the services which the Plataeans had rendered against the Persians of old. With the loss of Greek freedom Plataea sank into insignificance. The inhabitants lived on the glories of the past, and were regarded as braggarts by the rest of the Boeotians. In the 6th century the walls were once more restored by Justinian.

The fullest description of ancient Plataea is that of Pausanias, who visited it in the 2d century. The great temple of Hera, he tells us, contained a statue of Rhea by Praxiteles; the temple of Athene the Warlike was adorned with an image of the goddess by Phidias and paintings by Polygnotus. Close to the city gates were the tombs of the Greeks who had fallen in the battle of Plataea, and an altar and image of Zeus the Liberator in white marble. The ruins of the ancient town lie about 500 yards east of the modern village of Kokhia. They occupy a slightly elevated plateau forming a rude triangle about two and a half miles in circumference, of which the apex to the south almost touches the great rocky slope of Cithæron, and the base to the north has a steep though short descent to the plain. The outer walls follow the edge of the plateau, but an inner cross-wall divides it into two unequal parts. The southern and higher part is probably as old as the Persian wars; the masonry of the northern part is more recent, and probably belongs to the age of Philip and Alexander. It is likely that these two parts were never included at the same time within the city walls, but that the southern was the ancient city, and that at one of the restorations (perhaps that of 387 B.C.) the northern and more spacious part of the plateau was preferred as the site. Within this northern half, and close to the northern wall, is a terrace on which may have stood the temple of Hera. The north-western corner of the northern town is portioned off by a wall, and is conjectured to have been the acropolis of the newer city.

See Dodwell's *Tour through Greece*, i. p. 274 sq.; Leake's *Travels in Northern Greece*, vol. II. chap. 18; and Bursian's *Geographie von Griechenland*, vol. I. p. 243 sq.

**PLATE.** The word *plate* (connected with the Greek *πλατὺς*, flat, the late Latin *plata* = *lamina*, and the Spanish *plata*, silver) is usually employed to denote works in silver or gold which belong to any class other than those of personal ornaments or coins.<sup>1</sup>

On account of the ease with which it can be worked and the pure state in which it is generally found, it is probable that gold was the first metal used by man; and it is certain that, in some countries at least, he attained to the most marvellous skill in its manipulation at a time when the other arts were in a very elementary condition. As an instance of this we may mention a sword of the bronze age, found in a barrow near Stonehenge, and now in the museum at Devizes.<sup>2</sup> The hilt of this sword is covered with the most microscopically minute gold mosaic. A simple design is formed by fixing tesserae, or rather pins, of red and yellow gold into the wooden core of the handle. Incredible as it may appear, there are more than two thousand of these gold tesserae to the square inch. The use of silver appears to belong to a rather later period, probably because, though a widely spread metal in almost all parts of the world, it is usually found in a less pure state than gold, and requires some skill to smelt and refine it. Though both these precious metals were largely and skilfully used by prehistoric races, they were generally employed as personal ornaments or decorations for weapons. Except in Scandinavian countries but little that can be called "plate" has been discovered in the early barrows of the prehistoric period in western Europe.

<sup>1</sup> In mediæval English the term "a plate" was occasionally used in the sense of a silver vessel. A curious survival of this use of the word still exists at Queen's College, Oxford, where the servants may yet be heard asking at the buttery for so many "plates of beer," that is, silver tankards.

<sup>2</sup> Hoare, *Ancient Wiltshire*, 1840.

It will be convenient to consider the no less prehistoric gold and silver work recently found at Troy, Tiryns, and Mycenæ as forming a stage in the history of Greek art.

**Ancient Egypt.**—An enormous amount of the precious metals was annually brought as tribute to the Egyptian kings; according to Diodorus, who quotes the authority of Hecataeus, the yearly produce of the royal gold and silver mines amounted to thirty-two millions of minæ—that is, about 133 millions sterling of modern money. Though this estimate is probably an exaggeration, the amount must have been very great. The gold chiefly came from the mines in the Bishari desert, about eighteen days' journey south-east of Kum Ombo. These mines were constantly worked down to the time of the Arab caliphs, but now appear to be exhausted. It is not known where the silver came from. Gold appears to have been relatively more abundant than silver, and the difference in value between them was very much less than it is now. Tribute was paid to the Egyptian kings, not in coined money, which was then unknown, but in rings or ingots. Owing to the Egyptian practice of burying with their dead personal ornaments and jewellery, rather than other possessions less intimately connected with the person of the deceased, but few specimens of either gold or silver plate have survived to our times, whereas the amount of gold jewellery that has been discovered is very large, and shows the utmost amount of skill in working the precious metals. We can, however, form some notion of what the larger works, such as plates and vases in gold and silver, were like from the frequent representations of them in mural sculpture and paintings. In many cases they were extremely elaborate and fanciful in shape, formed with the bodies or heads of griffins, horses, and other animals real or imaginary. Others are simple and graceful in outline, enriched with delicate surface ornament of leaves, wave and guilloché patterns, hieroglyphs, or sacred animals. Fig. 1 shows a gold vase of the time of Thothmes III. (Dynasty XVIII., about 1500 B.C.), taken from a wall-painting in one of the tombs at Thebes. The figure on its side is the hieroglyph for "gold." Others appear to have been very large and massive, with human figures in silver or gold supporting a great bowl or crater of the same metal.

FIG. 1.—Gold Vase, from wall-paintings at Thebes.

In the language of the hieroglyphs silver is called "white gold," and gold is the generic name for money,—unlike most languages, in which silver usually has this special meaning,—a fact which points strongly to the priority of the use of gold. On the walls of one of the tombs at Beni Hassan there is an interesting representation of a gold- and silver-smith's workshop, showing the various processes employed—weighing, melting or soldering with the blow-pipe, refining the metal, and polishing the almost finished bowl or vase. In the time of Rameses III., about 1300 B.C., a clearly defined Assyrian influence appears in the decoration of some of the gold plate. A gold basket, represented in the tomb of this king at Thebes, has on its side a relief of the sacred tree between two beasts, the oldest of purely Aryan or Indo-European subjects, and quite foreign to Egypt.

The chief existing specimens of Egyptian plate are five silver *phiale* or bowls, found at the ancient Thumuis in the Delta, and now in the Bulak Museum (Nos. 482 to 486 in the catalogue). These are modelled in the form of a lotus blossom, most graceful in design, but are apparently not earlier than the 5th century B.C. The Louvre possesses a fine gold *patera*, 6½ inches across, with figures of fishes

within a lotus border in repoussé work; an inscription on the rim shows it to have belonged to an officer of Thothmes III. (*Mém. Soc. Ant. de France*, xxiv. 1858).

*Assyrian and Phœnician Plate.*—Among the many treasures of early art found by General Cesnola in the tombs of Cyprus none are of more interest than a large number of Phœnician silver phialæ or saucer-like dishes, enriched with delicate repoussé and tooled reliefs, which in their design present many characteristics of Assyrian art mingled with a more or less strong Egyptian influence. A considerable number of bowls and phialæ found in Assyria itself are so exactly similar to these Cyprian ones, both in shape and ornamentation, that they cannot but be classed together as the production of the same people and the same age. The British Museum possesses a fine collection of these bowls, mostly found in the palace at Nimrud. Though they are made of bronze, and only occasionally ornamented with a few silver studs, they are evidently the production of artists who were accustomed to work in the precious metals, some of them in fact being almost identical in form and design with the silver phialæ found at Curium and elsewhere in Cyprus. They are ornamented in a very delicate and minute manner, partly by incised lines, and partly by the repoussé process, finally completed by chasing. Their designs consist of a central geometrical pattern, with one or more concentric bands round it of figures of gods and men, with various animals and plants. In these bands there is a strange admixture of Assyrian and Egyptian style. The main motives belong to the former class, the principal groups being purely Assyrian—such as the sacred tree between the two attendant beasts, or the king engaged in combat and vanquishing a lion single-handed; while mingled with these are figures and groups purely Egyptian in style, such as the hawk-headed deity, or a king slaying a whole crowd of captives at one blow. Fig. 2 gives a silver dish from

FIG. 2.—Silver Bowl, about 7 inches in diameter, found in a tomb in Cyprus, with repoussé reliefs of Egyptian and Assyrian style

Curium containing examples of all the above mentioned subjects. Some of the designs are exceedingly beautiful, and are arranged with great decorative skill: a favourite composition is that of antelopes walking in a forest of tall papyrus plants, arranged in radiating lines, so as to suit the circular phiale, and yet treated with perfect grace and freedom. In addition to the numerous silver phialæ some were found, with similar decoration, made of pure gold.

The Curium find alone is said to have included more than a thousand objects in gold and silver.

*Etruscan Plate.*—The Etruscan races of Italy were specially renowned for their skill in working all the metals, and above all in their gold work. Large quantities of the most exquisite gold jewellery have been found in Etruscan tombs, including, in addition to smaller objects, sceptres, wreaths of olive, and massive head-pieces. The Museo Kircheriano in Rome possesses a magnificent specimen of the last form of ornament; it is covered with nearly a hundred little statuettes of lions arranged in parallel rows.<sup>1</sup> Little, however, that can be classed under the head of plate has yet been found. A number of silver bowls found in Etruscan tombs have ornaments in the Egypto-Assyrian style, and were probably imported into Italy by the Phœnicians; some almost exactly resemble those found in Cyprus.

The British Museum (gold ornament room) possesses a fine specimen of early plate found at Agrigentum in Sicily. This is a gold phiale or bowl, about 5 inches

FIG. 3.—Ancient Gold Phiale, found at Agrigentum, now in the British Museum. It is shown in section below. It is 5 inches in diameter.

across, with central boss or omphalos (φιάλη μεσόμφαλος) which seems once to have contained a large jewel. Round the inside of the bowl are six figures of oxen, repoussé in relief, and at one side a crescent, formed by punched dots. A delicate twisted moulding surrounds the edge; the workmanship of the whole is very skilful (see fig. 3).

*Hellenic Plate.*—Discoveries made of late years on the plains of Troy, at Mycenæ, and at Camirus in Rhodes have brought to light a large quantity of gold and silver plate of very remote antiquity. These early specimens of plate are all very similar in character, graceful in shape, hammered, cast, and soldered with great skill, but, with the exception of weapons and ornaments, mostly devoid of surface decoration. The most remarkable find was that which Dr Schliemann calls "Priam's treasure," including a large number of silver vases and bowls, with fine massive double-handled cups in gold, and a very curious spherical gold bottle. Fig. 4 shows a silver cup, with gold mounts, found in a tomb at Camirus in Rhodes, apparently a work of the same early date and class. Homer's poems are full of descriptions of rich works in both the precious metals (*Iliad* xxiii. 741), showing that the taste for valuable pieces of plate was developed among the Greeks at a very early time—much more so probably than it was during

<sup>1</sup> Another, very similar, exists in the Vatican Mus. Gregor.

the most flourishing period of Hellenic art, when the production of beautifully painted fictile vases seems to some extent to have superseded the more barbaric magnificence

FIG. 4.—Silver Cantharus from Rhodes, with gold mounts. Possibly the form of the Homeric *δέρας ἀμφικύπελλον*.

of gold and silver. During the 6th century B.C. the demand for works of this class, valuable not only for their material but for their workmanship, seems to have been very great under the last dynasty of Lydian kings, whose wealth in gold and silver has become proverbial. Cræsus especially encouraged the art, and paid enormous sums for silver vases and cups to the most renowned artists of his time, such as Glaucus and Theodorus the Samian.

Pliny (*N. H.*, xxxiii.) gives a valuable account of the sources whence the Greeks and Romans derived their precious metals, their methods of refining, and the sculptors who were most celebrated for their skill in making articles of plate. Among the Greeks and Romans the greatest artists of the day did not disdain to practise this branch of art. The same sculptor who produced noble and colossal statues for the temples of the gods would at another time put forth his utmost skill and artistic talent in chasing and embossing some small silver cup or vase. In this way ancient pieces of plate ranked among the most perfect productions of art—very different from the custom of the 19th century, which leaves its plate to be executed by some dull mechanical craftsman, after the pompous designs supplied by a tradesman whose only standard of merit appears to be the pretentiousness of the design and the number of ounces of silver it contains.

In the best times of Greek art, the chief works in gold and silver seem to have been dedicated to religious purposes, and to have been seldom used for the ostentatious pomp of private individuals. Vessels for the use of the temples, tripods in gold or silver of the richest work, and statues of the gods were the chief objects on which the precious metals were lavished.<sup>1</sup>

The gold used by the Greeks probably came from Asia Minor or Egypt, while the mines of Laurium, in the mountains which form the promontory of Sunium in Attica, supplied an abundant amount of silver for many centuries.<sup>2</sup> According to Pliny, Phidias was the first sculptor who produced works of great merit in the precious metals; he mentions a number of other Greek artists who were celebrated for this class of work, but unluckily does not give their dates. The chief of these were Mentor and Mys (both of the 5th century B.C.), Acragas, Boethus, the sculptors Myron and Stratonicus, as well as the well-known Praxiteles and Scopas. In Pliny's time many works in gold and silver by these artists still existed in Rhodes and elsewhere. Among later workers he specially mentions Zopyrus, who made two silver cups, embossed with the scene of the judgment of Orestes by the Areopagite court, and Pytheas, who made a bowl with reliefs of Ulysses and Diomedes carrying off the Palladium. Enormous prices were given by wealthy Romans for ancient silver plate made by distinguished Greek artists; according to Pliny, more than £300 an ounce was paid for the last-mentioned cup.

<sup>1</sup> The gold eagles on the sacred omphalos at Delphi were notable examples of this; see Pindar, *Pyth.* iv. 4.

<sup>2</sup> Boeckh, *Silver Mines of Laurium*, 1842.

Though a large quantity of later Græco-Roman plate still exists in various museums, the specimens of Greek silver-work of the best period are extremely rare, and mostly unimportant in point of size. In 1812 Dr Lee discovered at Ithaca a very beautiful vase or cyathus  $3\frac{3}{4}$  inches high (see fig. 5) and a phiale or patera,  $9\frac{1}{2}$  inches

FIG. 5.—Silver Crater, found in Ithaca.  $3\frac{3}{4}$  inches high.

across, both of silver, repoussé and chased, with very rich and graceful patterns of leaves and flowers—suggesting a slight tinge of Assyrian style.<sup>3</sup> These are probably not later than the 5th century B.C. A good many silver mirror-cases, with repoussé figure-subjects in high relief, have been found at various places; as, for instance, one

with a beautiful seated figure of Aphrodite found at Tarentum and now in the British Museum.<sup>4</sup> The South Kensington Museum contains a most exquisite little silver vase found in the baths of Apollo at Vicarello in Italy (fig. 6), enriched with a band in low relief of storks devouring serpents, executed with gem-like minuteness and finish—probably not later than the 3rd century B.C. The British Museum has a little vase of similar form and almost equal beauty, though perhaps later in date; it is decorated with bands of vine branches in a graceful flowing pattern, and is partly gilt. The most important

FIG. 6.—Greek Silver Vase, 5 inches high, c. 4th century B.C. The ornamental band is shown below in plano. (South Kensington Museum.)

find of Greek silver plate, mingled with pieces of Roman or Græco-Roman work, was that discovered in the crypt of the temple of Mercury Augustus, at Villeret, near Bernay, in France (the ancient Canetum), in 1830.<sup>5</sup> It

<sup>3</sup> See *Archæologia*, xxxiii. 36-54.

<sup>4</sup> *Ib.*, xxxiv. 265-72.

<sup>5</sup> See Chabouillet, *Catalogue des Camées, &c., de la Bibliothèque Impériale*, Paris, 1858, pp. 418-57; also Raoul Rochette, *Monuments d'Antiquité*, p. 272, and Lenormant, *Bull. dell' Inst. Arch.* Rome, 1830.

consists of silver vessels and two silver statuettes, sixty-nine pieces in all, the gift of various donors to the temple. It is in itself a small museum of specimens of ancient plate, containing objects of great variety of date and workmanship, from fine Greek work of about 300 B.C. down to the coarser Roman production of the 2nd or 3rd century A.D. The shapes of the vessels composing this treasure are very numerous—ewers, bowls, patera, large ladle-shaped cups, and drinking cups with and without handles. Those of Greek workmanship are in slight relief, while some of the Roman wine-cups and bowls have heads and figures almost detached from the ground. Some of these latter much resemble some silver canthari found in Pompeii.<sup>1</sup> The dedicatory Roman inscriptions, in some cases, appear to be later additions, made by the various donors who presented these treasures to the temple.<sup>2</sup> It is interesting to note that two vases among the Bernay treasure have reliefs of the theft of the Palladium, like the celebrated cup by Pytheas mentioned by Pliny; another subject described by him as decorating silver plate by Zopyrus, the judgment of Orestes, is represented on a fine cup found at Antium, apparently of Greek design, which is preserved in the Corsini Palace in Rome. These may possibly be copies from originals by those much-renowned artists.

*Græco-Roman and Roman Plate.*—Of what may be called Græco-Roman plate a much larger number of specimens still exist. Even during the 1st century the growing pomp and ostentation of the wealthy Romans led to an enormous demand for large and elaborate pieces of plate, while their good taste induced them to prefer the works of Greek *calatores*,—a branch of art which even at that time showed but little signs of decay. It was no doubt the desire for objects which should combine intrinsic value with artistic merit, and also be of a more durable sort, that by slow degrees gave the death-blow to the art of vase painting. It is not always easy to distinguish the best works in silver of this Roman period from the more purely Greek works of an earlier time. They are often of the highest merit both in design and execution. The finest collection of these was found in 1369 at Hildesheim in Hanover, and is now in the Berlin Museum. They consist of a large number of cups, bowls, vases, dishes, and tripods, all of silver, some decorated with gilding and enriched in the most elaborate way with figure and scroll-work reliefs of the greatest beauty and finish; these, except one or two of very rude work, can hardly be later in date than the first century after Christ. The most remarkable is a cylix, inside which a geometrical Greek border in slight relief forms a frame for a seated figure of Athene—an “*emblema*” soldered on, in very high relief. The attitude of this figure, the folds of the drapery, and other details are arranged with extreme grace. Almost the only point which recalls the fact that this exquisite piece does not belong to the best period of Greek art is the very salient relief of the figure, whereas in earlier times the silver-worker was content with a more moderate amount of relief, and thus decorated the surface of his vessel without injuring its main contour. A large silver crater in the same set (fig. 7) is free from this fault. It is covered outside with delicate floral scroll-work, growing in graceful curves all over the surface of the vessel, with very slight projection from the main surface,—a perfect model in every way for the treatment of silver. Pliny specially mentions the custom of Roman generals and other officers travelling on military

expeditions with magnificent services of plate; and it appears probable that this had been the case with the

FIG. 7.—Silver Crater, 15½ inches high, from the Hildesheim set. (Berlin Museum.)

Hildesheim treasure; defeat or some other disaster may have forced the Roman owner to hide and relinquish the whole set.<sup>3</sup>

The museum at Naples contains a very large number of silver cups found in Pompeii, encrusted with figure-subjects or branches of ivy and vine in relief. In cases of this sort the cup is made double, with a smooth inner skin to hide the sinkings produced by the repoussé work in relief on the outside. Silver vessels ornamented in relief were called by the Romans *calata* or *aspera*, to distinguish them from plain ones, which were called *levia*.<sup>4</sup>

Among later specimens of Roman plate the most remarkable is the gold patera, nearly 10 inches in diameter, found at Rennes in 1777, and now in the Paris Bibliothèque—a work of the most marvellous delicacy and high finish—almost gem-like in its minuteness of detail. Though not earlier than about 210 A.D., a slight clumsiness in the proportion of its embossed figures is the only visible sign of decadence. The outer rim is set with sixteen fine gold coins—*aurei* of various members of the Antonine family from Hadrian to Geta. The central *emblemata* or medallion represents the drinking contest between Bacchus and Hercules, and round this medallion is a band of repoussé figures showing the triumphal procession of Bacchus after winning the contest. He sits triumphant in his leopard-drawn car, while Hercules is led along, helplessly intoxicated, supported by bacchanals. A long line of nymphs, fauns, and satyrs complete the circular band.

The so-called “shield of Scipio,” also in the Paris Bibliothèque, which was found in the Rhone near Avignon, is the finest example of Roman plate of the 4th century. It is not a shield, but a large silver patera, about 26 inches in diameter, with a repoussé relief representing the restoration of Briseis to Achilles. The composition and general design are good, but the execution is feeble and rather coarse.

<sup>3</sup> Darcel, *Trésor de Hildesheim*, 1870. The number of gold and silver statues in Rome was very great. In the inscription of Ancyra, Augustus records that he melted down no less than 80 silver statues of himself, and with the money thus obtained presented “golden gifts” to the temple of Apollo Palatinus. See *Mon. Ancyra*, ed. Mommsen, 1883.

<sup>4</sup> For the various classical methods of working in silver and gold see METAL-WORK.

<sup>1</sup> Quaranta, *Quattordici Vasi d'Argento . . . Pompei*, Naples, 1837.

<sup>2</sup> See a valuable paper on this subject in the *Journal of Hellenic Studies*, vol. iii.—No. 1, by Dr Waldstein, who attributes part of this treasure to the Ephesian school of artists, and traces in some of the designs miniature reproductions of large works of Greek sculpture.

The British Museum possesses good specimens of Roman silver work in its last stage of decline. These are two large caskets or toilet boxes, with silver unguent vases, oblong *lances*, pateræ, ewers, spoons, and other objects, all found in Rome in 1793. The caskets are decorated in low relief with somewhat blunt repoussé figures and ornaments. The rim of one casket is incised with the following words—*SECUNDE ET PROECTA VIVATIS IN CHRISTO*. One of the silver vases has the words *PELEGRINA VTERE FELIX*. The legend on the casket, and the ☩ which appears among the ornaments, show that it was made for a Roman lady, named Projecta, who was a Christian; her portrait, together with that of her husband Secundus, is on the centre of the lid in a medallion supported by two cupids. With the exception of a pair of small silver two-handled vases, undecorated, but of the purest Greek-like form, these various pieces of silver work probably date from the 5th century.<sup>1</sup>

*Plate from the Crimea.*—The finest collection of early gold and silver plate is that in the Musée de l'Ermitage at St Petersburg, the result of many years' excavation in the tombs of the Cimmerian Bosphorus.<sup>2</sup> Most of these magnificent pieces of plate, both in style of workmanship and the character of their decoration, resemble the work of Greek artists; in some cases nothing but the costume of the figures embossed upon them shows that they were not produced in Athens.

The earliest in style is a massive gold phiale (φιάλη μεσάμφαλος) covered with the richest and most minute surface ornament. The motive of the design is taken from an open lotus flower; the petals form radiating lobes, and these petals are entirely covered with delicate scroll-work, surrounding Greek-like gorgons' heads, and other smaller heads, savage-looking and bearded. Though perhaps rather overloaded with ornament, this beautiful phiale, which shows strong traces of Phœnician or Assyrian influence, is a real masterpiece of decorative design. Of later date, probably 4th century *n.c.*, is a small gold bottle, Hellenic in form, but ornamented with a band of non-Hellenic figures in relief—Scythian bowmen, as their dress clearly shows. The grandest piece of all is a large silver amphora, of about the same date, shaped like the Greek fictile amphora, and ornamented with a beautiful flowing pattern, of pure Hellenic honeysuckle form, mingled with birds and very highly projecting animals' heads. On the shoulder of the vase there is a band of Scythians and horses, executed with great spirit and refinement.<sup>3</sup> It is difficult to believe that this splendid vase, so graceful in outline, and so pure in its decoration, was not produced by some famous Athenian *toreutes*.

*Oriental Plate.*—Some very curious pieces of plate both in gold and silver have been found in northern India; these appear to be of native workmanship, but the subjects with which they are embossed, and the modelling of the figures, show that they were produced under late Roman influence, or in some cases possibly even Greek influence in a highly degraded state, handed down from the time of Alexander's Indian conquests.

Under the Sasanian kings of Persia (from the 3rd to 6th centuries) very massive and richly decorated gold vases, bowls, and bottles were made (fig. 8). Those which still exist show a curious mingling of ancient Assyrian art with that of Rome in its decline. Reliefs representing winged lions, or the sacred tree between its attendant beasts, alternate with subjects from Roman mythology,

such as the rape of Ganymede; but all are treated alike with much originality, and in a highly decorative manner. The Paris Bibliothèque and the Vienna Museum contain some fine specimens.

The gold and silver work of Russia resembles in style that of Byzantium at an early period. Shrines and other magnificent pieces of plate in the treasury of the cathedral at Moscow (see Weltmann, *Le trésor de Moscou*, 1861), though executed at the end of the 15th century, are exactly similar in design to Byzantine work of the 11th or 12th century, and even since then but little change or development of style has taken place.

The caliphs of Baghdad, the sultans of Egypt, and other Moslem rulers were once famed for their rich stores of plate, which was probably of extreme beauty both in design and workmanship. Little or nothing of this Moslem plate now remains, and it is only possible to judge of its style and magnificence from the fine works in brass and other less valuable metals which have survived to our time.

*Early Mediæval Plate.*—The Gothic, Gaulish, and other semi-barbarian peoples, who in the 6th century were

Fig. 8.

FIG. 8.—Sasanian Gold Bottle, about 10 inches high. In the Vienna Museum.

Fig. 9.

FIG. 9.—Gold Ewer, 15 inches high, from the Petrossa treasure.

masters of Spain, France, and parts of central Europe, produced great quantities of work in the precious metals, especially gold, often of great magnificence of design and not without some skill in workmanship. In 1837 a large number of pieces of very massive gold plate were found at Petrossa in Roumania; much of this find was unfortunately broken up and melted, but a considerable portion was saved, and is now in the museum at Bucharest. These magnificent objects are all of solid gold, and consist of large dishes, vases, ewers, baskets of open work, and personal ornaments (fig. 9). Some of them show a strong Roman influence in their design, others are more purely barbaric in style. To the first of these classes belongs a very fine phiale or patera, 10 inches in diameter. In the centre is a seated statuette of a goddess, holding a cup, while all round, in high relief, are standing figures of various male and female deities, purely Roman in style. Though the execution is somewhat clumsy, there is much reminiscence of classical grace in the attitudes and drapery of these figures. A large basket and other pieces, made of square bars of gold arranged so as to form an open pattern of stiff geometrical design, have nothing in common with the vessels in which Roman influence is

<sup>3</sup> *Gaz. des B. Arts*, xxv. 19–39, 1832.

apparent, and can hardly be the work of the same school of goldsmiths.<sup>1</sup> The date of this Petrossa treasure is supposed to be the 6th century. The celebrated Gourdon gold cup and tray now preserved in Paris belong to about the same date. They are very rich and magnificent, quite free from any survival of classic influence, and in style resemble the Merovingian gold work which was found in the tomb of Childeric I. The cup is three inches high, shaped like a miniature two-handled chalice; its companion oblong tray or plate has a large cross in high relief in the centre. They are elaborately ornamented with inlaid work of turquoises and garnets, and delicate filigree patterns in gold, soldered on.

In the 6th century Byzantium was the chief centre for the production of large and magnificent works in the precious metals. The religious fervour and the great wealth of Justinian and his successors filled the churches of Byzantium, not only with enormous quantities of gold and silver chalices, shrines, and other smaller pieces of ecclesiastical plate, but even large altars, with tall pillared baldacchini over them, fonts, massive candelabra, statues, and high screens, all made of the precious metals. The wealth and artistic splendour with which St Peter's in Rome and St Sophia in Constantinople were enriched is now almost inconceivable. To read the mere inventories of these treasures dazzles the imagination,—such as that given in the *Liber Pontificalis* of Anastasius Bibliothecarius, which includes the long list of treasures given by Constantine to St Peter's before he transferred his seat of empire to Byzantium (330), and the scarcely less wonderful list of gold and silver plate presented to the same basilica by Pope Symmachus (498–514).<sup>2</sup>

During the 7th century France and other Western countries were but little behind Italy and Byzantium in their production of massive works, both secular and religious, in the precious metals. St Eloy, the French goldsmith bishop, made a number of most splendid shrines and other sacred furniture in beaten gold—among them large shrines for the relics of St Denis, St Geneviève, and St Martin, as well as gold thrones, plate, and jewellery for the French kings Clothaire II and Dagobert I. At this time every cathedral or abbey church in Germany, France, and even England began to accumulate rich treasures of every kind in gold and silver, enriched with jewels and enamel; but few specimens, however, still exist of the work of this early period. The most notable are Charlemagne's regalia<sup>3</sup> and other treasures at Aix-la-Chapelle, a few preserved at St Peter's in Rome, and the remarkable set of ecclesiastical utensils which still exist in the cathedral of Monza near Milan—the gift of Queen Theodelinda in the early part of the 7th century.<sup>4</sup>

The existing examples of magnificent early work in the precious metals mostly belong to a somewhat later period. The chief are the gold and silver altar in Sant' Ambrogio at Milan, of the 9th century; the "Pala d'Oro," or gold retable, in St Mark's at Venice, begun in the 10th century (see METAL-WORK); and the gold altar frontal given by the emperor Henry II and his wife Cunigunde, at the beginning of the 11th century, to the cathedral at Basel. The last is about 4 feet high by 6 feet long, repoussé in high relief, with figures of Christ, the three archangels, and St Benedict, standing under an arcade of round arches; it is now in the Cluny Museum in Paris.<sup>5</sup> A similar gold frontal, of equal splendour, was that made for the archbishop of Sens in 999. This was melted down by Louis

XV. in 1760, but fortunately a drawing of it was preserved, and is published by Du Sommerard (*Album*, 9th series, pl. xiii.).

A most valuable description of the various methods of work practised by gold- and silver-smiths in the 11th and 12th centuries is given by the monk Theophilus in his *Diversarum Artium Schedula* (Hendrie's ed., 1847). He minutely describes every possible process that could be employed in making and ornamenting elaborate pieces of ecclesiastical plate—such as smelting, refining, hammering, chasing and repoussé work, soldering, casting (by the "cire perdue" process), wire-drawing, gilding with mercury amalgam, and the application of niello, enamel, and gems.

The silversmith of those days, as in classical times, was not only a thorough artist with a complete sense of beauty and fitness in his work, but he was also a craftsman of the most varied fertility of resource, and made himself thoroughly responsible for every part of his work and every stage through which it passed,—a most striking contrast to the modern subdivision of labour, and eagerness to produce a show of neatness without regard to real excellence of work, which is the curse of all 19th-century handicrafts, and one of the main reasons why our modern productions are in the main neither works of true art nor objects of real lasting utility.

*Italian Plate.*—Before the latter part of the 15th century, large pieces of silver work were made more for ecclesiastical use than for the gratification of private luxury. The great silver shrine in Orvieto cathedral, made to contain the blood-stained corporal of the famous Bolsena miracle, is one of the chief of these. It is a very large and elaborate work in solid silver, made to imitate the west front of a cathedral, and decorated in the most sumptuous way with figures cast and chased in relief, and a wonderful series of miniature-like pictures embossed in low relief and covered with translucent enamels of various brilliant colours. This splendid piece of silver work was executed about 1338 by Ugolino da Siena and his pupils. The other most important pieces of silver work in Italy are the frontal and retable of St James in the cathedral at Pistoia, and the altar of San Giovanni at Florence (see METAL-WORK). On these two works were employed a whole series of the chief Tuscan artists of the 14th and 15th centuries, many of whom, though of great reputation in other branches of art, such as painting, sculpture on a large scale, and architecture, did not disdain to devote their utmost skill, and years of labour, to work which we now as a rule consign to craftsmen of the very smallest capacity.

Among the distinguished names of Florentines who during the space of one century only, the 15th, worked in gold and silver, the following may be given to suggest the high rank which this class of work took among the arts:—Brunelleschi, Ghiberti, Donatello, Luca della Robbia, the two Pollaiuoli, Verrocchio, Michelozzo, Ghirlandaio, Botticelli, Lorenzo di Credi, Baccio Baldini, and Francia. The cities of Italy which chiefly excelled in this religious and beautiful class of silver-work during the 14th and 15th centuries were Florence, Siena, Arezzo, Pisa, and Pistoia.

Owing to the demoralization and increase of luxury which grew in Italy with such startling rapidity during the early years of the 16th century, the wealth and artistic skill which in the previous centuries had been mainly devoted to religious objects were diverted into a different channel, and became for the most part absorbed in the production of magnificent pieces of plate—vases, ewers, dishes, and the like—of large size, and decorated in the most lavish way with the fanciful and over-luxuriant forms of ornament introduced by the already declining taste of the Renaissance. This demand created a new school of metal-workers, among whom Benvenuto Cellini

<sup>1</sup> Soden Smith. *Treasure of Petrossa*, 1869.

<sup>5</sup> *Archæologia*, xxx. 144–48.

(1500-1571) was perhaps the ablest, and certainly the most prominent. His graphic and often shameless autobiography makes him one of the foremost and most vivid figures of this wonderful 16th century, in which the most bestial self-indulgence was mingled with the keenest enthusiasm for art. Cellini's work is always perfect in execution, but very unequal in merit of design; some of his silver pieces, such as the large salt-cellar made for Francis I., are much marred by an attempt to produce a massive grandeur of effect, on a scale and in a material quite unsuited to such ambitious and sculptural effects. Cellini's influence on the design of silver plate was very great, not only in Italy and France, where his life was spent, but also on the great silversmiths of Augsburg and Nuremberg, many of whose finest pieces are often attributed to Cellini.<sup>1</sup> During the 17th and even the 18th centuries fine pieces of plate were produced in Italy, many of them still retaining some of the grace and refinement of the earlier Renaissance.

*Germany.*—From very early times Germany was specially famed for its works in the precious metals, mostly, as in other countries, for ecclesiastical use.

In the 15th century a large quantity of secular plate was produced, of very beautiful design and the most skilful workmanship. Tall covered cups or hanaps on slender stems, modelled with a series of bosses something like a pineapple and surmounted by a cleverly wrought flower, or beakers, cylindrical tankards with lids, enriched with delicate Gothic cresting or applied foliage, are the most beautiful in form and decoration. On the lids of these cups are frequently placed heraldic figures, holding shields with the

FIG. 10.—Silver Beaker, decorated with open work, filled in with translucent enamels. German or Flemish, of the 15th century. (S. K. M.)

owner's arms, modelled and cast with great spirit and finish. One celebrated silver beaker, of about 1400, now in the South Kensington Museum (fig. 10), is ornamented with Gothic tracery windows filled in with translucent enamels.<sup>2</sup> Another,<sup>3</sup> rather later in date, preserved in the print room of the British Museum, is covered with figures and foliage in minute niello work, a most elaborate and splendid piece of plate.

During the first half of the 16th century Augsburg and Nuremberg, long celebrated for their silver work, developed a school of artists in plate whose productions are of the most unrivalled beauty, at once graceful in general form and decorated in slight relief with arabesques, strap-work, wreaths, and figure subjects arranged with the utmost good taste, and modelled and chased with the most perfect precision of touch. Though influenced by the contemporary silver-work of Italy, the works of Paul Flint, Wenzel

Jamnitzer (1508-1585), and Theodor de Bry of Liège (1528-98) are free from the extravagance of outline and over-elaboration of detail which often disfigure the grand silver pieces of men like Cellini (see fig. 11). In Germany the traditions of earlier Gothic art were less rapidly broken with; and many purely Gothic forms survived there till quite the end of the 16th century. In the first half of the 17th century the technical skill of the German silversmiths reached its highest point of perfection, but there was some falling off in their designs, which rapidly lost their purity of outline. Switzerland produced several silversmiths whose work is similar to that of this German school, especially their large plateaux and ewers, most richly and gracefully covered with ornament, all finished with almost gem-like minuteness. The principal among these artists was François Briot, all of whose productions are of extreme beauty. The majority of his existing works are not in silver, but in pewter, and thus by their absence of intrinsic value have escaped the melting pot (fig. 12). Gaspar Enderlein was another workman of this school, whose productions cannot always be distinguished from those of Briot. Though born in Switzerland, these artists really belong to the great Augsburg and Nuremberg school.

FIG. 11.—Silver Cup, 8½ inches high, usually attributed to Jamnitzer, but more probably by Paul Flint. Made at Nuremberg about the middle of the 16th century. (S. K. M.)

Many of the famous 15th and 16th century painters, such as Martin Schön, Israel von Mecken, and Holbein, used to supply the silver-workers with elaborate designs for plate. Virgil Solis of Nuremberg (1514-1562) was especially fertile in this sort of invention, and executed a large series of etchings of designs for vases, cups, ewers, tazze, and all sorts of plate.<sup>4</sup>

*Spain.*—Throughout the Middle Ages Spain was remarkable for its large and magnificent works in the precious metals. The cathedral of Gerona still possesses a most massive silver retable, made by a Valencian silversmith called Peter Bernec. The gold and silver altar-

frontal, a work of the 11th century, was carried off from this cathedral by the French in the present century. Another very large and beautiful piece of silver work is the throne, Northern Gothic in style, made for King Martin of Aragon, about 1400, and now preserved in Barcelona cathedral. Till after 1500 little that is distinctively Spanish appears in the style of their silver work. At first Moorish influence, and then that of France and Germany, appear to have been paramount. It is not till the 16th century that a really Spanish school of art was developed; and the discovery of America with its rich stores of gold and silver gave an enormous impetus to this class of work.<sup>1</sup> The "custodia," or tabernacle for the host, in many of the Spanish cathedrals, is a large and massive object, decorated in a very gorgeous though somewhat debased style. In spite of the plundering of the French, even now no country is so rich in ecclesiastical plate as Spain.

*England.*—The Celtic races of both England and Ireland appear to have possessed great wealth in gold and silver, but especially the former. It seems, however, to have been mostly used in the manufacture of personal ornaments, such as torques, fibulae, and the like. A magnificent suit of gold armour, repoussé with simple patterns of lines and dots, was found some years ago at Mold in Flintshire, and is now in the British Museum.<sup>2</sup> The amount of gold jewellery found in Ireland during the past century has been enormous; but, owing to the unfortunate law of "treasure-trove," by far the greater part was immediately melted down by the finders. Little of this period that can be called plate has been discovered in the British Isles,—unlike Denmark and other Scandinavian countries, where the excavation of tombs has in many cases yielded rich results in the way of massive cups, bowls, ladles, and horns of solid gold, mostly decorated with simple designs of spirals, concentric circles, or interlaced grotesques. Others are of silver, parcel-gilt, and some have figure subjects in low relief (fig. 13). In like manner, during the Saxon

period, though gold and silver jewellery was common, yet little plate appears to have been made, with the exception of shrines, altar-frontals, and vessels for ecclesiastical use, of which every important church in England must have possessed a magnificent stock. With regard to English secular plate, though but few early examples still exist, we know from various records, such as wills and inventories, that the 14th century was one in which every rich lord

or burgher prided himself on his fine and massive collection of silver vessels; on festive occasions this was displayed, not only on the dinner-table, but also on sideboards, arranged with tiers of steps, one above the other, so as to show off to advantage the weighty silver vases, flagons, and dishes with which it was loaded. The central object on every rich man's table was the "nef"—a large silver casket, usually (as the name suggests) in the form of a ship, and arranged to contain the host's napkin, goblet, spoon, and knife, with an assortment of spices and salt. Great sums were often spent on this large and elaborate piece of plate, e.g., one made for the duke of Anjou in the 14th century weighed

<sup>1</sup> See Rialto, *Industrial Arts in Spain*, 1879; and Davillier, *L'orfèvrerie en Espagne*, 1879.

<sup>2</sup> *Archæol.*, xvi. 422.

348 marks of gold. The English silversmiths of this period were highly skilled in their art, and produced objects of great beauty both in design and workmanship. One of the finest specimens of late 14th century plate which still exists is a silver cup belonging to the mayor and corporation of King's Lynn. It is graceful and chalice-like in form, skilfully chased, and decorated in a very rich and elaborate way with coloured translucent enamels (fig. 14) of ladies and youths, several with hawks on their wrists.<sup>3</sup> Silver salt-cellars were among the most elaborate pieces of plate produced

Fig. 14.

Fig. 14.—Silver Cup, with translucent enamels. Probably French work of the 14th century.

Fig. 15.

during the 15th century. Several colleges at Oxford and Cambridge still possess fine specimens of these (fig. 15); the favourite shape was a kind of hour-glass form richly ornamented with spiral fluting or bosses.

But few existing specimens of English plate are older than the beginning of the 15th century. Among the few that remain the principal are two or three chalices—such as the two large gold ones found in the coffin of an archbishop of York, now used for holy communion in the cathedral, and a fine silver chalice from the church of Berwick St James, Wilts, now in the British Museum. Both this and the York chalices are devoid of ornament, but, judging from their shape, appear to be of the 12th or 13th century.<sup>4</sup>

It is interesting to note the various changes of form through which the ecclesiastical chalice passed from early Christian times till the 16th century. It was at first an ordinary secular cup (fig. 16, A), with two handles classical in form, and of large capacity, because the laity as well as the clergy received the wine. The double handles were of practical use in passing the cup round like a modern "loving cup." The first alteration was the omission of the handles, so that it took the form B, with large hemispherical bowl, a round foot, and a knop for security in holding it. For some centuries it appears to have been the custom for the priest to hold the chalice, while the communicant sucked the wine through a silver tube or "fistula." Some of the most magnificent

<sup>3</sup> See Carter, *Specimens of Ancient Sculpture*, &c., 1838.

<sup>4</sup> Among the most important existing specimens are the solid gold chalice and paten preserved at Corpus Christi College, Oxford, the gift of the founder, Bishop Fox. These have the year-mark K for 1507–8. See *Quart. Rev.*, cxi. p. 353.

early examples of this form of chalice have the bowl mounted in bands, set with jewels, and enriched with minute filigree work,—a design which appears to have been taken from those cups, such as the four magnificent examples in the treasury of St Mark's at Venice, which have their bowl cut out of crystal, onyx, or some other precious stone.<sup>1</sup> The finest examples of this class are the Ardagh chalice, now in the Dublin Museum, and the chalice of St Remigius, in Rheims cathedral; both are most magnificent specimens of the taste and skill of 11th-century goldsmiths. C shows the next form (12th and 13th centuries). The design is simpler; there is a distinct shaft, extending above and below the knop; and on the foot is marked a cross, not found in the earlier ones, to show which side the priest is to hold towards himself at celebration. The next alteration in the form of chalice,

FIG. 16.—Various shapes of Chalices, showing development from the earliest form.

which occurred in the 14th century, was to make the foot not circular in plan but polygonal or lobed, so that the cup might not roll when laid on its side to drain, after it had been rinsed out. It thus took the shape D, and this form lasted in most countries till about 1500, and in England till the Reformation. In countries which did not adopt the Reformed faith the shape was altered, by the general growth of the Renaissance, into a form frequently like E. But in England the change was more complete; the bowl, which in the previous two or three centuries had been slowly reduced in size, owing to the gradually introduced practice of refusing the wine to the laity, was suddenly made more capacious, and the form was altered to the shape F, in order that the Protestant "communion cup" might bear no resemblance to the old Catholic "massing chalice." This was ordered to be done in 1562, (see *Arch. Jour.* xxv. 44-53). The last form, G, shows the usual shape of sepulchral chalices, which, before the Reformation, were enclosed in the coffins of all ecclesiastics who had received priest's orders. These are without the knop, and were frequently made of pewter, tin, or even wax, as they were not meant for use. In some few cases a real chalice was buried with some ecclesiastic of rank, but this was exceptional.

Secular plate during the 15th and 16th centuries was very similar in style to that made in Germany, though the English silversmiths of the latter century never quite equalled the skill or artistic talent of the great Nuremberg and Augsburg silver-workers. In the 17th century, during the reigns of James I. and Charles I., many fine pieces of plate, especially tall hanaps and tankards, were made of very graceful form and decoration. The greater part of this, and all earlier plate, especially the fine collections belonging to the universities, were melted down during the Civil War. In Charles II.'s reign, however, prosperity and the king's own work, *De l'Orfèvrerie*, 1668, the production of *Arts of the Middle Ages*, 1851.

<sup>1</sup> See De Fleury, *Decorations of the Middle Ages*, 1858.

on a large scale, such as toilet services, wine-coolers, and even fire-dogs and tables. These are very florid in their ornament, and mostly have lost the beautiful forms of the century before (fig. 17). In the early part of the

FIG. 17.—Covered Cup of solid gold, 6 inches high, circa 1660-70. Given to Exeter College, Oxford, by George Hall, Bishop of Chester.

18th century the designs are mostly poor, and the decoration rather coarse, till the time of the classical revival which was brought about mainly by the discovery of the buried cities of Pompeii and Herculaneum. A quite different style of plate then came into vogue—semi-classical both in form and decoration, and often worked with great delicacy of treatment. A good deal of plate in this style was made under the influence of the brothers Adam (fig. 18), distinguished architects in the second half of the 18th century. Of modern plate from the art point of view there is nothing to say; it is nearly always poor in design and feeble in execution.

*The Assay of Gold and Silver Plate.*—The primitive method of testing the purity of the metal was by marking a streak with it on the touch-stone, and comparing the colour of the mark with that made by various pieces of gold or silver of known degrees of purity. Assay by cupellation is now employed for silver: a piece of the silver to be tested is melted with some lead in a cupel or bone-ash crucible; the lead is oxidized, and rapidly sinks into the bone-ash, carrying with it any other impurities which are present. The residue of pure silver is then weighed, and by its loss shows how much alloy it contained. Gold is now tested by an elaborate chemical process by which the trial bit is dissolved in acid, and then thrown down in the form of precipitate, which can be examined by a careful quantitative analysis. See ASSAYING, GOLD, and SILVER.

FIG. 18.—Silver Vase, 11 inches high, dated 1772. Designed by the brothers Adam. (S. R. M.)

The standard of purity required in the time of Edward I. was, for gold, that it should be of the "Paris touch," i.e., 19½ carats out of 24. Before then 22 carats was the standard. Silver was to be "of the sterling alloy," viz., 11 oz. 2 dwts. to the pound. Except for a time during the 16th century, this standard of silver has been kept up, and is still required by law.

*Hall-marks on Silver.*—In the 13th century the English Guild of Gold- and Silver-smiths had grown into great importance, and had acquired monopolies and many special privileges. In order to keep the standard up to the required purity the system of requiring each article to be stamped with certain marks was introduced by royal command. The first of these was the *King's mark*—a leopard's or lion's head crowned. This was introduced in 1300 by Edward I. (29 Edw. I. stat. 3, c. 30). The second, the *Maker's mark*, was added in 1363 (37 Edw. III. c. 7). This might be any badge or initial chosen by the master silversmith himself. The third was the *Year letter* or *Assayer's mark*; this was an alphabet, one letter being used for a year, counting from the day of the annual election of the warden of the Goldsmiths' Company. When one alphabet was exhausted, another with differently-shaped letters was begun. The first of these series of year-letters commences in 1438. The earliest existing piece of plate which has the three marks

complete is a spoon which was given by Henry VI. to Sir Ralph Puiſey; this has the year mark for 1445. Other marks, ſubſe-  
quently introduced, were the lion paſſant, firſt uſed in 1545; the  
lion's head eras'd, and a full-length figure of Britannia, uſed only  
between 1697 and 1720; and laſtly the portrait of the reigning  
ſovereign, which has been in uſe ſince 1784. In addition to theſe  
general hall marks, the place made in various towns had from the  
year 1423 certain ſpecial provincial marks. The beſt work on  
hall-marked plate and the marks themſelves, with the hiſtory of  
the Silversmiths' Company, is Cripps, *Old Engliſh Plate*, 1831.  
See alſo Cripps, *Old French Plate*, 1850.

The South Kensington Museum has a very fine illustrative collection of plate, from early mediæval times downwards. It also possesses a very valuable and large assortment of electrotypes copies, including the Hildesheim and a part of the Petrosia treasures, as well as a number of the best specimens of collage and corporation plate. The museum handbooks on this subject by J. H. Pollen and W. Cripps are extremely useful to the student. The same department has also published a most valuable *List of Works of Gold- and Silver-smiths' Works in the National Art Library*. 1882.

*Modern Plate in the East.*—Though little plate of real artistic merit is now made in Europe, in the East, among the Moslem and Hindu races, there still survive some real taste in design and skill in execution. Delhi, Benares, Lucknow, Cutch, and other places in India and Kashmir still produce a quantity of beautiful silver and gold work,—chiefly ewers, basins, rose-water sprinklers, salvers, coffee-pots, and the like. These are of graceful form, covered with rich repoussé work, or more often with very delicate chased patterns. Their style in the main is Moslem, but some combine an Arab form with native Indian surface decoration. This class of work is not a revival, but has been practised and handed down by unbroken tradition, and with little or no change in style from the 16th century or even earlier.<sup>1</sup> The silversmiths of Persia, Damascus, and other Eastern places are still skilful, and retain some good tradition in their designs. They are, however, more occupied in the production of personal ornaments than in making larger works of silver or gold.

(J. H. M.)

PLATE, THE RIVER, or RIO DE LA PLATA ("River of Silver"), in South America (see vol. ii. Plate xxv., and vol. iv. Plate xvii.), was at first known as Rio de Solis, after Juan Diaz de Solis, who discovered it in 1515, and lost his life on its banks. The present name, a double misnomer, was bestowed by Sebastián Cabot, who, ignorant that he was on the wrong side of the continent, though he had reached a country of mineral wealth—a mistake (perpetuated also in the designation Argentine Republic) which may be said to have received a kind of poetic justification in the fact that the distant mines of Potosi lie within the drainage area of the La Plata system. Like Rio Grande do Sul and Rio de Janeiro on the Brazilian coast, this Rio is not a river but a vast estuary into which rivers discharge. At its narrowest it is 23 miles across, opposite Buenos Ayres 34 miles, and opposite Montevideo 63 miles. By some writers the conventional limit between estuary and ocean is drawn from Montevideo, where the water is still fresh enough to be drunk; but others go farther out and take the line 150 miles across from Maldonado to Cabo San Antonio. In the former case the length of the estuary is 125 miles. At one time it must evidently have extended 200 miles farther inland to Diamante, at the bend of the Paraná; and nature is steadily and rapidly at work prolonging the rivers proper at the expense of the estuary. At low water the average depth may be taken at 18 feet, and shoals and sandbanks are abundant, especially in the upper end. Nearly the whole expanse between Buenos Ayres and Martin Garcia Island is between 3 and 6 feet deep, and a great portion is even shallower. In the shallower portions the bottom consists of a very fine hard-grained sand, in the deeper portions of a sticky ooze. The tidal movement is so disguised by the more obvious effects of wind that Mr Révy found people who had lived all their lives on the banks ready to deny its existence. But at Buenos Ayres the normal neap-tide is 5 feet 3 inches above ordinary low water, and the spring tides vary from 6 to more than 10 feet. The region being one of "storms and extraordinary electric disturbance," with the pampero at one time blow-

<sup>1</sup> See *Endwood Industrial Arts of Iowa*, 1890, p. 144.

ing hard from the land and at another a sea wind driving the ocean before it, the ordinary levels and currents are often violently disturbed. The general slope of the surface may even be reversed, and the main current of estuary and river run up stream for a hundred miles or more. It has been estimated that the volume of water poured into the Rio de la Plata exceeds the aggregate discharge of all the rivers of Europe put together. Nor need this be matter of surprise when the enormous extent and the character of the drainage area are taken into account. The headwaters of the Rio Blanco (a feeder of the Pilcomayo sub-system) rise only 125 miles from the coast of the Pacific, in  $68^{\circ} 10'$  W. long., and those of the Rio Grande are not more than 70 miles from the coast of the Atlantic, in  $44^{\circ}$  W. long.; the basin thus extends east and west over twenty-four degrees of longitude, or 1500 miles, and the direct distance from the northmost source to the mouth of the Paraná is about as great. A considerable proportion of this vast area lies within the tropics, and receives an abundant rainfall, which, owing to the character of the strata, is largely carried off by the surface drainage. As an instance of the effect of this rainfall on even the secondary tributaries, Mr Bigg-Wither's experience may be cited: at Jatahy on the Tibagy he was detained from the 2d to the 25th of July by the river, after nine days of incessant downpour, rising 33 feet at a place where it was 200 yards wide, and pouring along a volume of 90,000 cubic feet per second, or twenty-five times its low-water volume (see *Journ. Roy. Geogr. Soc.*, 1876).

The three great rivers of the La Plata system are the Paraná, its equal affluent the Paraguay, and the Uruguay—the second being the most important as a waterway, and the first the most interesting from its physical features.<sup>1</sup> As the general course of the Paraná and the Paraguay, both of which rise in Brazil, has already been sketched in the article on that country (vol. iv. p. 222), it simply remains to direct attention to a few points of interest. In regard to the great "Seven Falls" of the Paraná, we have still no better account than that of Azara in the 18th century; but the Hundred Cataracts or Victoria Falls of the Curityba or Y-guazu have been described in detail by the members of the first Germano-Argentine colonial land-surveying expedition to Misiones in 1883 (see *Verhandl. d. Ges. f. Erdkunde zu Berlin*, vol. x. pp. 357–364). For combined beauty and grandeur of scenery they claim to rank among the foremost cataracts in the world. About 6 or 7 miles higher up the river is 3 miles broad; it gradually narrows until, after passing through a perfect labyrinth of islands (King Albert Archipelago), it pours, not in a single mass, but in numerous streams, over a horse-shoe edge of rock into a gorge 120 to 150 feet deep. Niederlein divides the falls into three groups—a northern or Brazilian, a central or insular, and a southern or Argentine, to which he has attached respectively the names of the Emperor Don Pedro, the Emperor William, and General Roca. The river continues for some distance shut in by overhanging cliffs; and a large number of secondary cataracts (Bosetti Falls, Prince Bismarck Falls, &c.) are formed by tributary streams, and add to the bewildering beauty of the scene.

The watersheds between the north-eastern headwaters of the Paraguay system and the southern affluents of the Amazons are so low and narrow that in some instances canoes have been conveyed overland from the one to the other. Interest has recently been concentrated on the exploration of the Pilcomayo, a right-hand tributary which joins the Paraguay proper in  $25^{\circ} 20'$  S. lat. Though its sources have long been known, all attempts to trace it downward from Bolivia or upward from the Argentine Republic

had been foiled by the hostility of the Indians. At length, on April 27, 1882, Dr Crevaux, the great French explorer of South-American rivers, was slain with all his party by the Tobas at a place called Ipanticapu. General interest was thus aroused; and the task in which Dr Crevaux perished has since been practically accomplished by Dr Thouar, his fellow-countryman, who, leaving the San Francisco mission-station on 10th September 1883, reached the mouth of the river on 10th November, though he had not been able to keep close to its course in the lower section of the journey. The Pilcomayo rises in Vilcapujia (a mountain 13,500 feet high to the E. of Lago Poopo), and passes between the Cordillera of Livichuco and the Cordillera de los Frailes, a few miles to the north of Potosi. It cuts through the last range of the Andes in  $21^{\circ} 16' 50''$  S. lat. and  $63^{\circ} 25'$  W. long., and enters the plains of the Gran Chaco at a height of 1456 feet above sea-level (J. B. Minchin<sup>2</sup>). It is soon after joined by the Pilaga, which brings down the waters of the Rio Blanco and other streams from the mountains. Till in its south-eastern course it reaches  $22^{\circ}$  S. lat., the river has a very regular course, flowing at the rate of 6500 feet per hour over a sandy bed 800 to 700 feet wide, unimpeded by rocks or trees, and enclosed by steep banks 15 to 20 feet high, above which the country stretches out in pasture-covered plains. Farther down the banks increase in height to from 20 to 45 feet, and embrace a channel or valley 5500 feet or more in breadth, though the actual river does not exceed 150 or 200 feet. At the point called Cabello Muerto,  $24^{\circ} 20'$  S. lat., commence the marshy plains of the lower course, in which the banks hardly rise above the level of the water, and a whole series of lagoons lie at a distance of a mile or two on the left hand. So flat is the country, and so tortuous the river that when Mr Robinson, in 1873, ascended for 150 miles, he never lost sight of the white houses of Asuncion.<sup>3</sup>

About 150 miles below the mouth of the Pilcomayo the Paraguay is joined by another Andean river the Rio Vermejo or Y-pyta, whose red waters, pouring into the dark clear water of the main stream, are sufficient to tinge the whole current downwards to the confluence of the Paraná. "From the junction of its headstreams down to the Paraguay, the Vermejo does not receive a single affluent; its breadth varies from 70 to 250 yards, its depth from 5 to 16 feet; and the current appears to average  $1\frac{1}{2}$  miles an hour" (Keith Johnston). Its navigability was shown about 1780 by the Franciscan missionaries Murillo and Lapa descending the whole way in a canoe, but it was not till 1874 that, under Don Natalio Roldan, the regular navigation was undertaken.

At their confluence the Paraguay has a width of half a mile, the Paraná of 3 miles. The united river continues for 686 miles, first in a south-south-west, then in a south, and finally in a south-east direction before it reaches the head of the La Plata estuary. Down to Diamante, or for 433 miles, its left bank is at intervals formed by lines of bold bluffs from 100 to 200 feet high, on which several of the more important towns are built; but the channel often breaks up so as to enclose extensive islands. The worst reach in this respect is the 45 miles below Goya, a little town in  $29^{\circ} 7'$  S. lat. At Diamante begins the enormous delta (some 5000 or 6000 square miles) which is traversed by countless and changing channels, and presents nothing else, even if viewed from the masthead of the steamer, but a boundless labyrinth of islands clothed with exuberant vegetation. The two chief lines of navigation through this deltaic region are the Paraná de las Palmas (so called by Cabot, in 1526, but now showing comparatively few palms among its ceibos, willows, and poplars) and the Paraná Guazu. The former has its mouth about 24 miles north of Buenos Ayres, the latter joining the estuary of the Uruguay 22 miles farther north, in  $34^{\circ}$  N. lat. and  $58^{\circ} 24' 30''$  W. long.

The third great confluent of the La Plata system, the Uruguay, is quite unlike the other two. Instead of having a fairly steady and continuous flow, it appears sometimes as an insignificant torrent and at other times as a magnificent river. It has its headwaters in the Serra Geral, and for several hundred miles continues to flow west through Brazil (forming the northern boundary of Rio Grande do Sul province), as if it meant, like the Curityba, to carry its waters to the Paraná; but about  $54^{\circ}$  W. long. it is turned aside by the mountain range of Misiones, and flows south-west and south almost parallel with the Paraná. It has a total length of 950 miles, and a drainage area of 200,000 square miles.

In the matter of annual rise and fall the three rivers differ considerably. The Paraguay is regular, reaching its lowest stage in the end of February, and its highest about the end of June, and showing an average difference of level not exceeding 15 feet. The ordinary flow at Asuncion is between 97,400 and 99,950 cubic feet per second. Above the junction of the Paraguay the Paraná appears to have numerous and rapid risings at irregular intervals, but to reach its maximum in December. Below the junction it has much the same movement as the Paraguay, having high water in sum-

<sup>1</sup> The word Paraná, meaning simply river, appears, it is to be remembered, alone or in composition again and again throughout South America. See Lallemant, in *Zeitschr. für Erdk.*, Berlin, 1863, p. 156.

<sup>2</sup> "Eastern Bolivia, &c.," in *Proc. Roy. Geogr. Soc.*, 1881.

<sup>3</sup> See Thouar's account in *L'Exploration*, 1884; and map of the Pilcomayo, in *Bol. Inst. Geogr. Argentino*, 1882.

men, gradually shrinking through September, October, and December, flooding in January, and continuing high and steady till June. The Uruguay rises about the middle of January (at Salto sometimes 22 feet above low water; again in April, to continue in flood for two months (30 feet at Salto); and for the third time, and with great regularity, in September or October, to last a whole month, and reach 40 to 50 feet above low water. Occasionally the flood level of the Paraná is maintained throughout a whole year, or even two years in succession; and at intervals, as in 1855 and 1863, the water rises so high that the whole delta is submerged. The highest floods on record stood 24 feet above ordinary low-water mark at Rosario, or 12 feet above ordinary high water. As a system of waterways the La Plata rivers are but partially developed. Steamers, mainly Brazilian, ascend from Buenos Ayres by the Paraná, Paraguay, and Uruguay, a total distance of 2145 miles, to the town of Corumbá in Brazil; and the Pilcomayo and the Vermejo, the Apa, the Joray, and the Telliary are all more or less navigable. The Paraná affords a free passage for 250 miles above the confluence to the Seven Falls, except during low water, when the rapids of Apipé interfere; and, according to Bigg-Wither, the upper Paraná and its tributaries the Tibagy, Paranápatema, Tite, Itaty, &c., furnish 1250 miles of navigable stream, of which 510 could be at once utilized by steamers of light draught, while the remainder would require a certain outlay in the way of improvements. Vessels drawing 4½ feet of water can always ascend the Uruguay to Salto (250 miles), and during six months they can cross the Salto Chico, or Little Fall, a mile higher up; but the Salto Grande, 3 miles farther, stops all progress except during six weeks in October and September. The whole system may be estimated to give upwards of 5000 miles of waterway, of which 2500 are accessible from the sea, without counting the secondary delta channels.

See T. N. PEAR, U.S.N., *La Plata*, 1879 (the surveys of the "Waterwitch").  
See also *Geographical Dictionary*, 1871; *Encyclopædia Britannica*, 1875; J. J. Lamy, *Hydrographie des Grands Lacs: le Paraná, le Uruguay, et le La Plata*, 1876; and a series of elaborate investigations and measurements of great value, and full of most interesting facts, by PARAGUAY. (H. A. W.)

PLATEAU, JOSEPH ANTOINE FERDINAND, was born at Brussels in 1801, and died in 1863 at Ghent, where he had been professor of physics from 1835. He was a pupil and friend of Quetelet, who had much influence on the early part of his career. The more original investigations of Plateau refer chiefly to portions of one or other of two branches of science—physiological optics and molecular forces. His doctoral thesis (Liège, 1829) had for its subject "Impressions produced by Light on the Organs of Vision"; and it was succeeded by numerous memoirs, some of much value, on the persistence of visual impressions, subjective impressions of colour, irradiation, &c. Among other results of his studies was the invention of the philosophical toy known as the "thaumatrope." We owe to him also something much more important, the process of studying the motion of a vibrating body by looking at it through equidistant radial slits in a revolving disk. In 1829 he imprudently gazed at the midday sun for 20 seconds, with the view of studying the after effects. The result was blindness for some days, succeeded by a temporary recovery; but for the next fourteen years his sight gradually deteriorated, and in 1843 he became permanently blind. This calamity did not interrupt his scientific activity. Aided by his wife and son, and afterwards by his son-in-law Van der Mensbrugghe, he continued to the end of his life his researches on vision,—directing the course of the experiments which they made for him, and interpreting the bearing of the results. He also published a valuable analytical catalogue of all the more important memoirs which had been written, from the earliest times to the end of the 18th century, on his favourite theme of subjective visual phenomena. But even more extraordinary were this blind man's investigations about molecular forces, embracing hundreds of novel experiments whose results he saw only with others' eyes. These form the subject of his great work *Statique expérimentale et théorique des Liquides soumis aux seules Forces moléculaires* (2 vols., 1873), which is a valuable contribution to our knowledge of the phenomena usually called capillary. To avoid, as far as possible, complications due to gravity, Plateau employed either films formed of a solution of soap with

glycerin, or masses of oil suspended in a mixture of alcohol and water of the same density as the oil. See CAPILLARY ACTION.

PLATED WARE. The plating or coating of one metal or alloy with another is extensively practised in metal working. In some cases the coating metal is a valuable protector from oxidation, &c., of the underlying metal; in other cases the properties and advantages of two metals—such as strength and lustre—are combined in one object; and more frequently a cheap and inferior body by a superficial coating gets the appearance of a more valuable and important metal. The art of plating was originally applied to the production of imitation silver plate, whence the term "plating." The original method of silver plating consisted in attaching, by a kind of autogenous soldering, thin plates of silver to the opposite surfaces of a prepared ingot of copper alloy or of German silver. The silver plates were firmly wired to the ingot and submitted to a soldering temperature in a plating furnace, in which the surfaces became firmly united. Subsequently the ingot was rolled down to a sheet in which the relative thickness of the metals was maintained, and from such sheets "silver plated" articles were fashioned. This method of plating may be regarded as now extinct, being superseded by electro-plating (see ELECTRO-METALLURGY, vol. viii. p. 114). Recently, however, cooking vessels, &c., of iron plated in an analogous manner with nickel have come into use (see NICKEL, vol. xvii. p. 488). The plating or casing of iron with brass is extensively practised in the manufacture of stair-rods, curtain and picture rods, and "cased" tubing for upholstery purposes generally; and in the manufacture of pipes for conveying water the body of lead is frequently lined with a coating of pure tin. The gilding of metals is a process analogous to plating, as are also the galvanizing of iron and the manufacture of tin and terne plates. For these see IRON, vol. xiii. p. 357.

PLATEN-HALLERMUND, AUGUST, GRAF VON (1796–1835), German poet, was born at Ansbach on October 24, 1796, and died at Syracuse on December 5, 1835. His principal publications were *Lyrische Blätter* (1821), *Sonette aus Venedig* (1825), an historical fragment entitled *Geschichte des Königreichs Neapel 1414–43* (1833), and a poem in nine cantos, *Die Alkiden* (1835). He wrote also a number of dramas, of which may be mentioned *Der gläserne Pantofel* and *Die Liga von Cambrai*. See vol. x. p. 545.

PLATINUM AND THE PLATINUM METALS. The metals platinum (Pt), palladium (Pd), rhodium (Rh), iridium (Ir), ruthenium (Ru), and osmium (Os) are united into a family by a striking similarity in chemical characters and by their association in natural occurrence. A rather rare ore, called platinum ore or polyxene, is almost the only native material which is available for their extraction; it contains them all in the reguline form. *Traces* of platinum are found in almost all native gold.

As early as the first half of the 16th century it appears to have been noticed that the gold ore in the Spanish mines of Darien includes grains of a white metal, endowed with the qualities of a noble metal and yet distinctly different from silver; but the fact remained unknown in Europe because the Spanish Government, having found out that the new metal lent itself most admirably for the adulteration of gold, prohibited its exportation. Only from about the middle of last century did the metal begin to find its way to Europe and to become known there, at first as a curiosity, under its Spanish name of "platina del Pinto" (the little silver from the river Pinto). Its chemical individuality and qualities were established by the successive labours of Scheffer (1752), Marggraf (1757), Bergmann (1777), and others. An amateur, Count von Sickingen, it appears, was the first who succeeded in work-

ing the metal (1772); the first platinum crucible was produced by Achard (1784). Achard's mode of rendering the native metal amenable to mechanical working was founded upon the fact that it forms a readily fusible alloy with arsenic, from which the latter can be driven off again by intense heating. This method was worked industrially for a time, but subsequently superseded by another superior process, which is usually credited to Wollaston, because it was he who, after having wrought it as a rich source of revenue for years, published it in 1828. But as early as 1800 Knight of London had published all that is essential in the process; and Messrs Johnson, Matthey, & Co. inform the writer that Wollaston obtained the secrets of both the refining and the compressing of the spongy into compact metal from a relative of theirs, Thomas Cock, who, they are convinced, is the true inventor. Undisputed merits of Wollaston's are his discoveries of palladium (1803) and rhodium (1804). About the same time iridium and osmium were discovered by Smithson Tennant.

Platinum ore well deserves its cognomen of "polyxene," because it is a most complex mixture of mineralogical species, including (1) a number of heavy reguline species designated as platinum, osmiridium, iron-platinum, platinum-iridium, iridium, palladium (also gold), and (2) a number of non-metallic species, notably chrome-iron ore, magnetic oxide of iron, zircon, corundum, and occasionally also diamond. The reguline components always form detached granules, which are generally small, but occasionally assume considerable dimensions. The Demidoff museum contains a native platinum lump weighing 21 pounds troy. The ore, as already stated, was discovered first in South America; it is found there chiefly in the provinces of Choco and Barbacos, New Granada, and also in Brazil. It occurs besides in San Domingo, in California, at the Rogue river in Oregon, in Canada, and in the island of Borneo. But the richest deposits are those of the Ural Mountains; these were discovered about 1823, and have been wrought by the Russian Government since about 1828. Part at least of the Ural ore, as Daubré showed, was embedded originally with chrome-iron in a serpentine derived from olivine. The very variable percentages of the several components range approximately as follows:—platinum, 60 to 87; other polyxene metals 3 to 7; gold up to 2 and more; iron 4 to 13; copper 0 to 4; non-metallic gangue 1 to 3.

Platinum, though a noble metal chemically, has too modest an appearance to lend itself much to the jeweller's purposes. The Russian Government used, for a while, to strike platinum coins, but soon came to give up the practice on account of the immense fluctuations in the commercial value of the metal. Almost all the platinum produced now-a-days is made into chemical utensils. Platinum, in fact, is the metal of the chemist. "Without platinum crucibles, which share the infusibility of porcelain with the chemical inertness of gold ones the composition of most minerals could not have been ascertained" (Liebig), and chemistry generally could not have come up to its present level. In industrial chemistry platinum is used chiefly for the construction of those stills for the concentration of oil of vitriol which, although a single one costs a fortune, are cheaper in the long run than glass retorts.

The technical extraction of platinum from its ore is to the present day effected everywhere by some modification or other of the so-called "Wollaston" process. Heraeus of Hanau operates as follows. The ore is digested within glass retorts in aqua regia diluted with three times its weight of water, an over-pressure of some 12 inches of water being established within the retorts to accelerate the process, which always takes several days. The whole of the osmiridium, along with more or less of other polyxene metals, and the "sand" (corundum, chrome-iron, &c.) remain undissolved, as a heavy black deposit; the platinum, palladium, part of the rhodium, and more or less of the other three

polyxene metals pass into solution, the platinum, iridium, and palladium as tetrachlorides. From the clarified solution the whole (almost) of the platinum can be precipitated as  $\text{PtCl}_2(\text{NH}_4)_2$  by addition of a large excess of sal-ammoniac; and this simple process used to be adopted formerly. But the precipitate then includes much chloro-iridate of ammonium  $\text{IrCl}_6(\text{NH}_4)_3$  and other impurities. Heraeus, therefore, first evaporates to dryness and heats the residue to 125° C. for a sufficient time, to reduce the palladic and iridic chlorides to the lower stages of  $\text{PdCl}_2$  and  $\text{IrCl}_3$ , which form soluble double salts with sal-ammoniac. The heated residue is dissolved in water acidulated with hydrochloric acid, the solution filtered, and mixed with hot concentrated solution of sal-ammoniac, when a (relatively) pure chloroplatinate comes down as a yellow precipitate (the iridium compound is dark-red), which is washed, first with saturated sal-ammoniac solution, then with dilute hydrochloric acid. The precipitate needs only be exposed to a dull red heat to be converted into "spongy platinum," i.e., metallic platinum in the form of a grey porous mass. As platinum is infusible even at the highest temperature producible in a wind-furnace, the spongy metal cannot be fused together into a regulus like an ordinary metal; but it shares with wrought iron the rare quality of assuming a high degree of softness and viscosity at a strong red heat; and consequently the sponge, after a preliminary compression by purely mechanical means, needs only be exposed to a strong heat to "frit" into a coherent mass; and this mass, by repeated forging at a white heat is readily made into a perfectly homogeneous compact bar, which, as the metal is very ductile, is easily rolled out into sheet or drawn into wire. In the former form more especially it goes into the workshop to be made into utensils.

This process of welding at the time of Achard (who used it first) and of Knight was a necessary make-shift; but it is singular that it was retained long after the invention of the oxyhydrogen blast (see vol. xviii. p. 105), by means of which platinum can be fused as easily as lead can in an ordinary fire. With the oxyhydrogen-blowpipe Hare, as early as 1847, fused 970 grammes (upwards of two pounds) of platinum into one regulus. Yet platinum manufacturers did not utilize this obvious process until Deville and Debray, in 1859, again demonstrated its practicability. Their furnace is of the simplest description. Two flat pieces of quicklime, scooped out so as to represent two cupels, are placed one upon the other so that they enclose a flat space similar in form to two superimposed soup-plates. The lower cupel has a notch cut out of its side to serve as a spout for pouring out the liquefied metal, the upper and shallower one is pierced with a central slightly conical round hole through which the (platinum) nozzle of the blowpipe enters, so that the flame flattens itself out on the introduced metal. By means of this simple contrivance Deville and Debray had no difficulty in fusing as much as twelve kilogrammes of platinum into one regulus; and Messrs Johnson, Matthey, & Co. of London now think nothing of fusing up as much as 1000 ounces of metal in one operation. A regulus made under Mr Geo. Matthey's superintendence for the metric commission in Paris in 1874 weighed one quarter of a ton.

The shaping of compact platinum is effected pretty much in the same way as that of gold or silver; only the difficulties are less because platinum, unlike the two ordinary noble metals, is susceptible of "welding"; i.e., two pieces of the metal, at a white heat, can be united into one by a stroke of the hammer. Soldering is rarely necessary; it used to be effected (and still is occasionally) by means of gold as a connecting medium and an ordinary blowpipe. But platinum workers, following the lead of Messrs Johnson, Matthey, & Co., have long learned to unite two platinum seams by the "autogenic" process—the local fusing of the two contiguous parts in the oxyhydrogen flame.

For the preparation of chemically pure platinum Schneider's process is the one most easily executed and explained. The commercial metal is dissolved in aqua regia and the excess of nitric acid removed by evaporation to a syrup in a water-bath. The residue is redissolved in water and boiled for a long time with a large excess of potash-free caustic soda. If care be taken to maintain a strong alkaline reaction, all the foreign polyxene chlorides are reduced to lower forms than that of tetrachloride; while only the platinum itself retains this state of combination. The hypochlorite formed is then reduced (to  $\text{NaCl}$ ) by addition of a little alcohol to the boiling alkaline liquid, which is now allowed to cool and acidified strongly with hydrochloric acid so as to redissolve any hydrated platonic oxide which may have been precipitated by the first instalments of acid. The liquid at last is filtered, and precipitated by sal-ammoniac to obtain a pure chloroplatinate ( $\text{PtCl}_2(\text{NH}_4)_2$ ), which, on ignition, of course, yields an equally pure spongy metal.

Pure compact platinum is a tin-white metal about as soft as pure copper and nearly (but not quite) equal in plasticity to gold. The specific gravity of the fused metal is 21.48 to 21.60 at 17°-6 C. (Deville and Debray). The breaking strain is 34.1 kilos for hard-drawn and 23.5 kilos for annealed wires; the modulus of elasticity 15,518 (kilogramme and millimetre as units; by Werthum's ex-

periments on annealed welded wire). Unit length of the (fused) metal expands by 0.000907 from 0° to 100° C. (Fizeau). The specific conductivity for heat at 12° C. is 8.4, for electricity at 0° C. 16.4 (silver=100). The statement regarding electricity refers to the annealed metal. The fusing point, according to recent determination by Violle, is 1779 C.; the same experimenter finds for the true specific heat  $\delta Q/\delta t = 0.0317 + 0.000012t$  (centigrade scale). When platinum is heated beyond its fusing point, it soon begins to volatilize. The fused metal, like silver, absorbs oxygen, and consequently "spits" on freezing. At a red heat the then viscid metal, as Graham has shown, "occludes" hydrogen gas; i.e., it dissolves the gas (just as, for instance, liquid water would), which explains the fact previously discovered by Deville that a platinum tube, although it may be perfectly gas-tight in the cold, at a red heat allows hydrogen (but not, for instance, oxygen, nitrogen, or carbonic acid) to pass through its walls. According to Graham the quantity of gas occluded is independent of the surface of the metal operated on, but proportional to its weight. No gas is taken up in the cold; but the gas occluded at a red heat, though extractable at that temperature by means of an absolute vacuum as producible by a Sprengel pump (see *MERCURIAL AIR PUMP*, vol. xvi. p. 20), is retained on cooling and cannot be thus liberated at the ordinary temperature. The volume of hydrogen absorbed by unit-volume of metal at a red heat under one atmosphere's pressure was found, in the case of fused metal, to vary from 0.13 to 0.21 volume measured cold; in the case of merely welded metal, from 2.34 to 3.8 volumes (compare *Palladium* below). Oxygen gas, though absorbed by the liquid, is not occluded by the solid metal at any temperature, but when brought in contact with it at moderate temperatures suffers considerable condensation at its surface. The thin condensed film of oxygen exhibits a high degree of chemical activity: a perfectly clean piece of platinum foil, when immersed in a mixture of hydrogen or ammonia or other combustible gas and air, begins to glow and starts a process of slow combustion or there may be an explosion. The spongy metal of course exhibits a very high degree of activity: a jet of hydrogen gas when made to strike against a layer of spongy platinum causes it to glow and takes fire. This is the principle of the (now defunct) Döbereiner lamp. But the most striking effects are produced by a peculiar kind of very finely divided platinum, which was discovered by Liebig and called by him platinum black on account of its resemblance to lamp-black. A particularly active " . . . . . " by dropping platinum chloride solution into a boiling mixture of three volumes of glycerin and two of caustic potash of 1.05 specific gravity. Platinum black, according to Liebig, absorbs 800 times its volume of oxygen from the air, and in virtue thereof is a most active oxidizing agent, which, in general, acts "catalytically" because the black, after having given up its oxygen to the oxidizable substance present, at once takes up a fresh supply from the atmosphere. For examples see *FERMENTATION*, vol. ix. pp. 94-95.

#### Platinum Alloys.

Platinum alloys of almost any kind are easily produced synthetically; and, as a rule, a temperature little if at all above the fusing point of the more fusible component suffices to start the union. We will begin with the cases in which the metal combines with another member of its own family. *Iridium*.—In the heat of an oxyhydrogen flame the two metals unite permanently in all proportions. The alloy has pretty much the appearance of platinum, but it is less fusible, harder, more elastic, specifically heavier, and less readily attacked by aqua regia,—all these qualities increasing as the percentage of iridium increases. The 19 per cent. alloy was produced for the first time by G. Matthey. It has the hardness and elasticity of soft steel (modulus of elasticity=22,000 for millimetre and kilogramme), and is hardly attacked by aqua regia. Alloys richer in iridium are difficult to work. The 10 per cent. alloy on the other hand still retains enough of the virtues referred to to be far superior to platinum itself—perhaps we might say, to any other solid—as a material for standard measures of length or weight. In 1870 Messrs Johnson, Matthey, & Co. exhibited a standard metre made of this alloy, and it gave such unqualified satisfaction that the international metric committee which sat in Paris some years ago adopted it for the construction of their standards. *Rhodium*.—An alloy of 30 per cent. of this metal and 70 of platinum is absolutely proof against aqua regia, but is very expensive. Deville and Debray once elaborated an igneous process for producing, directly from the ore, a triple alloy of platinum, iridium, and rhodium, which is quite workable and, besides being more highly infusible than platinum, is almost proof against aqua regia. Crucibles made of this alloy used to be sold in Paris and elsewhere at moderate prices; but they are now no longer to be had. *Gold*.—This metal unites with platinum in all proportions, forming greyish-yellow or greyish-white alloys. A graduated series of these alloys was recommended by Scherrel and Ehrhard as a means for defining certain ranges of high temperatures. According to their experiments, while the fusing-point for gold was 1075° C., and for platinum 1775°, it was 1130° for 10 per cent. of platinum, 1190°

for 20, 1255° for 30, 1320° for 40, 1385° for 50, 1460° for 60, 1535° for 70, 1610° for 80, and 1690° for 90 per cent. *Silver* and platinum unite readily in any proportion, but the alloys are in general liable to "liquation" (see *METALS*, vol. xvi. p. 67). Now platinum is as proof against nitric acid as gold; and yet these alloys cannot, like gold-silver, be parted by means of nitric acid; because, if the alloy is rich enough in silver to be at all attacked by the acid, part at least of the platinum passes into solution along with the silver. But concentrated oil of vitriol effects a sharp separation; the platinum remains. A considerable variety of alloys of platinum with other noble metals are used in mechanical dentistry. The following examples may be quoted:—66.7 per cent. of gold and 33 of platinum; platinum 50, silver 25, palladium 25; platinum 41.7, gold 25, palladium 33.3.

Of the great variety of alloys of platinum with base metals which have been recommended as substitutes for noble metals or otherwise we select the following:—

	Platinum.	Silver.	Copper.	Tin.	Brass.	Nickel.
1	19	0	1	0	0	0
2	1	0	26	0	0	0
3	2	1	5	0	2	1
4	1	0	0	10	0	100
5	1	2	0	20	0	100
6	0.5	0	0	15	0	100
7	20	0	0	20	0	100
8	5 to 10	0	0	0	120	60

(1) Known to jewellers and dentists as hard platinum; (2) a rose-coloured fine-grained ductile alloy; (3) introduced by Bolzani in Paris as an imitation gold; (4 to 7) platinum bronzes, recommended—(4) for knife and fork handles, (5) for bells, (6) for articles *de luxe*, (7) for telescopes; (8) not subject to oxidation.

#### Platinum Compounds.

Platinum is not changed by air, water, or steam at any temperature. It is proof against the action of all ordinary single acids, including hydrofluoric, in the heat or cold. Aqua regia (a mixture of hydrochloric and nitric acids) dissolves it slowly as chloroplatinic acid  $PtCl_4H_2$ . The metal is not attacked by even very strong boiling caustic potash or soda ley, nor is it changed by fusion with carbonate of soda or potash. Carbonate of lithia, and the hydrates of potash, soda, and baryta, however, when fused in platinum vessels, attack them strongly, with formation of compounds of  $PtO_2$  with the respective bases. According to recent experiments by the writer, none of these reactions go on in the absence of air; hence, for instance, a fusion with caustic baryta or potash can safely be carried out in a platinum crucible if the latter is protected by an atmosphere of hydrogen or nitrogen. Fused hepar (alkaline sulphide) dissolves platinum at a red heat; so does fused cyanide of potassium, especially if mixed with caustic potash.

*Chloroplatinic Acid*.—The solution of the metal in aqua regia is evaporated down repeatedly in a water bath with hydrochloric acid to destroy the excess of nitric acid and the very concentrated solution allowed to stand, when the acid gradually separates out in brown-red deliquescent crystals of the composition  $PtCl_4H_2 + 6H_2O$ , which are abundantly soluble in water and also easily in even strong alcohol. The aqueous solution, if free of iridium and platinous chlorides, is of a rich but clear yellow colour free of any tinge of brown. The "chloride of platinum" solution of the analyst is an aqueous solution of this acid. When the solution is mixed with those of certain chlorides, the  $2HCl$  are displaced by their equivalent of metallic chloride, and metallic "chloroplatinates" are produced. Of these the potassium (rubidium and cesium) and the ammonium salts are most easily prepared,—by addition of the respective chlorides to a moderately strong solution of chloroplatinic acid; they come down almost completely as pale yellow crystalline precipitates, little soluble in cold water and very nearly insoluble in alcohol. The sodium salt  $PtCl_4Na_2 + 6H_2O$  and the lithium salt  $PtCl_4Li_2 + 6H_2O$  are readily soluble in water and in aqueous alcohol (the  $Li_2$  compound dissolves even in absolute alcohol); hence "chloride of platinum" is used for the separation of  $K$ ,  $NH_4$ ,  $Rb$ ,  $Cs$  from  $Na$  and  $Li$ . On the other hand chloride of potassium or ammonium may serve as a precipitant for platinum, but in this case a large excess of a concentrated solution of the precipitant must be used to bring the solubility of the chloroplatinate precipitate to its minimum. Gold, copper, iron, and many other metals not belonging to the polyxene group, if present, remain dissolved. Real *platinic chloride*,  $PtCl_4$ , can be produced from the acid  $PtCl_4H_2$  only by precipitating from its solution the chlorine of the  $2HCl$  by the exact equivalent of nitrate of silver. The filtrate when evaporated (cold) over vitriol deposits red crystals of the composition  $PtCl_4 + 5H_2O$ . When chloroplatinic acid is heated to 300° C. it loses its  $2HCl$  and half the chlorine of its  $PtCl_4$  and *platinous chloride*,  $PtCl_2$ , remains as a dull green powder, insoluble in water but soluble in aqueous hydrochloric acid. Either chloride when heated to redness leaves spongy metal. The hydrochloric solution of platinous chloride, when

evaporated with one of chloride of potassium to a sufficiently small volume, deposits rose-coloured crystals of a double salt  $\text{PtCl}_2 \cdot 2\text{KCl} = \text{PtCl}_2\text{K}_2$ . From a solution of this double salt  $\text{PtCl}_2 \cdot 2\text{KCl} = \text{PtCl}_2\text{K}_2$ , is obtained, by boiling it with the *platinous hydrate*,  $\text{Pt}(\text{OH})_2$ , a black precipitate, which, calculated quantity of caustic soda, as a black precipitate, which, when gently heated, becomes anhydrous. *Platinic hydrate*,  $\text{Pt}(\text{OH})_4$ , is obtained by boiling chloroplatinic acid solution with excess of caustic soda and then acidifying with acetic acid, as an almost white precipitate,  $\text{Pt}(\text{OH})_4 \cdot 2\text{H}_2\text{O}$ , which loses its  $2\text{H}_2\text{O}$  at  $100^\circ \text{C}$ . and becomes brown; at a certain higher temperature it loses all its water and assumes the form of the black anhydride  $\text{PtO}_2$ . Both oxides are bases in so far as their hydrates combine with a limited number of acids; towards strong bases they behave as feeble acids. Only a few of the salts of the acid  $\text{PtO}_2$  have been investigated. Either oxide when heated to redness breaks up into oxygen and metal.

*Platin-Ammonium Compounds.*—In this very numerous family of bodies a compound radical containing platinum and some ammonia residue plays the part of a basulous metal. The first member was discovered by Magnus in 1828. By adding ammonia to a hydrochloric solution of platinous chloride, he obtained a green precipitate of the composition  $\text{PtCl}_2 \cdot \text{N}_2\text{H}_4$ , which soon became known as "Magnus's green salt," and served as a starting point for subsequent investigations.

*Platinocyanides.*—These were discovered by L. Gmelin, who obtained the potassium salt  $\text{Pt}(\text{NC})_4\text{K}_2$  by fusing the metal with prussiate of potash. Martius's method is more convenient: chloroplatinate of ammonia is heated in a strong mixed solution of caustic potash and cyanide of potassium as long as ammonia is going off. The solution on cooling deposits crystals containing  $3\text{H}_2\text{O}$  of water, which appear yellow in transmitted and blue in reflected light. From the potash salt numerous other platinocyanides can be made by double decompositions; and a very interesting series is derived from these by the addition of chlorine or bromine. All these bodies are distinguished by their magnificent fluorescence.

#### The Polyzene Metals Generally.

The metals all exist in the three forms of "black," "sponge," and compact regulina. The colours of the compact metals are shades of white, except in the case of osmium, which forms blue crystals. Platinum, palladium, and rhodium are ductile; the rest break under the hammer.<sup>1</sup> In regard to specific gravity they arrange themselves into two groups as shown by the following table, which at the same time gives the atomic weights (those of Pt and Ir according to Seubert) and the formulae of the most stable chlorides:—

Name.	Atomic Weight. O=16.	Specific Gravity.	Chlorides.
Platinum .....	Pt = 194.3	21.50	$\text{PtCl}_2$ ; $\text{PtCl}_4$ .
Iridium .....	Ir = 193.0	22.38	$\text{Ir}_2\text{Cl}_6$ .
Osmium .....	Os = 195	22.48	(?)
Palladium .....	Pd = 106.6	11.4	$\text{PdCl}_2$ .
Rhodium .....	Rh = 104.3	12.1	$\text{Rh}_2\text{Cl}_6$ .
Ruthenium .....	Ru = 103.5	12.26	$\text{Ru}_2\text{Cl}_6 \cdot x\text{HCl}$ .

The order of fusibility is as follows:—Pd, Pt, Ir, Rh, Ru, Os. Palladium almost fuses in the strongest heat of a wind furnace, but like the four metals following requires an oxyhydrogen flame for its real fusion; osmium has never been fused at all; but it volatilizes abundantly at the highest temperature producible by the oxyhydrogen blast.

*Action of Air.*—Platinum and palladium do not oxidize at any temperature; rhodium also does not oxidize by itself, but when expelled with lead it remains as monoxide  $\text{RhO}$ . Compact iridium does not oxidize appreciably even in the heat; but the finely-divided metal, at some temperature below  $800^\circ \text{C}$ , suffers gradual conversion into  $\text{Ir}_2\text{O}_3$ , which when heated more strongly begins to dissociate at  $800^\circ$ , and is completely reduced at  $1000^\circ \text{C}$ . Ruthenium draws a film of oxide in even cold air; at a red heat it passes into  $\text{Ru}_2\text{O}_3$ , which retains its oxygen at a white heat. Osmium (the finely-divided metal), when heated in air to about  $400^\circ \text{C}$ , takes fire and burns into vapour of tetroxide,  $\text{OsO}_4$ . This and the analogous ruthenium compound are the only volatile oxides of the group.

*Water.*—None of our metals seem to decompose water or steam at any temperature.

*Hydrochloric acid* acts slowly on palladium in the presence of air; otherwise there is no action in any case.

*Hot Nitric Acid* dissolves palladium as nitrate  $\text{Pd}(\text{NO}_3)_2$ , and converts finely divided osmium into tetroxide vapour. Compact osmium, and platinum, iridium, and rhodium in any form, are not attacked by the acid.

<sup>1</sup> It still remains to be seen how far this latter statement holds for the absolutely pure metals. Mr. George Matthey has succeeded in producing iridium wire, which could be bent into a loop without breaking.

*Aqua Regia*, in the heat, dissolves palladium (very readily) and platinum (somewhat more slowly) as  $\text{MeCl}_3\text{H}_2$ ; only the palladium compound is very unstable, being completely reduced to dichloride,  $\text{PdCl}_2$ , by mere evaporation over a water-bath. Iridium black,  $\text{PdCl}_2$ , by mere evaporation over a water-bath. Iridium black, or iridium alloyed with much platinum, dissolves slowly as  $\text{IrCl}_3\text{H}_2$ , readily reducible (by, for instance, addition of alcohol, or evaporation to dryness and heating of the residue to about  $150^\circ \text{C}$ ) to  $\text{Ir}_2\text{Cl}_6$ . Compact iridium, like ruthenium or rhodium, is hardly attacked even by the hot acid; rhodium exhibits the highest degree of stability. Native osmiridium is not touched by aqua regia. Osmium, in the heat at least, becomes tetroxide.

*Free Chlorine* combines directly with all polyzene metals at suitable temperatures. As a disintegrator it is useful chiefly for the manipulation of osmiridium and other such platinum-ore components as refuse to dissolve in aqua regia. The action of the gas is greatly facilitated by the presence of fixed alkaline chloride.

#### Polyzene Oxides and Salts.

*Monoxides* have been produced from platinum, palladium, ruthenium, and osmium.  $\text{PtO}$  and  $\text{PdO}$  are decided, the other two are very feeble bases.

*Sesquioxides*,  $\text{Me}_2\text{O}_3$ , have been got from rhodium, iridium, ruthenium, and osmium. All are basic.

*Binoxides*,  $\text{MeO}_2$ , exist from all the metals except rhodium.  $\text{PdO}_2$ , like  $\text{PtO}$  (see above), is basic or feebly acid;  $\text{IrO}_2$  is a feeble base;  $\text{RuO}_2$  and  $\text{OsO}_2$  are neutral.

*Tetroxides*,  $\text{MeO}_4$ , are formed by osmium and ruthenium only. Both  $\text{OsO}_4$  and  $\text{RuO}_4$  are easily fusible and very volatile solids. Their vapours have a most powerful smell and are most dangerously poisonous.

*Trioxides and Heptoxides* do not exist as substances; but the groups  $\text{RuO}_3$ ,  $\text{OsO}_3$ , and  $\text{R}_2\text{O}_7$  unite with alkalis into soluble salts analogous to chromates and permanganates in their constitution respectively. The oxides  $\text{MeO}$ ,  $\text{Me}_2\text{O}_3$ ,  $\text{MeO}_2$  are as a rule preparable by evaporating a solution of the respective chloride or potassio- &c. chloride to dryness with excess of carbonate of soda, heating the residue to dull redness, and removing the alkaline chloride and excess of carbonate by lixiviation with water. The oxides remain as very dark-coloured powders insoluble in acids. The corresponding hydrates are precipitated from the solutions of the chlorides or potassio- &c. chlorides, on addition of excess of caustic potash or soda and heating. These hydrates of the oxides are soluble in certain aqueous acids with formation of salts, and in this limited sense only the "oxides" can be said to be "bases."

*Salts.*—Of these the most characteristic and the best known are compounds of certain of their chlorides with alkaline chlorides.

1. The compounds  $\text{MeCl}_2\text{R}_2$  (chloroplatinates and analogues), formed by all polyzene metals, except rhodium, are all crystalline salts, more or less soluble in water but as a rule insoluble or nearly so in alcohol. The acids  $\text{MeCl}_3\text{H}_2$ , in which Me is not platinum, exist only as unstable solution, which by the action of excess of caustic soda in the heat, if not by the action of a gentle heat alone, are all reduced to lower chlorides; only the platinum compound possesses a higher degree of stability.

2. Chlorides,  $\text{MeCl}_2$ , and potassio- &c. chlorides,  $\text{MeCl}_2\text{R}_2$ , exist only in the platinum and palladium series.

3. Hexachlorides,  $\text{Me}_2\text{Cl}_6$ , and compounds thereof with other chlorides are formed only by rhodium, iridium, and ruthenium.

#### Preparation of the Rarer Polyzene Metals.

For this the residues obtained in the industrial extraction of platinum from the ore form the natural raw material. These residues are two in number,—(1) that part of the ore which resisted the action of aqua regia (we will call it the osmiridium residue), and (2) the filtrate from the chloroplatinate of ammonia.

1. Part of the osmiridium in the first residue consists of scales or grains so hard that they cannot be powdered even in a steel mortar. They must be reduced to a fine powder, which is best done by fusing them up with eight to ten parts of zinc and then driving off the "solvent" in a wind-furnace. The osmiridium remains as a dark friable mass, which is easily powdered and incorporated with the originally sifted-off part. The disintegration of the residue may then be effected, according to Wöhler, by mixing it with its own weight of common salt and exposing the mixture to a current of chlorine at a dull red heat within a combustion tube. If the chlorine is moist much of the osmium goes off as vapour of tetroxide, which must be collected in solution of caustic potash. After complete chlorination the contents of the tube are treated with water, when as a rule some undisintegrated osmiridium remains which is filtered off. The solution is mixed with nitric acid and distilled as long as any osmic tetroxide vapours are going off, which are readily recognized by their powerful pungent smell, and of course must be carefully collected in caustic potash ley. The residual liquor (which contains the iridium as  $\text{IrCl}_3\text{Na}_2$ ) is supersaturated with carbonate of soda, and evaporated to dryness,

## PLATO

PLATO, the Athenian philosopher and father of idealism, was born 427 B.C., and lived to the age of eighty. His literary activity may be roughly said to have extended over the first half of the 4th century B.C. His father's name was Ariston, and his mother's family, which claimed descent from Solon, included Critias, one of the thirty tyrants, and other Athenian notables. That throughout his early manhood he was the devoted friend of Socrates, that in middle life he taught those who resorted to him in the grove named of Academus, near the Cephissus, and there founded the first great philosophical school, that (with alleged interruptions) he continued to preside over the Academy until his death, are matters of established fact. It is said by Aristotle that he was at one time intimate with Cratylus the Heraclitean. Beyond this we have no authentic record of his outward life. That his name was at first Aristocles, and was changed to Plato because of the breadth of his shoulders or of his style or of his forehead, that he wrestled well,<sup>1</sup> that he wrote poetry<sup>2</sup> which he burnt on hearing Socrates, that he fought in three great battles,<sup>3</sup> that he had a thin voice, that (as is told of other Greek philosophers) he travelled to Cyrene and conversed with priests in Egypt, are statements of Diogenes Laertius, which rest on more or less uncertain tradition. The express assertion—which this author attributes to Hermodorus—that after the death of Socrates Plato and other Socratics took refuge with Euclides in Megara, has a somewhat stronger claim to authenticity. But the fact cannot be regarded as certain, still less the elaborate inferences which have been drawn from it. The romantic legend of Plato's journeys to Sicily, and of his relations there with the younger Dionysius and the princely but unfortunate Dion, had attained some degree of consistency before the age of Cicero, and at an unknown but probably early time were worked up into the so-called *Epistles* of Plato, now all but universally discredited. Nor is there sufficient ground for supposing, as some have done, that an authentic tradition is perceptible behind the myth. For the details of the story the reader is referred to Grote,<sup>4</sup> who believed in the genuineness of the *Epistles*.

It is more important than any further balancing of uncertainties to observe the intellectual tendencies of the preceding generation (c. 430–400 B.C.).

Ante-  
cedent  
tendencies. The later years of the Peloponnesian War witnessed much mental disturbance and restlessness at Athens. Thoughtful minds looked forward with apprehension and backwards with regret, while even the most thoughtless were stirred into superficial activity. More than at any time since the age of Clisthenes, the city was divided, and a man's foes were often men of his own tribe or deme. Athenian politics were more factious and less significant than ever. Contention in the law-courts and rivalries in the assembly had for many men a more absorbing interest than questions of peace and war. Hereditary traditions had relaxed their hold, and political principles were not yet formulated. Yet there was not less scope on this account for personal ambition, while the progress of democracy, the necessity of conciliating the people, and the apportionment of public offices by lot had a distracting and, to reflecting persons, often a discouraging effect.

<sup>1</sup> See *Laus*, vii. 314 c.

<sup>2</sup> Some epigrams in the *Anthology* are attributed to him.

<sup>3</sup> This is told on the authority of Aristoxenus. But Plato cannot have been at Delium.

<sup>4</sup> *History of Greece*, c. lxxiv.; *Plato*, vol. i. c. iii.

For those amongst whom Plato was brought up this effect was aggravated by the sequel of the oligarchical revolution, while, on the other hand, for some years after the restoration of the democracy, a new stimulus had been imparted, which, though of short duration, was universally felt.

The events and circumstances thus briefly summarized appear in two ways to have encouraged the diffusion of ideas. The ambitious seem to have welcomed them as a means of influence, while those who turned from public life were the more stimulated to speculative disputation. However this may have been, it is manifest that before the beginning of the 4th century B.C. the intellectual atmosphere was already charged with a new force, which although essentially one may be differently described, according to the mode of its development, as (1) rhetorical and (2) theoretical and "sophistical." This last word indicates the channel through which the current influences were mostly derived. A new want, in the shape both of interested and of disinterested curiosity, had insensibly created a new profession. Men of various fatherlands, some native Athenians, but more from other parts of Hellas, had set themselves to supplement the deficiencies of ordinary education, and to train men for the requirements of civic life. More or less consciously they based their teachings on the philosophical dogmas of an earlier time, when the speculations of Xenophanes, Heraclitus, or Parmenides had interested only a few "wise men." Those great thoughts were now to be expounded, so that "even cobblers might understand."<sup>5</sup> The self-appointed teachers found a rich field and abundant harvest among the wealthier youth, to the chagrin of the old-fashioned Athenian, who sighed with Aristophanes for the good old days when men knew less and listened to their elders and obeyed the customs of their fathers. And such distrust was not wholly unfounded. For, amidst much that was graceful and improving, these novel questionings had an influence that, besides being unsettling, was aimless and unreal. A later criticism may discern in them the two great tendencies of naturalism and humanism. But it may be doubted if the sophist was himself aware of the direction of his own thoughts. For, although Prodicus or Hippias could debate a thesis and moralize with effect, they do not appear to have been capable of speculative reasoning. What passed for such was often either verbal quibbling or the pushing to an extreme of some isolated abstract notion. That *prudens questio* which is *dimidium scientiæ* had not yet been put. And yet the hour for putting it concerning human life was fully come. For the sea on which men were drifting was profoundly troubled, and would not sink back into its former calm. Conservative reaction was not less hopeless than the dreams of theorists were mischievously wild. In random talk, with gay, irresponsible energy, the youth were debating problems which have exercised great minds in Europe through all after time.

Men's thoughts had begun to be thus disturbed and Socrates eager when Socrates arose. To understand him is the most necessary preliminary to the study of Plato. In our first authentic knowledge of him he is a man in mature life, attracting the attention of his fellow-citizens no less by his courage as a soldier than by his strange-familiar presence in the Athenian agora. Like the cicada of the trees by the Ilissus, his voice was never silent—except when checked by his divine monitor, or when wrapt, as he some-

<sup>5</sup> *Theæt.*, 180 D.

times was for hours, in a catalepsy of reverie (see SOCRATES). When he appeared in the market-place about midday, ready to single out his man for questioning, he had already spent some hours in the wrestling-schools, conversing with the youth. This was not, as it appeared to his contemporaries, mere idleness or mental dissipation (*ἀδολασχία*), but the exercise of his self-chosen profession. There is no reason to doubt the general truth of the assertion which Plato attributes to him in the *Apologia*. He felt a divine vocation to examine himself by questioning other men. Gifted with an iron frame, and having trained himself to have fewer wants than a soldier or a slave, he could devote all his time to this one object, without engaging in remunerative business, or setting hours apart for recreation, since he was indefatigable alike in body and mind. He was really doing for the Athenians, whether they would or no, what the sophist professed to do for his adherents, and what such men as Protagoras and Prodicus had actually done in part. One obvious difference was that he would take no fee. But there was another and more deep-lying difference, which distinguished him not only from the contemporary sophists but from the thinkers of the previous age. This was the Socratic attitude of inquiry.

The sceptical movement had confused men's notions as to the value of ethical ideas.<sup>1</sup> "If 'right' is one thing in Athens and another at Sparta, why strive to follow right rather than expediency? The laws put restraint on Nature, which is prior to them. Then why submit to law?" And the ingenuities of rhetoric had stirred much unmeaning disputation. Every case seemed capable of being argued in opposite ways. Even on the great question of the ultimate constitution of things, the conflicting theories of absolute immutability and eternal change appeared to be equally irrefragable and equally untenable.

Now Socrates first of all maintained imperturbably the simple habits of an ordinary Athenian citizen, observing scrupulously even minute religious customs, entering also unreservedly into the lightest pastimes of his associates, while the plain and strenuous tenor of his own peculiar life remained unaffected. But into all he carried the same irrepressible, insatiable spirit of search, to which nothing human was alien or uninteresting. Taking men and women as he found them, and conversing casually, as it appeared, on the topic which chanced to interest his hearer, he had not gone far before he had unmasked some vain pretence, cut folly to the quick, or raised some doubt of wide significance. And, though he often ended with negation, his negative achievements had a positive aim. For there underlay the process even when most ironical the conviction, not less profound because implicit, that in spite of false appearances, in spite of error, there are realities not undiscoverable, and whatsoever is real is good. His hearers had been confused by contradictory voices,—one crying "All is motion," another "All is rest"; one "The absolute is unattainable," another "The relative alone is real"; some upholding a vague sentiment of traditional right, while some declared for arbitrary convention and some for the "law of nature." Some held that virtue was spontaneous, some that it was due to training, and some paradoxically denied that either vice or falsehood had any meaning. The faith of Socrates, whether instinctive or inspired, remained untroubled by these jarring tones. He did not ask—"Is virtue a reality?" or "Is goodness a delusion?" But, with perfect confidence that there was an answer, he asked himself and others "What is it?" (*τί ἐστι*); or, more particularly, as Xenophon testifies, "What is a state? What is a statesman? What is just? What is unjust?"

What is government? What is it to be a ruler of men?" In this form of question, however simple, the originality of Socrates is typified; and by means of it he laid the first stone, not only of the fabric of ethical philosophy, but of scientific method. The secret of his success lay in the combination of a deep sense of human ignorance with a confidence not less deep in the power of reason.

The first result, and, as the Platonic Socrates declares, the only result he had obtained, was the consciousness of knowing nothing. But he who knows that he knows nothing is disposed to seek, and only those who seek will find. And the seeking mind attains, if not to knowledge, yet to a new standard of knowing. So long as results are contradictory, so long as negative instances are successfully applied, the searcher may make progress but is still to seek. For the aim of inquiry is the universal.

Human life and experience the sphere of search; truth and good, regarded as identical, the end of it; universality the test of reality, conversation the method, rational thought the means,—these are the chief notes of the dialectic of Socrates. Applying the native strength of his intelligence directly to the facts of life, he revealed their significance in countless ways, by unthought-of generalizations, by strange analogies, combining what men had not combined, distinguishing what they had not distinguished,—but always with the single aim of rousing them to the search after eternal truth and good.

The spirit which led on towards this unseen goal was not less practical than speculative. Socrates desired not only that men might know, but that they might know and do. Utility is the watchword no less of the Socratic than of the Baconian induction. But Socrates never doubted that if men once know they will also do. His own conscious conviction of the unity of truth and good he believed to be unconsciously the basis of all men's actions. They erred, he thought, from not seeing the good, and not because they would not follow it if seen. This is expressed in the Socratic *dicta*, "Vice is ignorance," "Virtue is knowledge." Men therefore must be brought to see the good and true, and that they may see it they must first be made aware that they do not see.

This lifelong work of Socrates, in which the germs of ethics, psychology, and logic were contained,—after it had been sealed by the death in which he characteristically at once obeyed his countrymen and convinced them of error,—was idealized, developed, dramatized—first embodied and then extended beyond its original scope—in the writings of Plato, which may be described as the literary outcome of the profound impression made by Socrates upon his greatest follower.

These writings (in pursuance of the importance given by Socrates to conversation) are all cast in the form of imaginary dialogue. But in those which are presumably the latest in order of composition this imaginative form interferes but little with the direct expression of the philosopher's own thoughts. The many-coloured veil at first inseparable from the features is gradually worn thinner, and at last becomes almost imperceptible.

Little more will be attempted in the following pages than to give a general outline of these immortal works in the order which is on the whole most probable, omitting those whose claim to authenticity is weakest, and passing lightly over some which, although genuine, are less important than the rest, or have less to do with the main current of Plato's thought.

The Platonic dialogues are not merely the embodiment of the mind of Socrates and of the reflexions of Plato. They are the portraiture of the highest intellectual life of Hellas in the time of Plato,—a life but distantly related to

<sup>1</sup> See Caird, *Hegel*, p. 168.

military and political events, and scarcely interrupted by them. Athens appears as the centre of the excitable Hellenic mind, profoundly stirred by the arrival of great sophists,<sup>1</sup> and keenly alive to the questions of Socrates, although in the pages of Plato, even more than in reality, he only "whispers with a few striplings in a corner." For, in the Platonic grouping, the agora, which was the chief scene of action for the real Socrates, retires into the background, and he is principally seen consorting with his chosen companions, who are also friends of Plato, and with the acquaintances whom he makes through them. The scene is narrowed (for the Academy was remote from the bustle of resort, and Plato judged the Hellenic world securely from the vantage-ground of partial retirement)—but the figures are distinct and full of life. In reading the dialogues, we not only breathe the most refined intellectual atmosphere, but are also present witnesses of the urbanity, the freedom, the playfulness, the generous warmth of the "best society" in Athens. For Plato has a numerous repertory of *dramatis personæ*, who stand in various relations to his chief character—the impetuous Chærephon, Apollodorus the inseparable weak brother, old Crito the true-hearted, Phædo the beloved disciple, Simmias and Cebes, who have been with Philolaus, the graceful and ingenuous Phædrus, the petulant Philebus, Theætetus of the philosophic nature, who is cut off in his prime, and the incorrigible Alcibiades; then Plato's own kinsmen—Glaucôn the irrepressible in politics, in quarrel, and in love, Adimantus, solid and grave, Critias in his phase of amateur philosopher, and not as what he afterwards became, Charmides, not in fiery manhood, but in his first bloom of diffident youth; and many others who appear as mere acquaintances, but have an interest of their own—the accomplished Agathon, the gay Aristophanes, Eryximachus the all-worthy physician, Meno, light of spirit, Callias, entertainer of sophists, Callicles the wilful man of the world, Cephalus the aged father of Lysis, and Nicias the honoured soldier. All these appear, not as some of them do on the page of history, in sanguinary contention or fierce rivalry, but as peaceful Athenians, in momentary contact with Socrates, whose electric touch now benumbs and now exhilarates, and sometimes goads to frenzy of love or anger. Still more distantly related to him, as it were standing in an outer circle, are the imposing forms of Gorgias and Protagoras, surrounded with the lesser lights of Hippias, Prodicus, and Polus. Thrasyarchus, Euthydemus, Dionysodorus hang round like comic masks, adding piquancy to the design. The adversaries Anytus and Meletus are allowed to appear for a moment, but soon vanish. The older philosophers, though Socrates turned away from them, also make their entrance on the Platonic stage. Parmenides with his magnificent depth is made to converse with the imaginary Socrates, who is still quite young. A stranger from Elea plays an important part in some later dialogues, and Timæus the Pythagorean is introduced discoursing of the creation of the world. In these dialogues Socrates is mostly silent; in the *Philebus* he has lost himself in Plato; and in the twelve books of the *Laws*, where an unnamed Athenian is the chief speaker, even the Platonic Socrates finally disappears.

Now, in evolving his philosophy from the Socratic basis, Plato works along three main lines,—the ethical and political, the metaphysical or scientific, and the mystical. All three are often intimately blended, as in the close of *Rep.*, bk. vi., and even where one element is uppermost the others are not wholly suppressed. But this distinction, like that sometimes made in modern philo-

sophy between the good, the true, and the beautiful, is one which, if not unduly pressed, may be usefully borne in mind. Having noted this once for all, we pass to the more detailed consideration of the several dialogues.

I. *Laches, Charmides, Lysis*.—In this first group Socrates is dealing tentatively with single ethical notions. The result in each case is a confession of ignorance, but the subject has been so handled as to point the way to more fruitful discussions in the future. And suggestions are casually thrown out which anticipate some of the most far-reaching of Plato's subsequent contemplations.

The *Laches* is a vigorous sketch, in which the characters *Laches* of the soldier, the aged citizen, and the prudent general are well preserved; and Socrates is seen conversing with his elders, although with reference to the treatment of the young. The question raised is the definition of courage; and the humour of the piece consists in showing that three men, all of whom are unquestionably brave, are unable to give an account of bravery, or to decide whether courage is an animal instinct or a mental accomplishment.

Similarly, in the dialogue which bears his name, the Char-temperate Charmides, of whom all testify that (as Aristophanes has it<sup>2</sup>) he "fills up the gracious mould of modesty," is hopelessly embarrassed when challenged by the Socratic method to put in words his conception of the modesty or temperance which he possesses, and which, as Socrates assures him, is a priceless gift. The *Charmides* contains some hints of Platonic notions, such as that of knowledge as self-consciousness, and of virtue as "doing one's own business."

The graceful little dialogue which bears the name of *Lysis*. *Lysis* ends, like the two former, with a confession of failure. Socrates, Lysis, and Menexenus are all friends, and think highly of friendship, yet after many efforts they are unable to tell "what friendship is." Yet some of the suggestions which are here laid aside are afterwards allowed to reappear. The notion that "what is neither good nor evil loves the good because of the presence of evil" is expanded and emphasized in the *Symposium*. And the conception of an ideal object of friendship, an *αὐτὸ φίλον* (though rejected as in the criticism of Aristotle by the characteristic *reductio ad infinitum*), is destined to have a wider scope in the history of Platonism.

II. *Protagoras, Io, Meno*.—The previous dialogues have marked the distinction between unconscious and conscious morality, and have also brought out the Socratic tendency to identify virtue with the knowledge of good. Now, the more strongly it is felt that knowledge is inseparable from virtue the more strange and doubtful appears such unconscious excellence as that of Laches, Charmides, or Lysis. Hence arises the further paradox of Socrates,—“Virtue is not taught, and that which is commonly regarded as virtue springs up spontaneously or is received unconsciously by a kind of inspiration.”

Protagoras, in the dialogue named after him, is the Protagoras professor of popular, unscientific, self-complacent excellence; while Socrates appears in his life-long search after the ideal knowledge of the best. The two men are naturally at cross purposes. Protagoras contends that virtue is taught by himself and others more or less successfully, and is not one but many. Socrates disputes the possibility of teaching virtue (since all men equally profess it, and even statesmen fail to give it to their sons), but affirms that, if it can be taught, virtue is not many, but one. The discussion, as in the former dialogues, ends inconclusively. But in the course of it Plato vividly sets forth the natural opposition between the empiric and scientific points of view, between a conventional and an

<sup>1</sup> It had been part of the policy of Pericles to draw distinguished foreigners to Athens.

<sup>2</sup> *Nub.*, 995, τῆς αἰδοῦς μέλλεις τῶν ἀγαθῶν ἀναπλήσαι.

intellectual standard. He does full justice to the thesis of Protagoras, and it is not to be supposed that he was contented to remain in the attitude which he has here attributed to Socrates. In his ideal state, where the earlier training of the best citizens is a refinement on the actual Hellenic education, he has to some extent reconciled the conceptions which are here dramatically opposed.

The preparations for the encounter and the description of it include many life-like touches,—such as the eagerness of the young Athenian gentleman to hear the sophist, though he would be ashamed to be thought a sophist himself; the confusion into which the house of Callias has been thrown by the crowd of strangers and by the self-importance of rival professors; the graceful dignity of the man who has been forty years a teacher, the graphic description of the whole scene, the characteristic speeches of Prodicus and Hippias (from which some critics have elicited a theory of their doctrines), and the continued irony with which Socrates bears them all in hand and soothes the great man after disconcerting him.

In the argument there are two points which chiefly deserve notice. (1) Protagoras, in accordance with his relative view of things (which Plato afterwards criticized in the *Theaetetus*), claims not to give men principles but to improve them in those virtues which Providence has given in some measure to all civilized men. (2) Socrates in postulating a scientific principle, which he expressly reserves for future consideration, would have it tested by the power of calculating the amount of pleasure. Grote dwells with some complacency on the "utilitarianism" of Socrates in the *Protagoras*. And it is true that a principle of utility is here opposed to conventional sentiment. But this opposition is intended to prepare the way for the wider and deeper contrast between an arbitrary and a scientific standard, or between impressions and conceptions or ideas. And when Plato (in the *Gorgias* and *Philebus*) endeavours to define the art of measurement, which is here anticipated, it is not wonderful that differences here unthought of should come into view, or that the pleasant should be again contradistinguished from the good. In all three dialogues he is equally asserting the supremacy of reason.

**Inspiration.** On the first vision of that transcendental knowledge<sup>1</sup> which is to be the key at once to truth and good, philosophy is apt to lose her balance, and to look with scorn upon "the trivial round, the common task," and the respectable common-places of "ordinary thinking." Yet, as Socrates is reminded by Protagoras, this unconscious wisdom also has a value. And Plato, who, when most ideal, ever strives to keep touch with experience, is fully convinced of the reality of this lower truth, of this unphilosophic virtue. But he is long puzzled how to conceive of it. For, if knowledge is all in all, what are we to make of wisdom and goodness in those who do not know? Protagoras had boldly spoken of honour and right as a direct gift from Zeus, and Socrates, in the *Io* and *Meno*, is represented as adopting an hypothesis of inspiration in order to account for these unaccredited graces of the soul.

**Io.** Socrates has observed that rhapsodists and even poets have no definite knowledge of the things which they so powerfully represent (comp. *Apol.*, 22; *Phaed.*, 245 A; *Rep.*, iii. 398 A). He brings the rhapsode *Io* to admit this, and to conclude that he is the inspired medium of a magnetic influence. The Muse is the chief magnet, and the poet is the first of a series of magnetic rings. Then follow the rhapsode and the actor, who are rings of inferior power, and the last ring is the hearer or spectator.

**Meno.** The *Meno* raises again the more serious question, Can

virtue be taught? Socrates here states explicitly the paradox with which the *Protagoras* ended. "Virtue is knowledge; therefore virtue can be taught. But virtue is not taught. Therefore (in the highest sense) there can be no virtue." And he repeats several of his former reasons,—that Athenian statesmen failed to teach their sons, and that the education given by sophists is unsatisfying. (The sophists are here denounced by Anytus, who is angered by Socrates's ironical praise of them.) But the paradox is softened in two ways:—(1) the absence of knowledge does not preclude inquiry, and (2), though virtue cannot be taught, yet there is a sense in which virtue exists.

1. Meno begins in gaiety of heart to define virtue, but is soon "benumbed" by the "torpedo" shock of Socrates, and asks "How can one inquire about that which he does not know?" Socrates meets this "eristic" difficulty with the doctrine of reminiscence (*ἀνάμνησις*). All knowledge is latent in the mind from birth and through kindred (or association) of ideas much may be recovered, if only a beginning is made. Pindar and other poets have said that the soul is immortal and that she has passed through many previous states.<sup>2</sup> And Socrates now gives a practical illustration of the truth that knowledge is evolved from ignorance. He elicits, from a Greek slave of Meno's, the demonstration of a geometrical theorem.<sup>3</sup> About the middle of the process he turns to Meno and observes that the slave (who has made a false start) is now becoming conscious of ignorance. He then gradually draws from the man, by leading questions, the positive proof.

2. Though virtue is not yet defined, it may be affirmed "hypothetically" that, if virtue is knowledge, virtue can be taught. And experience leads us to admit two phases of virtue—the one a mode of life based on scientific principle, which hitherto is an ideal only; the other sporadic, springing of itself, yet of divine origin, relying upon true opinion, which it is, however, unable to make fast through demonstration of the cause or reason. But, if there were a virtuous man who could teach virtue, he would stand amongst his fellows like Tiresias amongst the shades.<sup>4</sup>

This mystical account of ordinary morality is in keeping with the semi-mythical defence of the process of inquiry—that all knowledge is implicit in the mind from birth.

**III. Euthyphro, Apologia, Crito, Phaedo.**—There is no ground for supposing that these four dialogues were written consecutively, or that they belong strictly to the same period of Plato's industry. But they are linked together for the reader by their common reference to the trial and death of Socrates; no one of them has been proved to be in the author's earliest or latest manner; and they may therefore fitly end the series of dialogues in which the personal traits of the historic Socrates are most apparent, and Plato's own peculiar doctrines are as yet but partially disclosed.

The little dialogue known by the name of *Euthyphro* might have been classed with the *Laches*, *Charmides*, and *Lysis*, as dealing inconclusively with a single notion. But, although slight and tentative in form, it has an undertone of deeper significance, in keeping with the gravity of the occasion. Plato implies that Socrates had thought more deeply on the nature of piety than his accusers had, and also that his piety was of a higher mood than that of ordinary religious men.

Euthyphro is a soothsayer, well-disposed to Socrates, but not one of his particular friends. They meet at the

<sup>2</sup> The origin of this traditional belief is very obscure. The Greeks themselves were apt to associate it with Pythagoras and with the "Orphic" mysteries.

<sup>3</sup> *Euc.*, i. 47 (the case where the triangle is isosceles).

<sup>4</sup> *Hom.*, *Odys.*, x. 495, *ὄψ' ἀνθρώπων, καὶ δὲ σὺ καὶ ἀΐσσουαι*.

<sup>1</sup> *Phaed.*, 82 B; *Rep.*, x. 619 C.

door of the king archon, whither Socrates has been summoned for the "precognition" (*ἀνάκρισις*) preliminary to his trial. Both men are interested in cases of alleged impiety. For Euthyphro's business is to impeach his father, who has inadvertently caused the death of a criminal labourer. The prophet feels the duty of purging the stain of blood to be more imperative the nearer home. Socrates is struck by the strong opinion thus evinced respecting the nature of piety, and detains Euthyphro at the entrance of the court, that he may learn from so clear an authority "what piety is," and so be fortified against Meletus. He leads his respondent from point to point, until the doubt is raised whether God loves holiness because it is holy, or it is holy because loved by God. Does God will what is righteous, or is that righteous which is willed by God? Here they find themselves wandering round and round. Socrates proves himself an involuntary Dædalus who makes opinions move, while he seeks for one which he can "bind fast with reason."

"The holy is a portion of the just." But what portion? "Due service of the gods by prayer and sacrifice." But how does this affect the gods? "It pleases them." Again we are found to be reasoning in a circle.

"Thus far has Socrates proceeded in placing religion on a moral foundation. He is seeking to realize the harmony of religion and morality, which the great poets Æschylus, Sophocles, and Pindar had unconsciously anticipated, and which is the universal want of all men. To this the soothsayer adds the ceremonial element, 'attending upon the gods.' When further interrogated by Socrates as to the nature of this 'attention to the gods,' he replies that piety is an affair of business, a science of giving and asking and the like. Socrates points out the anthropomorphism of these notions. But when we expect him to go on and show that the true service of the gods is the service of the spirit and co-operation with them in all things true and good, he stops short; this was a lesson which the soothsayer could not have been made to understand, and which every one must learn for himself."

*Apology.* In Plato's *Apology* the fate of Socrates is no longer the subject of mere allusions, such as the rage of Anytus at the end of the *Meno*, and the scene and occasion of the *Euthyphro*. He is now seen face to face with his accusers, and with his countrymen who are condemning him to death.

What most aggravated his danger (after life-long impunity) is thus stated by Mr James Riddell, in the introduction to his edition of the dialogue:—"The *ἐπιείκεια*" (clemency) "of the restored people did not last long, and was naturally succeeded by a sensitive and fanatical zeal for their revived political institutions. Inquiry into the foundations of civil society was obviously rather perilous for the inquirer at such a time. Socrates knew the full extent of his danger. But, according to Xenophon (*Mem.*, iv. c. 8, § 14), he prepared no defence, alleging that his whole life had been a preparation for that hour."

The tone of the Platonic *Apology* is in full accordance with that saying; but it is too elaborate a work of art to be taken literally as a report of what was actually said. Professor Jowett well compares it to "those speeches of Thucydides in which he has embodied his conception of the lofty character and policy of the great Pericles." Yet "it is significant that Plato is said to have been present at the defence, as he is also said to have been absent at the last scene of the *Phædo*. Some of the topics may have been actually used by Socrates, and the recollection of his very words may have rung in the ears of his disciple."

The Platonic *Apology* is in three parts:—(1) before conviction, (2) after conviction and before sentence, (3) after the sentence. 1. Socrates cares not for acquittal. But he does care to explain his life. And he selects those aspects of it which there is hope of making his audience understand. That he partly succeeded in this is shown by the large number of those (220 out of 500) who voted for his acquittal.

<sup>1</sup> Jowett.

a. His answer to Meletus, as least important, is reserved for the middle of his speech. He addresses himself first to "other accusers,"—comic poets and the rest, who have prejudiced his reputation by falsely identifying him with the physical philosophers and the sophists. But what then is the strange pursuit which has given to Socrates the name of wise? It is the practice of cross-examining, to which he was first impelled by the oracle at Delphi, and which he has followed ever since as a religious mission. The god said "Socrates is wise," when he was conscious of no wisdom great or small. So he went in search of some one wiser than himself, but could find none, though he found many who had conceit of wisdom. And he inferred that the god must mean "He is wisest who, like Socrates, is most aware of his own ignorance." This unceasing quest has left him in great poverty, and has made him enemies, who are represented by Anytus, Meletus, and Lycon. And their enmity is further embittered by the pleasure which young men take in seeing pretence unmasked, and in imitating the process of refutation. Hence has arisen the false charge that Socrates is a corrupter of youth.

b. Here he turns to Meletus. "If I corrupt the youth, who does them good?" *Meletus*. "The laws, the judges, the audience, the Athenians generally" (comp. *Protagoras* and *Meno*). "Strange, that here only should be one to corrupt and many to improve; or that any one should be so infatuated as to wish to have bad neighbours." *Meletus*. "Socrates is an atheist. He believes the sun to be a stone." "You are accusing Anaxagoras. I have said that I know nothing of such theories. And you accuse me of introducing novel notions about divine things. How can I believe in divine things (*δαίμονια*) and not in divine beings (*δαίμονες*)? and how in divine beings, if not in gods who are their authors?"

c. That is a sufficient answer for his present accuser. He returns to the general long-standing defamation, which may well be his death, as slander has often been and again will be the death of many a man.

Yet if spared he will continue the same course of life, in spite of the danger. As at Potidæa and Delium he faced death where the Athenians posted him, so now he will remain at the post where he is stationed by the god. For to fear death is to assume pretended knowledge.

One thing is certain. A worse man cannot harm a better. But if the Athenians kill Socrates, they will harm themselves. For they will lose the stimulus of his exhortations;—and his poverty is a sufficient witness that he was sincere. Not that he would engage in politics. If he had done that he would have perished long before,<sup>2</sup> as he nearly did for his independent vote after the battle of Arginusæ, and for disobeying the murderous command of the thirty tyrants.

But have not Socrates's disciples, Alcibiades, Critias, Charmides, proved bad citizens? He has no disciples. Any one, bad or good, may come and hear him, and the talk which is his life-work is not unamusing. But why are no witnesses brought to substantiate this charge? There are elder friends of his companions, who would be angry if he had used his influence for harm. But these men's confidence in Socrates is unshaken.

He will not appeal *ad misericordiam*. That would be a disgrace for one who (rightly or not) has been reputed wise, and to admit such an appeal in any case is a violation of the juror's oath.

Socrates has told the Athenians the whole truth, so far as a mixed audience of them could receive it. Elaboration and subtlety could have no place in addressing the Heliastic court, nor could that universal truth towards which he was leading men be made intelligible to a new audience while the *elepsydra* was running. But his tone and attitude must have made a strong appeal to the better nature of his hearers. With Meletus he "played rather than fought," but he has shown clearly that he has no fear of death, that he chooses to obey God rather than man, and that for very love of the Athenians he will not be swayed by their desires.

2. One convicted on a capital charge had the right of pleading before sentence in mitigation of the penalty proposed by his accuser. Socrates was convicted by fewer votes than he himself anticipated. The indictment of Meletus was ineffectual, and if it had not been for the speeches of Anytus and Lycon the defendant would have been triumphantly acquitted. Could he but have conversed with his judges more than once, he might have removed their prejudices. In no spirit of bravado, therefore, but in simple justice to himself, he meets the claim of Meletus that he shall be punished with death by the counter claim that he shall be maintained in the prytaneum as a public benefactor. He cannot ask that death, which may be a good, shall be commuted for imprisonment or exile, which are certainly evils. A fine would be no evil: but he has no money;—he can offer a mina. Here Plato and others interpose, and with their friendly help he offers thirty minæ.

3. He is sentenced to death, and the public business of the court

<sup>2</sup> Comp. *Gorg.*, 521; *Rep.*, vi. 496.

is ended. But, while the record is being entered and the magistrates are thus occupied, Socrates is imagined as addressing (a) the majority, and (3) the minority in the court.

a. To those who have condemned him he speaks in a prophetic tone. "For the sake of depriving an old man of the last days of life, they have given Athens a bad name. He would not run away, and so death has overtaken him. But his excesses are overtaken by unrighteousness, and must reap the fruits of it."

"Nor will the Athenians find the desired relief. Other reprovers, whom Socrates has hitherto restrained, will now arise, not in a friendly but in a hostile spirit. The only way for the citizens to escape reproach is to reform their lives."

b. To the minority, who would have acquitted him, he speaks with gentle solemnity. "Let them know to their comfort that the divine voice has not once checked him throughout that day. This indicates that death is not an evil. And reason shows that death is either a long untroubled sleep, or removal to a better world, where are no unjust judges."

"No evil can happen to a good man either in life or after death. Wherefore Socrates will not be angry with his condemners, who have done him no harm, although they meant him anything but good. He will only ask of them to do to the sons of Socrates as Socrates has done to them."

Crito.

Is the love of truth consistent with civic duties? Is the philosopher a good citizen? are questions which are sure to arise where the truth involves practical improvement. In the *Apology* Socrates appears as an intrepid reformer; the *Crito* gives an impressive picture of him as a loyal and law-abiding Athenian.

Execution had been delayed, during the annual mission to Delos (during which no one could be put to death). But the returning vessel had just been reported as departed from Sunium. At early dawn Crito, the oldest friend of Socrates, obtained access to his cell, and found him sleeping peacefully. Presently he awoke, and Crito told him of the approach of the fatal ship. Socrates replies by telling his dream. A fair form stood over him and said,

"The third day hence to Phæbus such thou comest."

And it would seem that the day after to-morrow will really be the day for going home.

Crito then reveals his plan for an escape. And Socrates argues the question in the old familiar way. "Crito's zeal is excellent, and most men would think his object right. But the few who think soundly say that it is wrong to return evil for evil. The laws of Athens (through the fault of men) are doing Socrates harm. But ought he therefore to infringe the law? Might not the laws of his country plead with him and say:—'You owe to us your birth and breeding; and when grown up you voluntarily submitted to us. For you might have gone elsewhere. But you preferred us to all other laws, and have been the most constant resident in Athens. Even at the last you accepted death rather than exile. If you now break your covenant, you will ruin your friends and will be rejected by all well-ordered cities. You might be received in Thessaly, but could only live there by cringing to foreigners for food. Where in that case will be your talk about virtue? You would not take your sons thither. And your friends would be equally kind to them if you were dead.'"

"Think not of life and children first and of justice afterwards, but think of justice first, that you may be justified in the world below." Crito admits these arguments to be unanswerable.

Phædo.

The *Meno* referred to the immortality and pre-existence of the soul as a traditional doctrine, and it was there associated with the possibility of inquiry. In the *Phædo* Plato undertakes to substantiate this belief and base it anew, by narrating the last hours of Socrates, who is represented as calmly discussing the question with his friends when his own death was immediately at hand. The argument turns chiefly on the eternity of knowledge, and is far from satisfying. For, granting that eternity of knowledge involves eternity of mind, does the eternity of mind assure continued being to the individual? Yet so unprejudiced reader of the *Phædo* can doubt that Plato, at the time of writing it, sincerely believed in a conscious personal existence after death. The words of Socrates, when he declares his hope of going to be with other friends, are absolutely unambiguous, and his reply to Crito's question, "How shall we bury you?" has a convincing

<sup>1</sup> In the *Timæus* immortality is made to rest on the goodwill of God, because "only an evil being would wish to dissolve that which is harmonious and happy" (*Timæus*, 41 A).

force beyond all dialectic:—"I cannot persuade Crito that I here am Socrates—I who am now reasoning and ordering discourse. He imagines Socrates to be that other, whom he will see by and by, a corpse." This and similar touches not only stamp the *Phædo* as a marvel of art, but are indisputable evidences of the writer's profound belief. They may be inventions, but they have nothing "mythical" about them, any more than the charge of Socrates to his friends that they would best fulfil his wishes by attending to their own lives.

The narrative, to be appreciated, must be read in full. But a short abstract of the argument may be given here.

1. Death is merely the separation of soul and body. And this is the very consummation at which philosophy aims. The body hinders thought. The mind attains to truth by retiring into herself. Through no bodily sense does she perceive justice, beauty, goodness, and other ideas. The philosopher has a life-long quarrel with bodily desires, and he should welcome the release of his soul. Thus he alone can have true courage, even as temperance and all the virtues are real in him alone.

But does the soul exist after death?

a. An old tradition tells of many successive births, the soul departing to Hades and returning again, so that the living are born from the dead. And if the dead had no existence, this could not be, since from nothing nothing can arise. Moreover, experience shows that opposite states come from their opposites, and that such a process is always reciprocal. Death certainly succeeds to life. Then life must succeed to death. And that which undergoes these changes must exist through all. If the dead came from the living, and not the living from the dead, the universe would ultimately be consumed in death.

This presumption is confirmed by the doctrine (here attributed to Socrates, comp. *Meno*), that knowledge comes through recollection. What is recollected must be previously known. Now we have never since birth had intuition of the absolute equality of which (through association) we are reminded by the sight of things approximately equal. And we cannot have seen it at the moment of birth, for at what other moment can we have forgotten it? Therefore, if ideas be not vain, our souls must have existed before birth, and, according to the doctrine of opposites above stated, will have continued existence after death.

b. To charm away the fears of the "child within," Socrates adds, as further considerations:—

(1) The soul is uncompounded, incorporeal, invisible, and therefore indissoluble and immovable.

(2) The soul commands, the body serves; therefore the soul is akin to the divine.

(3) Yet even the body holds together long after death, and the bones are all but indestructible.

The soul, if pure, departs to the invisible world, but, if tainted by communion with the body, she lingers hovering near the earth, and is afterwards torn into the likeness of some lower form. That which true philosophy has purified alone rises ultimately to the gods. This lesson is impressively applied.

2. A pause ensues; and Simmias and Cebes are invited to express their doubts. For, as the swan dies singing, Socrates would die discoursing.

a. Simmias desires not to rest short of demonstration, though he is willing to make the highest attainable probability the guide of life.

If the soul is the harmony of the body, what becomes of her "when the lute is broken"?

b. Cebes compares the body to a garment which the soul keeps wearing at. The garment in which the weaver dies outlasts him. So the soul may have woven and worn many bodies in one lifetime, yet may perish and leave a body behind. Or even supposing her to have many lives, does even this hypothesis exempt her from ultimate decay?

Socrates warns his friends against losing faith in inquiry. Theories, like men, are disappointing; yet we should be neither misanthropists nor misogynists. Then he answers his two friends.

(a) (1) The soul is acknowledged to be prior to the body. But no harmony is prior to the elements which are harmonized.

(2) The soul has virtue and vice, i.e., harmony and discord. Is there harmony of harmony? Comp. *Epp.*, x. 602.

(3) All soul is equally soul, but all harmony is not equally harmonious.

(4) If the soul were the harmony of the body, they would be agreed; but, as has been already shown, they are perpetually quarrelling.

(5) The soul is not conditioned by the bodily elements, but has the power of controlling them.

(6) Cebes has raised the wide question whether the soul is independent of generation and corruption. Socrates owns that he him-

self (*i.e.*, Plato?) had once been fascinated by natural philosophy, and had sought to give a physical account of everything. Then, hearing out of Anaxagoras that mind was the disposer of all, he had hoped to learn not only how things were, but also why. But he found Anaxagoras forsaking his own first principle and jumbling causes with conditions. ("The cause why Socrates sits here is not a certain disposition of joints and sinews, but that he has thought best to undergo his sentence,—else the joints and sinews would have been ere this, by Crito's advice, on the way to Thessaly.") Physical science never thinks of a power which orders everything for good, but expects to find another Atlas to sustain the world more strong and lasting than the reason of the best.

Socrates had turned from such philosophers and found for himself a way, not to gaze directly on the universal reason, but to seek an image of it in the world of mind, wherein are reflected the ideas, as, for example, the idea of beauty, through partaking of which beautiful things are beautiful. Assuming the existence of the ideas, he felt his way from hypothesis to hypothesis.

Now the participation of objects in ideas is in some cases essential and inseparable. Snow is essentially cold, fire hot, three odd, two even. And things thus essentially opposite are exclusive of each other's attributes. (When it was said above that opposites come from opposites, not opposite things were meant, but opposite states or conditions of one thing.) Snow cannot admit heat, nor fire cold; for they are inseparable vehicles of heat and cold respectively. The soul is the inseparable vehicle of life, and therefore, by parity of reasoning, the soul cannot admit of death, but is immortal and imperishable.

3. What follows is in the true sense *mythological*, and is admitted by Socrates to be uncertain.—"Howbeit, since the soul is proved to be immortal, men ought to charm their spirits with such tales."

The earth, a globe self-balanced in the midst of space, has many mansions for the soul,<sup>1</sup> some higher and brighter, some lower and darker than our present habitation. We who dwell about the Mediterranean Sea are like frogs at the bottom of a pool. In some higher place, under the true heaven, our souls may dwell hereafter, and see not only colours and forms in their ideal purity but truth and justice as they are.

In the *Phædo*, more than elsewhere, Plato preaches withdrawal from the world. The Delian solemnity is to Socrates and his friends a period of "retreat," in which their eyes are turned from earthly things to dwell on the eternal. The theory of ideas here assumes its most transcendental aspect, and it is from portions of this dialogue and of the *Phædrus* and *Timæus* that the popular conception of Platonism has been principally derived. But to understand Plato rightly it is not enough to study isolated passages which happen to charm the imagination; nor should single expressions be interpreted without regard to the manner in which he presents the truth elsewhere.

It has already been shown (1) that Socratic inquiry implied a standard of truth and good, undiscovered but endlessly discoverable, and to be approached inductively; and (2) that in Plato this implicit assumption becomes explicit, in the identification of virtue with knowledge (*Lach.*, *Charm.*) as an art of measurement (*Protag.*), and in the vision (towards the end of the *Lysis*) of an absolute object of desire. The Socratic "self-knowledge" has been developed (*Charm.*) into a science of mind or consciousness, apart from which no physical studies can be fruitful. (3) Co-ordinate with these theoretical tendencies there has appeared in Plato the determination not to break with experience.—The bearing of these remarks on the further progress of Plato's thoughts will appear in the sequel. Meanwhile, in the *Phædo*, a long step is made in the direction of pure idealism. The ordinary virtue, which in the *Protagoras* and *Meno* was questioned but not condemned, is here rejected as unreal, and the task proposed to the philosopher is less to understand the world than to escape from it. The universal has assumed the form of the ideal, which is supposed, as elsewhere in Plato, to include

mathematical as well as moral notions.<sup>1</sup> The only function of perception is to awaken in us some reminiscence of this ideal. By following the clue thus given, and by searching for clearer images of truth in the world of mind, we may hope to be emancipated from sensation, and to lay hold upon the sole object of pure reason.

It is obvious that when he wrote the *Phædo* Plato conceived of universals as objective entities rather than as forms of thought. The notion of "ideal colours" (though occurring in the myth) is an indication of his ontological mood.

Yet even here the εἶδη are not consistently hypostatized. The notion of "what is best" has a distinctly practical side, and the "knowledge through reminiscence" is in one aspect a process of reflexion on experience, turning on the laws of association.<sup>2</sup> It is also said that objects "partake" of the ideas, and some concrete natures are regarded as embodiments or vehicles of some of them. Still, if taken as a whole, notwithstanding the scientific attitude of Socrates, the *Phædo* is rather a meditation than an inquiry,—a study of the soul as self-existent, and of the mind and truth as co-eternal.

IV. *Symposium*, *Phædrus*, *Cratylus*.—Socrates is again imagined as in the fulness of life. But the real Socrates is becoming more and more inextricably blended with Platonic thought and fancy. In the *Apology* there is a distinct echo of the voice of Socrates; the *Phædo* gives many personal traits of him; but the dialogues which are now to follow are replete with original invention, based in part, no doubt, on personal recollections.

The *Symposium* admits both of comparison and of contrast with the *Phædo*. Both dialogues are mystical, both are spiritual, but the spirituality in either is of a different order. That is here immanent which was there transcendent; the beautiful takes the place of the good. The world is not now to be annihilated, but rather transfigured, until particular objects are lost in universal light. Instead of flying from the region of growth and decay, the mind, through intercourse with beauty, is now the active cause of production. Yet the life of contemplation is still the highest life, and philosophy the truest *μουσική*.

The leading conception of the *Symposium* has been anticipated in the *Lysis*, where it was said that "the indifferent loves the good, because of the presence of evil."

The banqueters (including Socrates), who are met to celebrate the tragic victory of Agathon, happen not to be disposed for hard drinking. They send away the flute-girl and entertain each other with the praise of Love.

Phædrus tells how Love inspires to honourable deeds, and how Alcestis and Achilles died for Love.

Pausanias rhetorically distinguishes the earthly from the heavenly Love.

The physician Eryximachus, admitting the distinction, yet holds that Love pervades all nature, and that art consists in following the higher Love in each particular sphere. So Empedocles had spoken of Love as overcoming previous discord. For opposites cannot, as Heraclitus fancied, coexist.

Aristophanes, in a comic myth, describes the origin of Love as an imperfect creature's longing for completion. The original double human beings were growing impious, and Zeus split them in twain, ever since which act the bereaved halves wander in search of one another.

Agathon speaks, or rather sings, of Love and his works. He is the youngest, not the eldest of gods, living and moving delicately wherever bloom is and in the hearts of men,—the author of all virtue and of all good works, obeyed by gods, fair and causing all things fair, making men to be of one mind at feasts—pilot, defender, saviour, in whose footsteps all should follow, chanting strains of love.

Socrates will not attempt to rival the poet, and begins by stipulating that he may tell the truth. He accepts the distinction between Love and his works, but points out that, since desire implies want, and the desire of Love is toward beauty, Love, as wanting beauty, is not beautiful. So much being established in

<sup>1</sup> Comp. Milton, *Il Penseroso*, 88-92—

"To unsphere  
The spirit of Plato, to unfold  
What worlds or what vast regions hold  
The immortal mind that hath forsook  
Her mansion in this fleshly nook."

<sup>2</sup> Comp. *Theæt.*, 184-186.

the Socratic manner, he proceeds to unfold the mystery once revealed to him by Diotima, the Mantinean wise woman.

Love is neither beautiful nor ugly, neither wise nor foolish, neither god nor mortal. Between gods and mortals is the world of mediating spirits (τὰ δαιμόνια). And Love is a great spirit, child of Resource (the son of Prudence) and Poverty the beggar maid, who conceived him at the birthday feast of Aphrodite. He is far from living "delicately," but is ragged and shoeless, always in difficulties, yet always brimming with invention, a mighty hunter after wisdom and all things fair; sometimes "all full with feasting" on them, the next moment "clean starved" for lack; never absolutely knowing nor quite ignorant. That is to say, he is a "philosopher." For knowledge is the most beautiful thing, and love is of the beautiful.

But what does love desire of the beautiful? The possession is enough. But there is one kind of love—called "being in love"—which desires beauty for a peculiar end. The lover is seeking, not his "other half," but possession of the beautiful and *birth in beauty*.

For there is a season of puberty both in body and mind, when human nature longs to create, and it cannot save in presence of beauty. This yearning is the earnest of immortality. Even in the bird's devotion to its mate and to its young there is a craving after continued being. In individual lives there is a flux, not only of the body, but in the mind. Nay, the sciences themselves also come and go (here the contrast to the *Phædo* is at its height). But in mortal things the shadow of continuity is succession.

The love of fame is a somewhat brighter image of immortality than the love of offspring. Creative souls would bring into being not children of their body, but good deeds. And such a one is readiest to fall in love with a fair mind in a fair body, and then is filled with enthusiasm and begets noble thoughts. Homer, Hesiod, Lycurgus, Solon, were such genial minds. But they stopped at the threshold (comp. *Prot.*, *Meno*), and saw not the higher mysteries, which are reserved for those who rise from noble actions, institutions, laws, to universal beauty. The true order is to advance from one to all fair forms, then to fair practices, fair thoughts, and lastly to the single thought of absolute beauty. In that communion only, beholding beauty with the eye of the mind, one shall bring forth realities and become the friend of God and be immortal, if mortal man may.

Alcibiades here breaks in and is vociferously welcomed. He is crowning Agathon, when, on perceiving Socrates, he declares that he will crown him too. Then he announces himself king of the feast, and insists upon hard drinking (though this will make no difference to Socrates).

Eryximachus demands from the newcomer a speech in praise of love. But Alcibiades will praise no one else when Socrates is near. And with the freedom of one who is deep in wine he proceeds with his strange encomium of "this Marsyas."

"In face and outward bearing he is like a Satyr or Silenus, and by his voice he charms more powerfully than they do by their piping. The eloquence of Pericles has no effect in comparison with his. His words alone move Alcibiades to shame, and fascinate him until he stops his ears and runs from him."—"I often wish him dead. Yet that would break my heart. He brings me to my wit's end."—"And, as carved Sileni are made to encase images of gods, so this Silenus-mask entreasures things divine. He affects ignorance and susceptibility to beauty. Thus he mocks mankind. But he cares nothing for outward shows, and his temperance (σφραγιστήρ) is wonderful."

To prove this Alcibiades reveals his own heart-secret. (He is not ashamed to speak it amongst others who have felt the pang which Socrates inflicts.) And he makes it abundantly manifest that in their widely-rumoured intercourse (comp. *Protag.* init.) Socrates had never cared for anything but what was best for his younger friend. Alcibiades then relates as an eyewitness the endurance shown by Socrates at Potidæa, his strange persistence in solitary meditation,—standing absorbed in thought for a day and a night together,—and his intrepid conduct in the retreat from Delium (comp. *Laches*). "The talk of Socrates is of pack-asses and cobblers, and he is ever saying the same things in the same words; but one who lifts the mask and looks within will find that no other words have meaning." Alcibiades ends by warning his companions against the wiles of Socrates.

Some raillery follows, and they are invaded by another band of revellers, who compel them to drink still more deeply. The soberly inclined (led by Eryximachus) sink off, and Aristodemus, the reporter of the scene, only remembers further that when he awoke at cock-crow Socrates was still conversing with Agathon and Aristophanes, and showing them that tragedy and comedy were essentially one. He talked them both asleep, and at daybreak went about his usual business.

The philosopher of the *Symposium* is in the world and yet not of it, apparently yielding but really overcoming. In the *Phædo* the soul was exhorted to "live upon her servant's loss," as in Shakspeare's most religious sonnet;

this dialogue tells of a "soul within sense" in the spirit of some more recent poetry. By force of imagination rather than of reason, the reconciliation of becoming (γένεσις) with being (οὐσία), of the temporal with the eternal, is anticipated. But through the bright haze of fancy and behind the mask of irony, Socrates still appears the same strong, pure, upright, and beneficent human being as in the *Apology*, *Crito*, and *Phædo*.

The impassioned contemplation of the beautiful is again Phædrus. imagined as the beginning of philosophy. But the "limitless ocean of beauty" is replaced by a world of supramundane forms, beheld by unembodied souls, and remembered here on earth through enthusiasm, proceeding by dialectic from multiform impressions to one rational conception, and distinguishing the "lines and veins" of truth. The *Phædrus* records Plato's highest "hour of insight," when he willed the various tasks hereafter to be fulfilled. In it he soars to a pitch of contemplation from whence he takes a comprehensive and keen-eyed survey of the country to be explored, marking off the blind alleys and paths that lead astray, laying down the main lines and chief branches, and taking note of the erroneous wanderings of others. Reversing the vulgar adage, he flies that he may creep.

The transcendent aspiration of the *Phædo* and the mystic glow of the *Symposium* are here combined with the notion of a scientific process. No longer asking, as in the *Protagoras*, Is virtue one or many? Plato rises to the conception of a scientific one and many, to be contemplated through dialectic,—no barren abstraction, but a method of classification according to nature.

This method is to be applied especially to psychology, not merely with a speculative, but also with a practical aim. For the "birth in beauty" of the *Symposium* is here developed into an art of education, of which the true rhetoric is but the means, and true statesmanship an accidental outcome.

Like all imaginative critics, Plato falls to some extent under the influence of that which he criticizes. The art of rhetoric which he so often travestied had a lasting effect upon his style. Readers of his latest works are often reminded of the mock grandiloquence of the *Phædrus*. But in this dialogue the poetical side of his genius is at the height. Not only can he express or imitate anything, and produce any effect at will, but he is standing behind his creation and disposing it with the most perfect mastery, preserving unity amidst profuse variety, and giving harmony to a wildness bordering on the grotesque.

The person of Socrates is here deliberately modified. He no longer (as in the *Symposium*) teaches positive wisdom under the pretence of repeating what he has heard, but is himself caught by an exceptional inspiration, which is accounted for by the unusual circumstance of his finding himself in the country and alone with Phædrus. He has been hitherto a stranger to the woods and fields, which would tempt him away from studying himself through intercourse with men. But by the promise of discourse—especially of talk with Phædrus—he may be drawn anywhere.

Phædrus has been charmed by a discourse of Lysias, which after some coy excuses he consents to read.

It is a frigid erotic diatribe, in which one not in love pleads for preference over the lover. Socrates hints at criticism, and is challenged to produce something better on the same theme.

1. Distinguishing desire from true opinion, he defines love as desire prevailing against truth, and then expatiates on the harmful tendencies of love as so defined. But he becomes alarmed at his own unwonted eloquence, and is about to remove, when the "divine token" warns him that he must first recite a "palinode" in praise of love. For no divine power can be the cause of evil.

2. Love is madness; but there is a noble madness, as is shown by soothsayers (called μάντεις from μάωμαι). And of the higher madness there are four kinds.

To explain this it is necessary to understand psychology. The soul is self-existent and self-moving, and therefore eternal. And her form is like a pair of winged steeds with their charioteer. In divine souls both steeds are good, but in human souls one of them is bad. Now before entering the body the soul loses her wings, which in her unembodied state were nourished by beauty, wisdom, goodness, and all that is divine. For at the festival of souls, in which they visit the heaven that is above the heavens, the unruly steed causes the charioteer to see imperfectly. So the soul cast her feathers and fell down and passed into the human form. And, according to the comparative clearness or dimness of that first vision, her earthly lot is varied from that of a philosopher or artist down through nine grades (including woman) to that of a tyrant. On her conduct in this state of probation depends her condition when again born into the world. And only in ten thousand years can she return to her pristine state, except through a life of philosophy (comp. *Phaedo*) or of pure and noble love (comp. *Symposium*).

The mind of the philosopher alone has wings. He is ever being initiated into perfect mysteries, and his soul alone becomes complete. But the vulgar deem him mad and rebuke him; they do not see that he is inspired.

This divine madness (the fourth kind of those above mentioned) is kindled through the renewal of vision of beauty. For wisdom is not seen; her loveliness would have been transporting if she had a visible form. The struggle of the higher passion with the lower is then described with extraordinary vividness, under the image of the two steeds. When the higher impulse triumphs, the issue is a philosophic friendship, at once passionate and absolutely pure.

3. From his "palinode" Socrates returns to Lysis, who is advised to leave speech-writing for philosophy.

a. *Phaedrus* remarks that the speech-writer is despised by the politician. Socrates replies that speech-writing and politics are one concern. The real difference is between those who base their teaching on philosophy and those who are content with rules of art. For example, if the first speech of Socrates is compared with that of Lysis, the one is found to distinguish and define, the other not; the one observes order in discourse, the other "begins where he should end," and his utterance is like a disordered chain. A speech should be an organic whole, a "creature having hands and feet." So in the "palinode" there was a classification of the kinds of madness, which led the way to "a possibly true though partly erring myth."

This approximation to truth in the midst of much that was playful was due to the observance of two principles, generalization and division (*γενεσις, διαίρεσις*). Whoever sees the one and many in nature, like Socrates follows and walks in his footsteps, as if he were a god.

In comparison of dialectic, as thus conceived, the frigid rules of Lysis, Parmenides, Theodorus, Euthydemus, Tisias, Gorgias, Polus, and Protagoras are futile and absurd.

b. Another condition of teaching (or true rhetoric) is the science of mind. Whether the soul be one or many, complex or multiform, and if multiform what are its parts and kinds, are questions which the teacher must have already solved. And he must likewise have classified all arguments and know them in their various applicability to diverse souls. An art of speaking that should fulfil this condition is non-existent. Yet how can even verisimilitude be attained without knowledge of truth?

c. The art of writing is kindred to the art of speech. But Socrates maintains that oral teaching through the living contact of mind with mind has many advantages over written composition, which is, comparatively speaking, a dead thing. Men may write for amusement or to record the intercourse that has been. But the serious occupation of the true thinker and teacher is the communication of truth through vital converse with others like-minded,—the creation of "thoughts that breathe" in spirits conscious of their value.

In conclusion, a friendly hint is given to Isocrates that he may do better than Lysis if he will turn his attention to philosophy.

The *Phaedrus* anticipates much that Plato afterwards slowly elaborated, and retains some things which he at last eliminated. (1) The presence of movement or impulse in the highest region is an aspect of truth which reappears in the *Sophistes* and other later dialogues. It has been thought strange that it should be found so early as in the *Phaedrus*. But does not this remark imply an unwarrantable assumption, viz., that Plato's idealism took its departure from the being of Parmenides? Is it not rather the fact that his own theory was formulated before the Megarian ascendancy led him to examine the Eleatic doctrine, and that it was by a tendency from the first inherent in Platonism that that doctrine was modified

in his final teaching? (2) The outlines of method which are thrown out at white heat in the *Phaedrus* are a preparation for the more sober treatment of the ideas in the dialectical dialogues. In these, however, the conception of classification is somewhat altered through contact with Eleaticism. (3) The *Phaedrus* aims, not merely at realizing universals, but at grasping them in and through particulars. This is an ideal of knowledge which was "lost as soon as seen," but one which in some of his latest dialogues, such as the *Politicus* and *Philebus*, Plato again endeavours to work out. (4) The *Phaedrus* contains the elements of that true psychology into which the ontological theory of the ideas is gradually transmuted in Plato's more advanced writings, when the difficulties of his ideal doctrine in its cruder forms have been clearly felt and understood. (5) Plato here appears as a professor of education, preferring oral intercourse to authorship. In this paradox he at once exalts the work of Socrates and avows his own vocation as a teacher. The passage throws an interesting light upon the form of dialogue in which his works are cast. But it is not to be supposed that he remained long unconscious of the influence he was destined to wield by writing. In undertaking a great task like the *Republic*, he practically receded from the untenable view asserted here; and in the *Laws* he recommends his longest and most prosaic work as a suitable basis for the education of the future. (6) It must always appear strange, even to those most familiar with the conditions of Hellenic life, that in portraying the idealizing power of passionate love Plato should have taken his departure from unnatural feeling.

On this subject he has sung his own "palinode" in the *Laws*, which he intended as his final legacy to mankind.<sup>1</sup> Not that he ceased to exalt genius and originality above mere talent, or to demand for philosophy the service of the heart as well as the head, nor yet that friendship was less valued by him in later years. All this remained unchanged. And in the *Republic* the passion of love is still distantly referred to as the symbol of ideal aspiration. But a time came when he had learned to frown on the aberration of feeling which in the *Symposium* and *Phaedrus* he appears to regard as the legitimate stimulus of intellectual enthusiasm. And already in the *Theatetus* not love but wonder is described as the only beginning of philosophy.

While calling attention to this change of sentiment, it is right to add that Platonic love in the "erotic" dialogues of Plato is very different from what has often been so named, and that nothing even in the noble passage of the *Laws* above referred to casts the slightest shadow of blame on the Socrates of the *Symposium*.

Such changes are, amongst other things, a ground for caution in comparing the two steeds of the *Phaedrus* with the spirit (*θυμός*) and desire (*ἐπιθυμία*) of the *Republic* and *Timæus*. The *Phaedrus*, in common with these dialogues, asserts the existence of higher and lower impulses in human nature, but there is no sufficient ground for supposing that when Plato wrote the *Phaedrus* he would have defined them precisely as they are defined in the *Republic*.

The *Cratylus* is full of curious interest as marking the Cratylus highest point reached by the "science of language" in antiquity; but, as this dialogue "hardly derives any light from Plato's other writings,"<sup>2</sup> so neither does it reflect much light on them. It deals slightly with the contrast between Heracliteanism and Eleaticism, the importance of dialectic, the difficulty about the existence of falsehood, and ends with a brief allusion to the doctrine of ideas,—but these topics are all more fully discussed elsewhere.

<sup>1</sup> *Laws*, viii. 836.

<sup>2</sup> Professor Jowett,—who has, notwithstanding, thrown much light on the *Cratylus* in his brilliant introduction.

Three persons maintain different views respecting the nature and origin of language.

Hermogenes affirms that language is conventional, Cratylus (the Heraclitean) that it is natural. Socrates, mediating between these sophistical extremes, declares that language, like other institutions, is natural, and therefore (1) is based on nature, but (2) modified by convention.

In his dialectical treatment of the subject, Socrates displays a tissue of wild etymologies in reliance on the "inspiration" of Euthyphro. Presently a distinction appears between primary and secondary words. Many primary words convey the notion of movement and change. It follows that the legislator or word-maker held Heraclitean views. Socrates thus far presses on Hermogenes the view of Cratylus. Then turning to Cratylus he asks if there are no false names. "False language," Cratylus argues, "is impossible." Socrates shows that a true image may be inadequate, so that we have a right to criticize the work of the word-maker. And the facts indicate an element of meaningless convention. Nor was the original word-maker consistently Heraclitean. For some important words point not to motion but to rest.

But the question returns—Are we sure that the theory of nature which the word-maker held was true? This difficulty cannot be touched by verbal arguments. In seeking to resolve it we must consider, not words, but things. If there is a true beauty and a true good, which are immutable, and if these are accessible to knowledge, that world of truth can have nothing to do with flux and change.

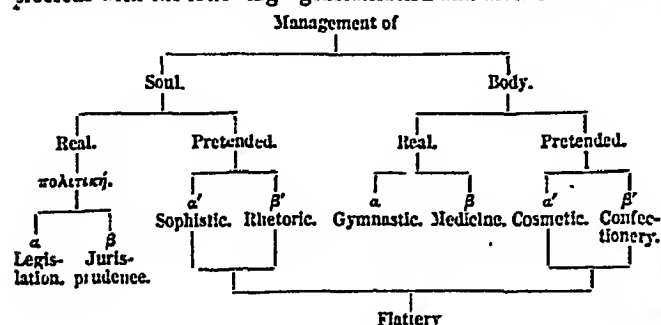

V. *Gorgias, Republic*.—In the *Symposium* and *Phaedrus* Plato largely redeems the promise implied in the *Phædo*, where Socrates tells his friends to look among themselves for a charmer who may soothe away the fear of death. But he was pledged also to a sterner duty by the warning of Socrates to the Athenians, in the *Apology*, that after he was gone there would arise others for their reproof, more harsh than he had been. To this graver task, which he had but partially fulfilled with the light satire upon Lysias or the gentle message to Isocrates, the philosopher now directs his powers, by holding up the mirror of what ought to be against what is, the principles of truth and right against the practice of men. For the good has more than one aspect. The beautiful or noble when realized in action becomes the just. And to the question, What is just? are closely allied those other questions of Socrates—What is a state? What is it to be a statesman?

In the *Gorgias* Plato asserts the absolute supremacy of justice through the dramatic portraiture of Socrates in his opposition to the world; in the *Republic* he strives at greater length to define the nature of justice through the imaginary creation of an ideal community.

*Gorgias*. In the former dialogue the Platonic Socrates appears in direct antagonism with the Athenian world. The shadow of his fate is hanging over him. Chærephon (who is still alive) understands him, but to the other interlocutors, Gorgias, Polus, Callicles, he appears perversely paradoxical. Yet he effectively dominates them all. And to the reader of the dialogue this image of "Socrates contra mundum" is hardly less impressive than that former image of Socrates confronting death.

1. Gorgias asserts that rhetoric is an art concerned with justice, and that persuasion is the secret of power.

a. Socrates, after suggesting some ironical doubts, declares his opinion that rhetoric is no art, but a knack of pleasing, or in other words "the counterfeit of a subsection of statesmanship." This oracular definition rouses the interest of Gorgias, and Socrates proceeds with the following "generalization and division":—

Flattery influences men through pleasure without knowledge. And the rhetor is a kind of confectioner, who can with difficulty be distinguished from the sophist.

3. Rhetoric, then, is not an art. And persuasion is not the secret of power. Here Socrates maintains against Polus the three paradoxes:—

The tyrant does what he chooses but not what he wishes;  
It is less evil to suffer wrong than to do wrong;

It is better for the wrongdoer to be punished than to escape punishment.

The only use of rhetoric, therefore, is for self-accusation, and (if it is ever permissible to do harm) to prevent the punishment of one's enemy.

2. Callicles here loses patience and breaks in. He proponnds his theory, which is based on the opposition of nature and custom.

"There is no natural right but the right of the stronger. And natural nobility is to have strong passions and power to gratify them. The lawful

Is a word that cowards use,  
Devised at first to keep the strong in awe."

Socrates entangles him in an argument in which it is proved that pleasure is different from good, and that there are good and bad pleasures.

Now the question is whether the life of philosophy, or the life which Callicles defends, is conducive to good. And it has been shown that rhetoric is one of a class of pursuits which minister to pleasure without discriminating what is good.

Callicles again becomes impatient. Did not Themistocles, Cimon, Pericles labour for their country's good? Socrates then renews his demonstration, proving that if the just man is wronged the evil lies with the wrongdoer, not with him, and that it is worst for the wrongdoer if he escape. And for avoidance of this greatest evil not rhetoric avails anything, nor any of the arts which save life (seeing that life may be used well or ill), nor even such an art of politics as Themistocles, Cimon, or Pericles knew, but another science of politics which Socrates alone of the Athenians practises. The pursuit of it may well endanger him; but his strength lies in having done no wrong. For in the world to come he can present his soul faultless before her judge. Not the show of justice but the reality will avail him there.

This truth is enforced by an impressive myth. And Callicles is invited to leave the life which relies on rhetoric and to follow Socrates in practising the life of philosophic virtue.

The value of justice has been shown. But what is justice? Is the life upheld by Socrates sufficiently definite for practical guidance? The views of Callicles have been overborne; but have they been thoroughly examined? Socrates claims to be the only politician. But how can that deserve the name of policy which results in doing nothing? These and cognate questions may well have haunted Plato when he planned the greatest of his works. *Republic*. For that which lay deepest in him was not mere speculative interest or poetic fervour, but the practical enthusiasm of a reformer. The example of Socrates had fired him with an ideal of wisdom, courage, temperance, and righteousness, which under various guises, both abstract and concrete, has appeared and reappeared in the preceding dialogues. But the more vividly he conceived of this ideal life, the more keenly he felt its isolation in the present world—that of the restored Athenian democracy. For to a Greek mind above all others life was nothing without the social environment, and justice, of all virtues, could least be realized apart from a community. Hence it became necessary to imagine a form of society in which the ideal man might find himself at home, a state to which the philosopher might stand in harmonious relationship, no longer as an alien sojourner, but as a native citizen, not standing aloof in lonely contemplation, but acting with the full consent of other men and ruling in the right of wisdom. Plato did not regard his own republic as a barren dream. He believed that sooner or later in the course of time a state essentially resembling his ideal commonwealth would come into being. Still more firmly was he convinced that until then mankind would not attain their highest possible development. To ignore this real aspect of his most serious work is to lose much of the author's meaning. Yet it is hardly less erroneous to interpret a great imaginative creation *au pied de la lettre*, as if exam-

ining a piece of actual legislation. Even in his *Laws*, a far more prosaic writing, Plato himself repeatedly protests against such criticism. In his most aspiring flights he is well aware of the difference between the imaginary and actual embodiment of an ideal,<sup>1</sup> although as a literary artist he gives to his creations, whether in anticipation or retrospect, an air of sober reality and matter-of-fact. He is more in earnest about principles than about details, and if questioned would probably be found more confident with regard to moral than to political truth. He may have been wholly unconscious of the inconsistencies of his scheme, but it would not have greatly disconcerted him to have discovered them, or to have been told that this or that arrangement would not "work." He would have trusted the correction of his own rough draft to the philosopher-kings of the future.

The *Republic* falls naturally into five portions. (1) Bk. i. is preliminary, raising the main question about justice. (2) Bks. ii., iii., iv. contain the outlines of the perfect state, including the education of the "guardians," and leading up to the definition of justice (a) in the state, and (b) in the individual. (3) Bks. v., vi., vii. (which to some critics present the appearance of an afterthought or excrescence on the original design) contain the cardinal provisions (1) of communism (for the guardians only), (2) that philosophers shall be kings, (3) of higher education for the rulers (viz., the philosopher-kings). This third provision occupies bks. vi. and vii. (which have again, as some think, the appearance of an outgrowth from bk. v.). (4) Bks. viii. and ix., resuming the general subject from bk. iv., present the "obverse side," by showing the declension of the state and individual through four stages, until in the life of tyranny is found the image of ideal injustice, as that of justice was found in the life of the perfect state. (5) Bk. x. forms a concluding chapter, in which several of the foregoing enactments are reviewed, and the work ends, like the *Gorgias*, with a vision of judgment.

Thus the main outlines of the scheme are contained in bks. ii., iii., iv., viii., ix. And yet bks. v., vi., vii. form the central portion, a sort of inner kernel, and are of the highest significance.

In speculating about the composition of the *Republic* (as is the fashion of some interpreters), it is important to bear in mind the general character of Plato's writings.

"The conception of unity," says Professor Jowett,<sup>2</sup> "really applies in very different degrees to different kinds of art,—to a statue, for example, far more than to any kind of literary composition, and to some species of literature far more than to others. Nor does the dialogue appear to be a style of composition in which the requirement of unity is most stringent; nor should the idea of unity derived from one sort of art be hastily transferred to another. . . . Plato subjects himself to no rule of this sort. Like every great artist he gives unity of form to the different and apparently distracting topics which he brings together. He works freely, and is not to be supposed to have arranged every part of the dialogue before he begins to write. He fastens or weaves together the frame of his discourse loosely and imperfectly, and which is the warp and which the woof cannot always be determined."

It should be added, that as Dialectic was still a "world not realized," and he was continually conscious of using imperfect methods, he was not solicitous to bind himself to any one method, or to watch carefully over the logical coherence of his work. "Sailing with the wind of his argument," he often tacks and veers, changing his method with his subject-matter, much as a poet might adopt a change of rhythm. Absorbed as he is in each new phase of his subject, all that precedes is cancelled for the time. And much of what is to come is deliberately kept out of view, because ideas of high importance are reserved for the place where their introduction will have most effect. Another cause of apparent inconsequence in Plato is what he himself would call the use of hypothesis. He works less deductively and more from masses of generalized experience than Platonists have been ready to admit. And in the *Republic* he is as much engaged with the criticism of an actual as with the projection of an ideal condition of society.<sup>3</sup> If we knew more of the working of

Attic institutions as he observed them, we should often understand him better.

These general considerations should be weighed against the inequalities which have led some critics to suppose that the "first sketch of the state" in bks. ii.-iv. is much earlier than the more exalted views of bks. v.-vii. If in these later books new conditions for choosing the future rulers are allowed to emerge, if in discussing the higher intellectual virtues the simple psychology of bk. iv. is lost sight of (it reappears in the *Timæus*), if the "knowledge of the expedient" at first required falls far short of the conception of knowledge afterwards attained, all this is quite in keeping with Plato's manner elsewhere, and may be sufficiently accounted for by artistic and dialectical reserve. It can hardly be an altogether fortuitous circumstance that the culminating crisis, the third and highest wave of difficulty,—the declaration that philosophers must be kings and kings philosophers,—comes in precisely at the central point of the whole long work.

The great principle of the political supremacy of mind, though thus held back through half the dialogue, really dominates the whole. It may be read between the lines all through, even in the institution of gymnastic and the appraisal of the cardinal virtues. It is a genuine development of Socratic thought. And it is this more than any other single feature which gives the *Republic* a prophetic significance as "an attempt towards anticipating the work of future generations."<sup>4</sup>

Other aspects of the great dialogue, the Dorian framework, so inevitable in the reaction from Ionian life, the traces of Pythagorean influence, the estimate of oligarchy and democracy, the characters of the interlocutors in their bearing on the exposition, have been fully treated by recent writers, and for brevity's sake are here passed over. There are other points, however, which must not be omitted, because they are more intimately related to the general development of Plato's thoughts.

1. The question debated by Proclus has been raised before and since, whether the proper subject of the *Republic* is justice or the state. The doubt would be more suggestive if put in a somewhat different form: Is Plato more interested in the state or the individual? That he is in earnest about both, and that in his view of them they are inseparable, is an obvious answer. And it is almost a truism to say that political relations were prior to ethical in the mind of a Greek. Yet if in some passages the political analogy reacts on moral notions (as in the definition of temperance), in others the state is spoken of in language borrowed from individual life. And it remains questionable whether the ethics or the politics of the *Republic* are less complete. On the whole Plato himself seems to be conscious that the ideal derived from the life-work of Socrates could be more readily stamped on individual lives than on communities of men (see especially *Rep.*, vii. 528 A, ix. 592).

2. The analogy of the individual is often used to enforce the requirement of political unity and simplicity (see especially v. 462 C). This is also to be referred, however, to Plato's general tendency to strain after abstractions. He had not yet reached a point of view from which he could look steadily on particulars in the light of universal principles. He recurs often to experience, but is soon carried off again into the abstract region which to him seemed higher and purer.<sup>5</sup> "It has been said that Plato flies as well as walks, but this hardly expresses the whole truth, for he flies and walks at the same time, and is in the air and on firm ground in successive instants" (Jowett).

<sup>1</sup> See especially *Rep.*, v. p. 472; *Legg.*, v. p. 746.

<sup>2</sup> Jowett, *Intro.* to the *Phædrus*.

<sup>3</sup> Krohn, *Der Platonische Staat*, Halle, 1876.

<sup>4</sup> Grote.

<sup>5</sup> See, for example, the admission of luxury and the after-purification through "music," bks. ii., iii.

Plato's scheme of communism had been suggested to him partly by Dorian institutions and partly by the Pythagorean rule. But it was further commended by the general consideration that the state is a higher and more abstract unity than the family. The lower obligation must give way to the higher; the universal must overrule the particular bond.

3. Similarly it may be argued that, while the subordination of music to state discipline, and the importance attached to rhythm and harmony in education, had likewise a connexion with Sparta and the Pythagoreans severally, Plato's deliberate attitude towards poetry and art could hardly be other than it is. Philosophy, while still engaged in generalization, could not assign to the imagination its proper function. "Æsthetik" could not enter into her purview. For a moment, in the *Symposium*, the ancient quarrel of poetry and philosophy had seemed to be melted in a dominant tone, but this was only a fond anticipation. Plato, if man ever did so, had felt the siren charm, but he is now embarked on a more severe endeavour, and, until the supreme unity of truth and good is grasped, vagrant fancy must be subdued and silent.

4. In the early education of the guardians a place is found for the unconscious virtue acquired through habit which the *Protagoras* and *Meno* stumbled over and the *Phædo* treated with disdain. In the ideal state, however, this lower excellence is no longer a wild plant, springing of itself through some uncovenanted grace of inspiration, but cultivated through an education which has been purified by philosophy so as to be in harmony with reason. But if Plato were cross-questioned as to the intrinsic value of habits so induced as a preservative for his pupils against temptation, he would have replied, "I do not pretend to have removed all difficulties from their path. Enough of evil still surrounds them to test their moral strength. I have but cleared the well-springs of the noxious weeds that have been fatal to so many, in order that they may have little to unlearn, and be exposed only to such dangers as are inevitable."

5. It is a singular fact, and worth the attention of those who look for system in Plato, that the definition of justice here so laboriously wrought out, viz., the right division of labour between the three classes in the state and between the three corresponding faculties in the individual soul, is nowhere else repeated or applied, although the tripartite division of the soul recurs in the *Timæus*, and the notion of justice is of great importance to the arguments of the *Politicus* and the *Laws*.

6. Before leaving the *Republic*, it is important to mark the stage which has now been reached by Plato's doctrine of ideas. The statements of the *Republic* on this subject are by no means everywhere consistent.

a. Towards the end of bk. v. philosophers are defined as lovers of the whole, who recognize the unity of justice, goodness, beauty, each in itself, as distinguished from the many just or good or beautiful things. The former are said to be objects of knowledge, the latter of opinion, which is intermediate between knowledge and ignorance. Knowledge is of being, ignorance of the non-existent, opinion of that which is and is not.

b. In bk. vi. there is a more elaborate statement, implying a more advanced point of view. The "contemplation of all time and all existence" is a riper conception than "the love of each thing as a whole." Ignorance and nonentity have now disappeared, and the scale is graduated from the most evanescent impression of sense to the highest reach of absolute knowledge. And in the highest region there is again a gradation, rising to the form of good, and descending from it to the true forms of all things. In the application of this scheme to the theory

of education in bk. vii. there are still further refinements. The psychological analysis becomes more subtle, and more stress is laid on the connexion of ideas.

c. The doctrine reverts to a cruder aspect in bk. x., where we are told of an ideal bed, which is one only and the pattern of all the many actual beds.

d. A yet different phase of idealism presents itself in bk. ix. (*sub fin.*), in the mention of a "pattern" of the perfect state laid up in heaven which the philosopher is to make his rule of life.

What is said above concerning Plato's mode of composition has some bearing on these inconsistencies of expression. And that bks. vi., vii., as being the most important, were finished last is a not untenable hypothesis. But that Plato, in preparing the way for what he had in contemplation, should content himself with provisional expressions which he had himself outgrown, or that in a casual illustration (as in bk. x.) he should go back to a crude or even childish form of his own theory, is equally conceivable and in accordance with his manner elsewhere. Socrates in the *Parmenides* confessedly wavers on this very point. And there are "ideas" of the four elements in the *Timæus*.

VI. *Euthydemus*, *Parmenides*, *Theætetus*, *Sophist*, *Statesman*, *Philebus* (the dialectical dialogues).—Even in the most advanced metaphysics of the *Republic* there is a hyperbolic, transcendental tendency, from which Plato ultimately to some extent worked himself free. But it was not in conversation with "dear Glaucon," or "between the lines" of an ethico-political writing, that this partial emancipation could be effectually attained. We have now to consider a series of dialogues, probably intended for a narrower circle of readers, in which Plato grapples directly with the central difficulties of his own theory of knowing and being. It is not necessary to assume that all of these are later than the *Republic*. The position of the *Euthydemus* and *Parmenides* in the order of composition is very uncertain. The *Theætetus* has points of affinity with the *Republic*. The *Sophist*, *Politicus*, and *Philebus* are in a later style. But, on account of their cognate subject-matter, these six dialogues may be conveniently classed together in a group by themselves. And the right place for such a group is intermediate between the *Republic* and the *Laws*.

The unity of the object of definition, the identity of virtue and knowledge, the existence of an absolute good, which would be universally followed if universally known, and of a standard of truth which is implied in the confession of ignorance, were postulates underlying the Socratic process, which in so far made no claim to be a "philosophy without assumptions." These postulates, when once apprehended, drew Plato on to speculate concerning the nature, the object, and the method of knowledge. Now, so far as we have hitherto followed him, his speculation has either been associated with ethical inquiry, or has been projected in a poetical and semi-mythical form. In the *Phædrus*, however, the vision of ideas was expressly conjoined with an outline of psychology and a foreshadowing of scientific method. And, while the opposition of ideas to phenomena and of knowledge to opinion has been repeatedly assumed, it has also been implied that there is a way between them, and that the truth can only be approached by man through interrogation of experience. For it is nowhere supposed that the human inquirer is from the first in a position to deduce facts from ideas. Much rather, the light of the ideas is one which fitfully breaks in upon experience as men struggle towards the universal.

But it is not less true that the metaphysical aspirations from which Socrates had seemed to recall men's thoughts had been reawakened in consequence of the impulse which

Socrates himself had given. From asking, Is virtue one? Can virtue be taught? Plato passes on to ask, What is unity? What are knowledge and being? From criticizing imperfect modes of teaching virtue, he has begun to speculate about the right and wrong uses of the intellect, and from dramatic portraits of the individual Protagoras or Gorgias goes on to the ideal delineation of the sophist. He has entered upon the "longer way," and is no longer contented with mere "hypotheses." With this demand for scientific precision his conception of the ideas themselves is modified, and he strives anew to conceive of them in relation to one another, to the mind, and to the world. As the balance of ethical truth was restored by admitting an unconscious (or inspired) conformity to reason, so now a fresh attempt is made on the intellectual side to bridge the gulf between sense and knowledge:

This endeavour involves, not only an expansion of the method of Socrates, but an examination of the earlier philosophies from which Socrates had turned away. Their influence on Plato has been traceable in the preceding dialogues, though, except in the case of Pythagoreanism (*Phaed.*, *Rep.*), it has been mostly indirect and casual. But in these dialectical dialogues he manifests his serious conviction that the contemporary fallacies which formed the chief hindrance to inquiry were deeply rooted in forms of thought created by earlier thinkers, above all by Heraclitus and Parmenides. To the exclusiveness of their first principles as held by their followers Plato attributed the barrenness and impracticable unreality of many discussions, which put shadow-fighting and controversy in the place of real investigation, and led men to think that truth was unattainable. He therefore enters into conversation, as it were, with the great minds of former times, and in the spirit of Socrates compels each of them to yield up his secret, and to acknowledge a supplemental truth. To this effort he may very probably have been stimulated by the dialectical activity of his Socratic friends at Megara, whose logical tastes had drawn them towards Eleaticism. But, unlike them, while strengthening his metaphysical theory, he was also led to give to his political speculations a more practical turn.

Euthydemus.

The *Euthydemus* is a treatise "De Sophisticis Elenchis" in the form of a farce, and may serve to introduce the five other dialogues, as the encounter with Thrasymachus introduces the serious part of the *Republic*. Under the veil of mockery there is more of concentrated thought, and also more of bitterness, in this dialogue than in the *Protagoras* or the *Gorgias*.

A sample of educational dialectic—in which Socrates draws out of young Clinias the admissions (1) that a philosophy is needed, (2) that the highest philosophy is a science of king-craft, which remains for the present undefined,—is contrasted with a series of ridiculous sophisms, propounded by Dionysodorus and his brother Euthydemus, in which absolute and relative notions, whether affirmative or negative, object and subject, universal and particular, substance and attribute, action and modality, are capriciously confused. Crito, to whom Socrates narrates the scene, is moved to contempt. But Socrates warns him not on this account to despair of philosophy. In conclusion, Isocrates, or some one else, who prematurely mixes up philosophy with practical politics, is cautioned against spoiling two good things.

Such puzzles as—How can I learn either what I know or what I do not know?<sup>1</sup> How can things become what they are not? How is falsehood or denial possible?—although treated jocularly here, will be found returning afterwards to "trouble the mind's eye."

Plato appears in the same act to have become aware of Parmenides' affinity with Parmenides, and to have been led to reconsider the foundations of his own doctrine. The one being of Parmenides was a more abstract notion than justice, beauty, or the good. And the Zenonian method had more pretension to exactness than the Socratic. But it remained barren, because contented to repeat its own first essays in the destructive analysis of experience, without rising to the examination of its own first principles. For this higher criticism, of which he himself also stood in need, Plato looks up from the disciples to the master, Parmenides. The appeal to him is put into the mouth of Socrates, as a very young man, who has framed for himself a theory of ideas, and would gladly see the Zenonian process applied to the notions of sameness, difference, likeness, unlikeness, unity, and being.

Parmenides, whom Plato treats with tender reverence not unmixed with irony, proposes to the youth a series of questions which reveal the crudity of the doctrine of *εἶδη*. (1) Are there ideas of trivial things?<sup>2</sup> (2) How do things "partake" of them? (3) Must not idealism proceed *in infinitum*? (4) If ideas are thoughts, do they and their participants think? (5) If they are patterns, and things resemble them, must there not be a pattern of the resemblance, and so on *in infinitum*? (6) If absolute, are they thinkable by man?

These difficulties are real, and yet to deny ideas is to destroy philosophy. (As the paradoxical doubts in the *Protagoras* do not shake the faith of Socrates in the existence of good, so neither does Plato here intend for a moment to derogate from the belief in the existence of the One and the True.)

Parmenides advises Socrates to arm himself for the further pursuit of truth (1) by the higher application and (2) by the extension or completion of the Zenonian method. (1) The method is to be applied to abstractions. (2) It is not enough to show the inferences which may be drawn from the admission of an hypothesis, but account must also be taken of the inferences which follow from its rejection.

Parmenides exemplifies his suggestion by examining his own first principle in conversation with a youth who, while a contemporary of Socrates, is a namesake of Plato's pupil Aristotle.<sup>3</sup> Not content with the affirmative and negative hypotheses, he pursues either along two lines, according as either term of the proposition is emphasized, and this not only as regards the hypothesis of unity, but also as applied to the alternative hypothesis of plurality. The result, as in the *Protagoras*, is purely destructive, and the dialogue ends abruptly without a word of reply from Socrates.

The second part of the *Parmenides* may be regarded as an experiment in which Plato "assays to go" in Eleatic armour. Yet the strange web is "shot" with colours of original thought. The mode of conceiving time and becoming, and the vision of nothingness towards the end, may be noted as especially Platonic. These passages may be regarded in the same light as the wise words of Protagoras or the sober truths which occur amidst the wild fancies of the *Cratylus*. They should not mislead the interpreter into a search for recondite meanings.

The Zenonian method has been carried out to the utmost in application to the highest subject, and has led the mind into a maze of contradiction. It remains to call in question the method itself, and the notion of absolute identity and difference on which it hinges, and so to lay anew the foundation-stone of thought.

Before this can be attempted, however, another set of difficulties have to be met, and another set of philosophers examined. For the current scepticism had undermined the conception of knowledge as well as that of being, and the fame of Heraclitus was hardly second to that of Parmenides. Protagoras appeared in a former dialogue as

<sup>1</sup> Comp. *Meno*.

<sup>2</sup> Comp. *Rep.*, x, 597.

<sup>3</sup> Comp. the younger Socrates of the *Politicus*. It would be precarious to draw any inference from this minute fact.

**Theaetetus** the champion of ordinary morality; he is now made the exponent of ordinary thinking. His saying "Man the measure" is shown to rest on the unstable basis of the Heraclitean flux. By an elaborate criticism of both theories knowledge is at last separated from the relativity of sense; but the subsequent attempt to distinguish on abstract grounds between true and false opinion, and to define knowledge as true opinion with a reason (comp. *Meno*), proves ineffectual. Plato still shows traces of Megarian influence. But the disjunctive method of the *Parmenides* is not resumed. The indirect proofs are so arranged as to exhibit the skill of Socrates in "bringing to the birth" the germs of thought in a richly-endowed and "pregnant" young mind. Theaetetus is the embodiment of the philosophic nature described in *Rep.*, bk. vi., and has already been trained by Theodorus of Cyrene in geometry and the other preparatory sciences of *Rep.*, bk. vii. It is in conversation with Theodorus that Socrates impressively contrasts the lives of the lawyer and the philosopher. The *Theaetetus* marks a great advance in clearness of metaphysical and psychological expression. See for example the passage (184-186) in which the independent function of the mind is asserted, and ideas are shown to be the truth of experience. There is also a distinct approach towards a critical and historical method in philosophy, while the perfection of style continues unimpaired, and the person of Socrates is as vividly represented as in any dialogue.

Notwithstanding the persistence of an indirect and negative method, the spirit of this dialogue also is the reverse of sceptical. "Socrates must assume the reality of knowledge or deny himself" (197 A). Perhaps in no metaphysical writing is the balance more firmly held between experience, imagination, and reflexion. Plato would seem to have made a compact with himself to abstain rigidly from snatching at the golden fruit that had so often eluded his grasp, and to content himself with laboriously "cutting steps" towards the summit that was still unscaled.

**Sophist.** With Plato, as with other inventive writers, a time seems to have arrived when he desired to connect successive works in a series. Thus in planning the *Sophistes* he linked it to the *Theaetetus* (which had been written without any such intention), and projected a whole tetralogy of dialectical dialogues. *Theaetetus*, *Sophistes*, *Politicus*, *Philosophus*, of which the last piece seems never to have been written.

After an interval, of which our only measure is a change of style, the philosopher returns to the great central question of knowledge and being. The obstacle in his path, on which he has often played with light satire, dramatic portraiture, and indirect allusion, is now to be made the object of a seriously planned attack. He has made his approaches, and the enemy's fortress is to be forthwith sapped and overthrown. This hostile position is not merely the "Sophistik" which, as some tell us, is an invention of the Germans, and as Plato himself declares is only the reflexion or embodiment of the average mind,<sup>1</sup> but the fallacy of fallacies, the prime falsehood (*πρωτον ψευδος*) of all contemporary thought. This is nothing else than the crude absoluteness of affirmation and negation which was ridiculed in the *Euthydemus*, and has been elsewhere mentioned as the first principle of the art of controversy.<sup>2</sup> For dramatic purposes this general error is personified. And the word "sophist," which had somehow become the *bête noire* of the Platonic school, thus for the first time fixedly acquires the significance which has since clung to the name.—That Plato himself would not adhere pedantically to the connotation here implied is shown by

the admission, at the opening of the dialogue, that amongst other disguises under which the philosopher walks the earth, the sophist is one.—In this dialogue, as in the *Parmenides*, a new method is introduced, and again by an Eleatic teacher. This method is repeated with improvements in the *Politicus*, and once more referred to in the *Philebus*. It bears a strong resemblance to the "synagoge" and "diæresis" of the *Phaedrus*, but is applied by the "friend from Elea" with a degree of pedantry which Socrates nowhere betrays. And the two methods, although kindred, have probably come through different channels,—the classifications of the *Phaedrus* being Plato's own generalization of the Socratic process, while the dichotomies of the *Sophistes* and *Politicus* are a caricature of Socrates cast in the Megarian mould. Plato seems to have regarded this method as an implement which might be used with advantage only when the cardinal principles on which it turned had been fully criticized.

1. After various attempts to "catch the sophist," he is defined as the maker of an unreal likeness of truth. Here the difficulty begins—for the definition implies the existence of the unreal, i.e., of not-being. In our extremity it is necessary to "lay hands on our father Parmenides."

2. The contradictions attendant on the notion of "being," whether as held by Parmenides or his opponents or by the "less exact" thinkers who came after them, are then examined, and in an extremely subtle and suggestive passage (246-249) an attempt is made to mediate between idealism and materialism. The result is that while consummate being is exempt from change it cannot be devoid of life and motion. "Like children, 'Give us both,' say we."

3. This leads up to the main question:—(a) are different notions incommunicable, or (b) are all ideas indiscriminately communicable, or (c) is there communion of some kinds and not of others? The last view is alone tenable, and is confirmed by experience. And of the true combination and separation of kinds the philosopher is judge.

4. Then it is asked (in order to "bind the sophist") whether being is predicable of not-being.

Five chief kinds (or categories) are now examined, viz., being, rest, motion, sameness, difference. Rest and motion are mutually incommunicable, but difference is no less universal than being itself. For everything is "other" than the rest, i.e., is not. Thus positive and negative not only coexist but are coextensive.

5. And, in spite of Parmenides, we have discovered the existence, and also the nature, of not-being. It follows that the mere pursuit of contradictions is childish and useless and wholly incompatible with a philosophic spirit.

Negation, falsity, contradiction, are three notions which Plato from his height of abstraction does not hold apart. His position is the converse of the Spinozistic saying, "Omnis determinatio est negatio." According to him, every negative implies an affirmative. And his main point is that true negation is correlative to true affirmation, much as he has said in the *Phaedrus* that the dialectician separates kinds according to the "lines and veins of nature." The *Sophistes* is a standing protest against the error of marring the finely-graduated lineaments of truth, and so destroying the vitality of thought.

The idealists whom the Eleatic stranger treats so gently have been identified with the Megarians. But may not Plato be reflecting on a Megarian influence operating within the Academy?

Here, as partly already in the *Parmenides* and *Theaetetus*, the ideas assume the nature of categories, and being is the sum of positive attributes, while negation, as the shadow of affirmation, is likewise finally comprehended in the totality of being.

The remark made incidentally, but with intense emphasis, that the universe lives and moves "according to God," is an indication of the religious tone which reappears increasingly in the *Politicus*, *Philebus*, *Timaeus*, and *Laws*.

In passing on to consider the statesman, true and false, *Politicus* the Eleatic stranger does not forget the lesson which has (Statesman.) just been learned. While continuing his method of dicto-

<sup>1</sup> *Rep.*, vi. 493.

<sup>2</sup> *ἁπλολογία*.

tomies, he is careful to look on both sides of each alternative, and he no longer insists on dividing between this and not-this when another mode of classification is more natural. A rule not hitherto applied is now brought forward, the rule of proportion or right measure (τὸ μέτρον), as distinguished from arbitrary limitations. Nor is formal logical treatment any longer felt to be adequate to the subject in hand, but an elaborate myth is introduced. On the ethico-political side also a change has come over Plato. As he has stripped his ideas of transcendental imagery, so in reconsidering his philosopher-king he turns away from the smiling optimism of the *Republic* and looks for a scientific statesmanship that shall lay a strong grasp upon the actual world. He also feels more bitterly towards the demagogues and other rulers of Hellas. The author of the *Politicus* must have had some great quarrel with mankind. But so far as they will receive it he is still intent on doing them good.

1. The king is first defined as a herdsman of men, who as "slow bipeds" are distinguished from the pig and the ape. But the king is not all in all to his charges, as the herdsman is. The above definition confuses human with divine rule.

2. Now the universe is like a top, which God first winds in one direction and then leaves to spin the other way. In the former or divine cycle all was spontaneous, and mankind, who had all things in common, were under the immediate care of gods. They were happy, if they used their leisure in interrogating nature. But in this reign of Zeus it is far otherwise. Men have to order their own ways and try to imitate in some far-off manner the all-but forgotten divine rule.

3. Therefore in our present definition the term "superintendent" must be substituted for "herdsman."

What special kind of superintendence is true statesmanship?
